VACCINATION GRANT.—Dr. Yarrow, public vaccinator for the St. Luke's division of the Holborn Union, has been awarded the Government grant for efficient vaccination for the third time.

AT Gillingham, on the 4th inst., a child aged nine years was in the act of inflating a toy balloon, when, suddenly trying to reverse the operation by sucking the air back, the toy was drawn down the child's throat, causing suffocation. A similar case is reported to have occurred in the same neighbourhood within the past month.

ALLEGED DEATH FROM SEA-SICKNESS.—Early this week an elderly female named Watson, a steerage passenger from Fleetwood to Belfast, was taken ill during the voyage, and when she reached the latter place she was found to be unconscious. She was removed to the Royal Hospital, but she died the same day.

BIRMINGHAM MEDICAL INSTITUTE.—The officers of the institute elected at the recent annual meeting are Professor Vose Solomon, President; Dr. Thomas Savage and Mr. C. A. Newnham, Vice-Presidents; Dr. Robert Saundby and Mr. Bennett May, Hon. Librarians; Mr. Gilbert Barling and Mr. Wood White, Hon. Secretaries.

ABERDEEN HOSPITAL FOR INCURABLES.—The annual meeting of the managers of and subscribers to this institution was held on the 1st inst., when the report showed that the average number of patients during the past year had been 38. The ordinary expenditure amounted to £1000, and the income, excluding legacies, to £751. The cost of the new buildings has exceeded the amount received for the old premises by nearly £3000. The committee appeal for fresh and increased subscriptions.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—A statue of Mr. William Dease, who was President in 1789 and died in 1798, will in a few weeks be erected in the entrance hall of this College. The statue, which is life size, has been executed in Carrara marble by Mr. Thomas Farrell, R.H.A., the eminent sculptor, and represents the deceased surgeon in the costume of the time in which he lived. He is seated in a chair holding in one hand a volume of his writings. The pedestal is already in position in the hall, and is formed of Sicilian marble. We may add that the cost of the statue has been defrayed by a grandson of Mr. Dease.

YORKSHIRE NORTH RIDING INFIRMARY.—The annual court of governors of this institution was held at Middlesborough on the 1st inst., when the committee reported that the number of patients admitted during the past year was 545, against 494 in 1884, the opening of the children's ward in November accounting for a portion of the excess. The number of out-patients again showed a very decided increase—viz., from 1419 in 1884, making 9034 attendances, to 1811 in 1885, with 13,863 attendances. The subscriptions and donations amounted to £2914 and the expenditure to £2930. The report and balance sheet having been adopted an illuminated address was presented to Dr. Williams, one of the hon. medical staff of the institution, in recognition of his valuable services during the past 15 years.

THE LATE DR. BRONNER.—On the 6th inst., at a well attended meeting held at Bradford, it was resolved:—"That this meeting desires in some public manner to express its sense of the eminent services of the late Dr. Bronner in connexion with the medical institutions of the town, and especially the Eye and Ear Hospital, which he was instrumental in establishing; and to which he gave his untiring attention to the day of his death; that a subscription list be opened, with the view, in the first instance, of raising funds to clear off the debt on the building of the above-named hospital, and, in the next place, of founding a laboratory for scientific purposes in connexion with the hospital, this meeting feeling assured that the late Doctor had these objects nearest his heart." A committee was appointed to give effect to this resolution, and a sum of upwards of £1000 was subscribed in the room.

HEALTH OF BELFAST.—During the five weeks ending the 27th ult. there were 335 fatal cases of diseases of the lungs, a number equal to a rate of 14·4 per 1000. This excessive mortality may be mainly attributed to the inclemency of the weather during the month of March.

INSTITUTE OF ACTUARIES.—At a meeting held at the rooms of the institute, Adelphi-terrace, on the 29th ult., Mr. James Chisholm, F.I.A., read a paper criticising the method in use by Life Assurance Companies of adding a number of years to the age of a person proposing to assure his life, to compensate for supposed extra risk due to impaired health or imperfect family history. Mr. Chisholm contended that the method in question was based on an incorrect theory, and was moreover misleading in practice. He made suggestions, illustrated by a diagram, for obtaining the opinion of medical examiners in a more accurate way, and expressed the opinion that it was very desirable that assurance companies should adopt as far as possible one common form of medical report. Several members of the medical profession were present, some of whom took part in the discussion which followed the reading of the paper.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANDERSON, JOHN, M.B., C.M.Aber., has been appointed Medical Assistant at Elmhill House Asylum, Aberdeen, vice Sinclair, resigned.

BEVERS, E. A., M.R.C.S., L.S.A.Lond., has been appointed Consulting Dental Surgeon to the Radcliffe Infirmary, Oxford.

COMBES, REGINALD H., M.R.C.S., L.R.C.P.Lond., has been appointed Resident Medical Officer to the North-West London Hospital.

HALLIBURTON, W. D., M.D., B.Sc., M.R.C.P., Sharpey Physiological Scholar, has been appointed Assistant Professor of Physiology to University College, London.

HUTTON, HENRY R., M.A., M.B.Cantab., has been appointed Honorary Physician to the Ancoats Hospital, Manchester.

KUTTLITZ, REGINALD, M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Hamsterly District of the Auckland Union.

PERKINS, H. A., M.D.Ed., M.R.C.S., has been appointed President of the Central Board of Health of Tasmania.

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—On the 6th inst., at 105, Gloucester-place, Portman-square, the wife of John Anderson, M.D., C.I.E., Brigade-Surgeon, retired, of a daughter.

COTTELL.—On the 30th ult., at Old Brompton, Kent, the wife of Surgeon A. Cottell, Medical Staff, of a daughter.

EVANS.—On the 24th ult., at 21, Charles-street, Cardiff, the wife of Dr. Frederick William Evans, of a son.

MARRIAGES.

DAVIDSON—HENDERSON.—On the 6th inst., at St. Augustine's, Forest-hill, James McKenzie Davidson, M.B., C.M., of Aberdeen, to Georgiana Barbara Watt, daughter of the late W. Henderson, of Aberdeen.

GROOM—CHAPMAN.—On the 6th inst., at Brussels, Harry Groom, M.B., M.R.C.S., L.S.A.Lond., B.A., of Wisbeach, to Rebecca (Minnie), third daughter of William Chapman, Esq., of Antwerp.

MARSH—HOOPER.—On the 30th ult., at Holy Trinity Church, Clapham, Frank Marsh, F.R.C.S.Eng., of Grasmere, Rolton-park-road, Edgbaston, late of Stafford, to Annie Constance, youngest daughter of the late William Hooper, of Beechwood, Clapham-common.

DEATHS.

MANLEY.—On the 5th inst., at Ipplepen, Devon, Henry Manley, M.R.C.S., L.A.C., aged 58.

PETT.—On the 3rd inst., at his residence, Avenue-road, Regent's-park, Alfred Pett, M.D., in his 82nd year.

RAWLINS.—On the 2nd inst., Frederick William Armstrong Rawlins, M.D., late of Stoke Newington, aged 59.

RICHARDS.—On the 1st inst., Owen Richards, M.D, of Vronheulog, Llandderfel, formerly of Bala, aged 73.

SKEEN.—On the 2nd inst., at Westfield-terrace, Aberdeen, Deputy Surgeon-General William Skeen, M.D., Army Medical Staff, aged 53.

THOMSON.—On the 28th ult., at Aldershot, Surgeon-Major A. Thomson, M.D., Army Medical Staff, aged 45.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 12.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Mr. Alan S. Cole: The Arts of Tapestry-making and Embroidery (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Cases will be shown by the President, Dr. Ord, Dr. Stephen Mackenzie, Dr. Purcell, Mr. John Morgan, and others.

Tuesday, April 13.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Mr. W. H. Stone: Man as an Electric Conductor, Condenser, and Electrolyte (Lumleian Lecture).
SOCIETY OF ARTS.—8 P.M. Mr. P. L. Simmonds: Progress of the British Possessions in the last Quarter of a Century.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Sedgwick: The Chemical Pathology of Respiration in Cholera.—Mr. Knowsley Thornton: Two cases of Splenectomy.

Wednesday, April 14.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
HUNTERIAN SOCIETY.—8 P.M. Mr. Bryant: Cystic Tumours of the Breast.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr James Cameron: Observations on a Certain Malady occurring among Cows at a time when the Milk produced by them disseminated Scarlatina.—Dr. Buchanan: Certain Alleged Injuries by Vaccination in North Germany.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. G. Massee: Structure and Evolution of the Florideæ.
SOCIETY OF ARTS.—8 P.M. Dr. C. Meymott Tidy: The Treatment of Sewage.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Greig Smith, George Miller, and others.—Dr. Robert Barnes: Vicarious Menstruation.

Thursday, April 15.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: Electro-Chemistry.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. W. H. Stone: Man as an Electric Conductor, Condenser, and Electrolyte (Lumleian Lecture).
PARKES MUSEUM OF HYGIENE.—8 P.M. Rev. F. Lawrence: Eramscausis, Sanitary Burials.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. Broadbent: Case of Bulbar Paralysis.—Dr. Stephen Mackenzie: An Unusual case of Pemphigus.—Mr. A. J. Pepper: A case of Excision of the Knee-joint.—Mr. Winslow Hall: Specimen of Congenital Malformation of the Heart.—Also cases by Mr. Jonathan Hutchinson, Dr. Hughlings Jackson, Mr. H. E. Juler, and Mr. Noble Smith.

Friday, April 16.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Prof. Bischof: Dr. Koch's Gelatine-Peptone Test for Water.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. Sir Henry E. Roscoe: Recent Progress in the Coal Tar Industries.

Saturday, April 17.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Oliver Lodge: Fuel and Smoke.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

LUNACY LAW REFORM.

A. H. B.—We must adhere to the expressed opinion that it is very undesirable that medical practitioners should derive profit from lodging the insane in their houses; and to the view that single patients are not, as a rule, well placed. It is no part of our contention that the treatment of lunacy must be carried on by specialists. Our readers generally will not fail to know that we claim for the profession as a whole the right to practise every branch of the art of healing. The opinions we have formed on this subject are based on observation and experience, and we must be excused for feeling strongly, and saying plainly, that when the subjects of mental disease are removed from the immediate care of their friends, it is better that they should be placed in the custody of public officials responsible to the State, and who derive no pecuniary advantage from receiving the individuals under their care.

Festina.—The question can hardly be answered without having read the tracts; but we do not see anything to object to in the advertisement itself.

Mr. E. Bingham.—The lists are published in THE LANCET weekly.

THE LIBRARY OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—There is really no excuse for the discourtesy which is shown the Fellows and Members of the College of Surgeons who use the library of that institution by some official persistently neglecting to forward to the medical journals intimation of the times when the library will be closed. There has been no mention of the date of the expected opening of the building upon the Embankment, consequently there is still, it is presumable, plenty of time to take happy "constitutionals" to the library of the College of Surgeons, fruitless though they may be, in regard to the object for which they are undertaken. But the sooner the Hall is opened the better, for then the classic walls of the College Hall will cease to re-echo whispered epithets of doubtful politeness let loose by disappointed workers.

I am, Sir, yours truly,

Finsbury-circus, E.C., March 20th, 1886. H. PERCY DUNN.

PRINCELY BEQUESTS.

To the Editor of THE LANCET.

SIR,—Many of the readers of THE LANCET will be glad to hear that the late Mr. John Smith, a much esteemed medical practitioner of Bishop's Lydeard, Somerset, has by will given to the Taunton and Somerset Hospital the sum of £1000, payable on the decease of his wife. In addition to this sum, the same gentleman has bequeathed to the Royal Medical Benevolent College at Epsom (after the decease of his wife) a sum of money not far short of £10,000.

I am, Sir, your obedient servant,

Taunton, April 4th, 1886. ARTHUR KINGLAKE, J.P.

A DESCRIPTIVE TITLE FOR A PHARMACIST.

SOME misunderstanding exists amongst the public as to the signification of "chemist" and "apothecary." A suggestion has been made by a German, who objects to the word "apotheker" as of foreign origin, that the Teutonic pharmacist should be styled "Gesundheitswieder-herstellungsmittelzusammenmischungskundiger."

Alpha.—A fee cannot be claimed.

WARLOMONT'S MANUAL OF ANIMAL VACCINATION.

To the Editor of THE LANCET.

SIR,—Being away from home, I have only just observed in THE LANCET of Feb. 13th and 20th the notice of this Manual which you were good enough to insert, and Dr. Harries' reply to some points in that notice.

I respect the rights of criticism, especially when, as in your esteemed journal, reply is permitted. Here is mine. Your reviewer is disappointed at not having found "more exact evidence.....calf vaccine." He is exacting; the author has fully described the principles of the processes hitherto used by him. As to the comparative value of his preparations, it is the medical world that must decide; it, at least, cannot be unaware of the considerable use made of them in the United Kingdom and in the colonies, and nothing could speak more eloquently. As to statistics, Dr. Harries has already shown with what facility they may be distorted. I have stated, and I repeat, that *living* vaccine, human or animal, is always more certain, so far as concerns its *immediate manifestations*, than *preserved vaccine*. Only, as vaccination from arm to arm is mistrusted by most people, and as that from calf to arm is as yet uncommon in general practice, it was necessary to find a preparation which should most nearly approach that certainty, and that is what I have attempted. The favour with which my "emulsion" has been received proves that I have not come far short of the ideal. As to the question of learning whether human lymph can bear comparison with this last in the matter of carriage to great distances, I believe that to be finally determined. It is only *very exceptionally* that human vaccine reaches remote regions in a state of activity, whilst the applications that I am constantly receiving from the Congo prove that my "emulsion," as a rule, arrives there in a state of complete activity.

Whatever may be the merit of my little work, your reviewer recognises none. That is not much! "There is little," he says, "scientific work." What does this prove, if it be not that the reviewer of THE LANCET, presumably well read in the specialty, and knowing my original treatise, has found nothing new in the Manual, which is but a condensed extract of the former? But could it be otherwise? And is it necessary that a book be stripped of all scientific interest, for those desiring to be placed *au courant* of a question, because it is only an extract, at least if the original work be not itself devoid of all scientific merit? Allow me to quote to you on this head the opinion of a man who is scarcely a novice in the subject: "That is," says M. Pasteur, "what I have just done with your book.....of such great general and scientific interest."

I am, Sir, yours truly,

P. WARLOMONT,
President of the Royal Academy of Medicine of Belgium.

San Remo, March 29th, 1886.

"CAN A HERNIA DISAPPEAR IN A FEW WEEKS?"

To the Editor of THE LANCET.

SIR,—The above is the title of an annotation in THE LANCET of Feb. 20th (p. 363). I am able to answer the question in the affirmative. A slowly on-coming hernia is by no means so likely to disappear, or be cured, as the one Dr. Velleman of Brussels saw; but I will vouch for the following. I copy from my note-books:—"July 27th, 1879, John D——, aged two years, was brought to me on account of a left oblique inguinal hernia. At the top of the right scrotal sac, just over the spermatic cord, is a congenital nævus, quite circular, one-eighth of an inch high and three-fourths of an inch in diameter. There is atrophy of the right testis, and hypertrophy of the left, with thickening of its cord. There is slight tenderness of the left testis. The hernia is a small one, not quite as large as a pigeon's egg, and comes only just outside the external ring. It was first noticed four weeks ago. Applied a truss." The child was brought to me next on Aug. 18th, when I noted the following:—"The tenderness of the left testis has disappeared, and the gland is softer. The truss-pad had caused some irritation of the skin, with a little inflammatory action beneath, and the hernia has completely disappeared. Making the child cry, crowding down the intestines by pressure on the abdomen, and bending his body backwards failed to force down any intestine or omentum. A weaker truss was advised to be kept applied for some time longer as a precaution." In this case the hernia disappeared in three weeks.—I am, Sir, yours truly,

P. O'CONNELL, M.D., M.Ch., Queen's Univ., Ireland.

Chicago, Ills., U.S.A., March 6th, 1886.

DRY DRESSINGS FOR INTERNAL CAVITIES.

To the Editor of THE LANCET.

SIR,—Since the publication in THE LANCET of my paper on the above subject I have had numerous correspondences from brother practitioners and chemists as to where to procure and how to make the vaginal suppositories referred to. Would you kindly allow me to state that specimens may be procured and all particulars obtained from Messrs. Clare and Hunt, chemists, Scarborough.—I am, Sir, yours truly,

Scarborough, April, 1886. CHAS. F. HUTCHINSON, M.D.

CIVILISATION AND THE SIZE OF THE HUMAN CRANIUM.

IN the course of a paper recently read before the Grant College Medical Society at Bombay by Surgeon D. N. Parakh, I.M.D., in which an account was given of the midwifery work done in the only obstetric hospital in Bombay for native women, the author remarked that from measurement soon after birth of the transverse, fronto-mental, and the antero-posterior diameter of the heads of native children the conclusion was that the greatest measurements were in the following order as to race: (1) European; (2) Persian or Iranee Parsee—i.e., a modern Persian professing the old Zoroastrian religion, and just arrived from Persia; (3) Parsee; (4) Goanese; (5) Mahommedans, Hindoos, and native Christians. From what he had seen in practice, his impression was that owing to the increasing civilisation of the masses in India the human cranium is gradually increasing in size, the pelves of women unfortunately not undergoing a corresponding increase in capacity. This is particularly the case among the Parsees, who have, under the British rule, suddenly emerged from a semi-barbarous life into a life of great mental activity, the males (even now) being about a generation or two ahead of the women in that respect. Hence British rule, whilst it has improved the head and heart and purse of the coming Parsee race, has entailed greater suffering on the parturient woman. In saying so, Mr. Parakh was not, he stated, unmindful of other evils of civilisation which make parturition difficult. The average weight of the children at birth was 5·85 lb. The maximum was 8·75 lb. The minimum 3·75 lb. The heaviest children were in precisely the same order as to race as mentioned above in the case of head measurements.

Professor Buchanan (Glasgow).—Yes, in an early number.

THE LUNACY LAWS.

To the Editor of THE LANCET.

SIR,—I feel it my duty to report the experiences I have lately had in certifying as to the mental condition of a supposed lunatic; believing it will afford assistance to many, and draw attention to a serious defect in our lunacy laws and expose a grave injustice, both to medical men and to those whom they may be called upon to examine; as a premium obviously is being offered on their being able to establish the insanity of the person.

Last November, late one evening, the relieving officer of the Brentford Union called on me, bringing a printed official order, signed by the chairman of the Brentford magistracy, commanding me to visit a very poor young girl in the neighbourhood who had been reported to him as being insane by the Poor-law official. I was also directed to send in writing by that night's post the opinion I had formed respecting her condition. I reported that although the girl exhibited many suspicious symptoms, yet I hardly felt able to certify her as being insane; but I would advise her admission into the workhouse infirmary, where she might be watched. The relieving officer, however, informed me that as she was a suspicious mental case she could not be admitted, there being no accommodation there for such patients. Accompanying my report was an application from myself for a fee of 21*s.*, to which I received no reply. I applied again with the same result. Then I wrote to Mr. Glossop, the magistrate who had signed the order, and from him I received a most kind and courteous letter, assuring me that the matter should be immediately looked into by him. In a few days he wrote again to say that he had written to the clerk of the magistrates, and he had replied that the guardians had refused to acknowledge their responsibility, and the Local Government Board and the Lunacy Commissioners had also denied assistance. Unfortunately just at this moment Mr. Glossop died; but had he lived I feel sure he would have left no stone unturned until my fee had been paid to me. Mr. Hastings Draper, solicitor, of 83, Vincent-square, kindly now took the matter up, and on last Saturday week he made an application at Brentford before the magistrate on my behalf. But the decision was given against me, the magistrates refusing to acknowledge their responsibility, and also acquitting the guardians from theirs. I was, however, directed to write to the clerk of the county board, but he referred me to Scotland-yard, and there the matter rests at present, the reply that I shall probably next receive from that quarter being quite as unsatisfactory as the others. The magistrates refused my application on the ground that although the relieving officer had applied to them for assistance, and the girl, although not in actual receipt of Poor-law relief, was nevertheless virtually a pauper, the guardians could not be made responsible, because she was not on the books as a pauper; and also for the astounding reason that I was unable to establish her insanity. Therefore it would appear that if she had been a pauper and not lunatic, or if she had been a lunatic and not a pauper, or if she had been a lunatic possessed of property and at large, or if she had possessed means and I had failed to establish her insanity, I had no claim on the magistrates or guardians, even though I had been in each instance ordered by the magistrates to attend. I think I need add little to what I have written in order to show what a great injustice exists both towards the medical practitioner and the unfortunate individuals he may be called upon to examine, but I do not believe you will deem that I have trespassed unnecessarily on your space in endeavouring to urge that immediate steps should be taken to rectify so great an evil.

I am, Sir, your obedient servant,

Ealing-common, April 5th, 1886. W. C. STEELE.

MICRO-ORGANISM OF CARCINOMA.

To the Editor of THE LANCET.

SIR,—On Saturday last I received from Dr. Andrew of Shrewsbury a breast containing a hard lump, which on section proved to be a typical scirrhus." As the specimen was quite fresh, and had not been in any kind of hardening fluid, or, indeed, been cut into or examined in any way, I thought it a good opportunity for ascertaining the presence or absence of micro-organisms. I therefore dried the surface of the growth with filter paper, and made a cut through the centre of the tumour with a clean knife. I then scraped the cut surface, and moistened a series of cover glasses with the "cancer juice." The films, being dried, were stained with gentian violet, methyl blue, &c. At first I was not able to see any organisms, though the large nucleated cells of the alveoli were deeply stained. But in one or two preparations which had been longer in the staining fluid I was surprised to find the field entirely covered with enormous numbers of micrococci. They were but faintly coloured, yet were distinctly visible with a $\frac{1}{12}$th immersion objective. "Juice" from various parts of the tumour was examined, with the same result. Sections were then cut with the freezing microtome, and stained, with a view to demonstrate the distribution of the micrococci in the tissue elements. But though many dyes were used, and the sections, in some attempts, left many hours in the fluids, the micro-organisms were in most cases not stained at all; so that in one or two only, with very careful illumination, could the organisms be seen. From what was then made out, they seemed to abound chiefly in the spaces between the cells of the alveoli. They were also seen within the protoplasm of the cells. The fibres of the connective tissue were in places covered with them. They were much fewer in number beyond the growing margin of the tumour.

I am hoping that these observations will lead to the examination of many more carcinomata, and that a stain may be found which will colour these micrococci with certainty, even when *in situ* in thin sections of the morbid growth. I am, Sir, yours faithfully,

Iron Bridge, March 29th, 1886. LAW WEBB.

Ignoramus.—The term is one not recognised in medicine, and is probably intended to denote the peculiar tint of the expectoration.

HOSPITAL NURSES.

To the Editor of THE LANCET.

SIR,—I wish to appeal to you on behalf of the health of hospital nurses. Many nurses break down, and their health is permanently undermined, by their being kept on duty until they are laid up by serious illness, which illness might be prevented, or rendered much less serious, by a little relief from duty and proper medical treatment in the early stages. In most hospitals the matron has the entire control of the nurses; she engages and discharges them, and they are not allowed to speak to one of the medical officers without first obtaining her permission. Consequently, a nurse will never complain to the matron of not being well until she is really seriously ill, for fear the matron might think she was either shirking work or not strong enough for her duties, and so discharge her at once. A frequent cause of ill health is unsuitable and insufficient food, with too little time to take it. For example, at one of the smaller but most popular metropolitan hospitals breakfast, consisting of tea and bread-and-butter only, is served at 6.30 A.M., and only a quarter of an hour is allowed to take it. After this somewhat scanty and hurried meal, the nurse has to be on duty in the wards for five hours and a quarter before she gets her dinner. Cannot something be done to improve this? The patients have their medical officers and the house visitor to supervise the supplying of their wants, and to whom they can appeal. Could not the same excellent supervision be extended to the nurses' home? Apologising for troubling you,

I am, Sir, yours faithfully,

A WHILOM HOSPITAL NURSE.

Hednesford, Staffordshire, April 6th, 1886.

COLOUR-BLINDNESS AMONG MEDICAL MEN; "ANOSPHRESIA"; PARTIAL ANOSMIA AND HYPHROSMIA.

To the Editor of THE LANCET.

SIR,—I am indebted to Mr. St. Clair Buxton for his reply to my inquiry. I, of course, purposely avoided the question of any means of diagnosis other than vision. Truly enough, not all of us get called as witnesses as to fact; but medical practitioners are, I think, more liable to be called than the average run of men. It would seem advisable for all persons, particularly medical men, to have their vision tested for colour, and, if defective, to keep a detailed record of the facts. That might be useful, among other things, for a determination of the amount of change, if any, occurring with the lapse of years. I am greatly interested in Dr. Nicholas' "anosphresia." I think that there is no doubt about its existence, and I shall look forward with pleasure to the expression of any opinions with which Dr. Stevenson may favour us. Certainly, a partial anosmia—which I take to mean complete inability to smell one or a few odours—exists, as does a partial hyperosmia, an exceedingly acute power of smell for one or several odours, the powers of smell for all other odours being an average or "normal" one. This is one of the topics I have discussed in my little work mainly on "olfactics," which is now in the press.—I am, Sir, yours faithfully,

CHAS. H. PIESSE, M.R.C.S., F.I.C.,

Strand, W.C., April 1st, 1886. Public Analyst.

A SEA-VOYAGE AND AUSTRALIA FOR PHTHISIS.

To the Editor of THE LANCET.

SIR,—For the benefit of the profession generally, and particularly for those medical men who are so fond of sending away their phthisical patients to Australia as a last resort, a few suggestions may not be out of place.

I have just arrived, having come out in a ship in which, without exaggeration, there were quite 85 per cent. of invalids among the passengers, and those chiefly consumptive. From my own observations, I noticed that those in the first stage invariably recover, and if the journey does not cure them, a subsequent residence in Australia usually does. Those in the second stage sometimes benefit by the voyage, or, on the other hand, may go back; whilst those in the third stage nearly always succumb—I believe it is very rarely that they recover. Now, it is particularly respecting this last class that I venture to address you. As recovery is so rare, does it not seem a great shame to take these patients away from a good home with all its attendant comforts and kind friends to rough it by themselves at sea? And, I assure you, there is a very great deal to put up with, though it would be occupying too much of your valuable space to go into details. Then I would earnestly recommend the medical men in England to give it their utmost consideration before deciding to send a patient away in this stage. I do not think I am alone in these opinions. I believe they will be fully endorsed by those who have been to sea under similar circumstances. And now, as to the time of the year a patient should be sent out. Really, that does not matter; as soon as it is found that a patient is ill with phthisis, the sooner he sets out the better. At no time is the winter here so severe as at home, and in this neighbourhood it is particularly genial. The nights and mornings are frosty, but the days warm. The air is invariably very dry. In the summer, however, it is very hot, and a somewhat mountainous district should be chosen. Most of the Melbourne practitioners send their patients in the winter to Sandhurst, Echuca, or the Riverina.

Hoping these few remarks may be of some little use to medical men in England, Believe me, Sir, yours faithfully,

Sandhurst, Victoria. M.R.C.S.

THE COMMISSION ON HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—I am sorry to trespass on your limited space; but I quite agree with your correspondent, Mr. Moore, M.R.C.V.S. (p. 670), and cannot imagine why the name of the eminent veterinary surgeon, Mr. G. Fleming, should not have been placed on that Commission, or his name even mooted in connexion with it, which appears so conspicuous by its absence. Is it still in its embryonic state, or has a committee been formed, and an order promulgated to that effect, composed of those members of the profession whose names appeared a short time ago? If such is the case, I cannot but think a grave error has been committed by those responsible for such a board concerning the valuable information that might have accrued from such an authority on rabies canina. The very backbone or information we require lies here, and yet they do not place a representative of that profession on the list. For the sake o suffering humanity and the feelings of those medical men who have the misfortune to be brought into contact with that terrible malady, I think it but fair that every available source should be seized, and such would be greatly enhanced by placing Mr. Fleming on the list, by virtue of his position, and by so nobly heading that profession to which he belongs.

I have the honour to be, Sir, your obedient servant,

City London Infirmary, E., April, 1886. W. GEM.

L.R.C.P. — Parkes' Hygiene, Ganot's Physics, Baldwin-Latham's Sanitary Engineering, and the Public Health Acts. A practical knowledge of chemistry and microscopical analysis of water is required, as well as of the manner in which a sanitary report should be written.

A QUESTIONABLE TREAT.

To the Editor of THE LANCET.

SIR,—On the occasion of the Oxford and Cambridge Boat Race on Saturday last two friends and I, by virtue of cards of invitation from the local authority, were admitted to the (sewage) pumping station at Corney, Chiswick to view the race, where we stayed some two hours. But during the whole time a most sickening odour prevailed. Was the authority justified in converting such a spot, with its tainted atmosphere, into a pleasure resort? There were hundreds of men, women, and children present. The works may satisfy the Thames conservators; but was not the purpose that it was put to on Saturday last liable to be injurious to health? I am, Sir, your obedient servant,

April 7th, 1886. W. W.

RINGWORM IN A NEW-BORN INFANT.

To the Editor of THE LANCET.

SIR,—A lady who for some time past has had a dread of ringworm appearing in any of her children was delivered about a month ago of a female child, which was found to have several spots of ringworm on its body and one on the scalp. These have gone on increasing, and now rather an extensive surface of the back is covered with the rings. Is it not unusual for this affection to appear in a child of that age? I should like some of your readers to say what treatment they would recommend under the circumstances (age of child and extent of surface affected).

I am, Sir, yours truly,

March 30th, 188 SURGEON.

AN UNUSUAL CASE OF CONGENITAL MALFORMATION.

To the Editor of THE LANCET.

SIR,—Perhaps you may consider the following case of sufficient interest to find a place in your columns.

On Jan. 28th I was summoned to the house of Mrs. P——, who gave birth to her eighth child at 1 P.M. on the previous day. The midwife in attendance complained that the child was sick each time it took milk-and-water, but that the food did not appear to reach the stomach. On examination, I found the child (a girl) healthy looking and well developed, and the mouth and fauces normal. Meconium and urine had passed several times. I left, promising to return in the evening, ordering a little weak milk-and-water to be administered at intervals during my absence. Hearing on my return that nothing had been retained in the child's stomach, I ordered some nourishment to be administered in my presence, so that I might watch the result. A few spoonfuls were taken, but the liquid was quickly returned unaltered. Thinking there must be some obstruction in the œsophagus, I explored this region with a No. 8 French coudée catheter, but the instrument was arrested at a point on a level with the upper border of the sternum. I tried one or two smaller sizes, with the same result, and came to the conclusion that the œsophagus was impervious at the point named. The child, after becoming very much emaciated, died at 2 A.M. on Feb. 2nd, the ejection of nourishment continuing until death. I think, apart from the abnormal condition of the œsophagus, the case is of some interest on account of the time the child existed without food, the character of the motions, which were passed daily until the day before death, indicating that nothing in the shape of milk had entered the stomach. I regret that the parents would not allow a post-mortem examination to be made.

I am, Sir, yours faithfully,

GEORGE HERBERT SALTER, M.R.C.S., &c.

Gisborne, Victoria, Australia, Feb. 2nd, 1886.

Mr. W. Wallace had better apply at the Office of the Crown Agents for the Colonies, Downing-street, S.W.

CASE OF DISTENDED BLADDER WITHOUT SYMPTOMS.

To the Editor of THE LANCET.

SIR,—The following case may perhaps be deemed worthy of record in your columns.

The Rev. M——, aged seventy, was first seen in September, 1885, for eczema. I discovered on examining his abdomen an oval tumour, which reached up to the umbilicus. This continued increasing in size until the middle of March, 1886, when I again saw him. The tumour had now grown above the umbilicus, and there was a slight bulging of it towards the left. He did not pass urine more than twice or thrice a day, and only once during the night, "to break the monotony," as he said. His urine was free from mucus or pus. Whilst under the influence of chloroform, Mr. F. Treves drew off three pints and twelve ounces of perfectly healthy urine, the tumour entirely disappearing. An examination per rectum revealed a large middle lobe of the prostate, and some enlargement of the right lobe.

I venture to bring this case forward in a very brief manner to demonstrate the occurrence of a bladder distended with nearly four pints of urine, and not causing any symptoms which gave rise to a suspicion of its presence.

I am, Sir, yours faithfully,

Princes-street, W., April, 1886. T. ROBINSON.

"APOPLEXY WITH COMPLETE HEMIPLEGIA."

To the Editor of THE LANCET.

SIR,—With reference to his most interesting case of hemiplegia in a patient aged twenty-five, which appeared in THE LANCET of March 20th, p. 568, Dr. Fraser asks, "Is it sanguineous or serous effusion or hysteria?" I should say neither, but probably embolism. It would be interesting to know if the anæmic (?) murmur still exists.—Yours faithfully,

Pill, Somerset, April 2nd, 1886. A. H. BOYS.

Croonian Lectures

ON

SOME POINTS IN THE PATHOLOGY OF RHEUMATISM, GOUT, AND DIABETES.

Delivered at the Royal College of Physicians of London, April, 1886.

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

LECTURE II.

(*Concluded from page 677.*)

Two years ago I published a paper on the formation of uric acid, in which I endeavoured to show that the formation of this substance in the human subject is due, in the first place, to defective assimilation or metabolism, and, secondly, that it is a condensation product much in the same way that cyanuric acid is a condensation product of cyanic acid or that cyanuric acid and biuret are condensation products of urea. Starting with the result obtained by Strecker,[1] that if uric acid is heated in a sealed tube to 160°–170° C. with a cold saturated solution of hydriodic acid, it is decomposed with the formation of ammonium iodide, carbonic acid, and glycocine:

$$\underset{\text{uric acid}}{C_5H_4N_4O_3} + 5H_2O = 3NH_3 + 3CO_2 + \underset{\text{glycocine}}{CH_2(NH_2)COOH},$$

I endeavoured by treating glycocine in sealed tubes and otherwise with cyanuric acid and potassium cyanate to reverse the process and perform the synthesis of uric acid, but unsuccessfully. Horbaczewski, however, stated in a paper published in the *Berichte* for Nov., 1882, page 2678, that by heating glycocine and urea together he had accomplished it. On heating glycocine with ten times its weight of urea in an open vessel to 200°–230° C. he obtained a cloudy and thick fluid. This, on cooling, was dissolved in weak potash solution and supersaturated with ammonium chloride and precipitated with an ammoniacal solution of silver and magnesia. This precipitate containing the uric acid was washed with water containing ammonia and decomposed with potassium sulphide. The filtrate freed from the precipitate was supersaturated with hydrochloric acid and evaporated down. On cooling the impure uric acid separated, which was again dissolved in a weak solution of potash, and submitted twice to the same process as above. Lastly, the product was washed with alcohol and dried. It was next treated with bisulphide of carbon to dissolve the sulphur, and then treated with ether. I tried the experiment, carefully following the directions, but failed to obtain a satisfactory result. Testing the substance at various stages, I got with nitric acid and ammonia a colour somewhat approaching the murexide colour, but nothing more. I failed then probably from using too high a temperature. The experiment for a long time received no confirmation, but in May, 1885, in the *Monats. f. Chemie*, S. 356–362, Horbaczewski gives the following additional particulars:—

"Uric acid is obtained very readily by carefully heating a mixture of glycocoll and urea in a test-tube over the flame of a small Bunsen's burner, holding the test-tube in an inclined position and moving it backwards and forwards over the flame, and taking care to keep up a continuous and free evolution of ammonia from the mass, being careful also that the temperature is not raised too high. The mass, at first clear and colourless, gradually becomes yellowish and opaque. The mass is then heated very carefully until (during the heating) it becomes quite hard, without being charred, or at least until a copious deposit is formed. The experiment is now completed. It is desirable to use only a small quantity (0·1 grm. to 0·2 grm.) of glycocoll at one time. In this way the whole experiment occupies only a few seconds, and the residue after cooling remains of a pale yellowish colour; while by using a large quantity of glycocoll the residue appears of a dark brown colour. As regards the quantity of urea which must be used in the process, it is necessary to use a large excess. When, therefore, the glycocoll and urea are mixed together in proportion of one molecule of each, no uric acid is obtained, nor is any obtained when one molecule of glycocoll is taken with two molecules of urea. It is only when three molecules of urea are taken with one of glycocoll that uric acid is produced. It is very difficult, however, to isolate the uric acid in this case, and to purify it, on account of the very dark brown colour of the residue. The larger the quantity of urea taken, the more easily is the experiment made, and the residue is so much freer from colour. It is therefore advisable to mix one part of glycocoll with from seven to fifteen of urea, and to heat them together in the manner above described. If the experiment is successful, a very small portion of the residue gives the murexide reaction; it is not so marked as with pure uric acid, but it is quite distinct. If the experiment has not been perfectly carried out, no murexide reaction will be obtained from the residue alone. The amount of uric acid obtained by this method, even when successfully performed, is rather small. In several experiments from one gramme of glycocoll and the proportionate quantity of urea, only from 50 to 150 milligrammes of impure uric acid were obtained. The reason of this unsatisfactory result appears to be that the reaction only takes place at a high temperature, at which also the uric acid is in some measure decomposed."

After reading this paper I again tried the experiment, and succeeded in producing the substance. [The full details of the process will be found in THE LANCET for Feb. 6th, 1886, page 244. Several specimens obtained by this method were exhibited at the lecture.]

The following equation represents the changes:

$$3CO\begin{cases}NH_2\\NH_2\end{cases}_{\text{urea}} + CH_2\begin{cases}NH_2\\COOH\end{cases}_{\text{glycocine}} = 3NH_3 + 2H_2O + \underset{\text{uric acid}}{C_5H_4N_4O_3}$$

But it is important to know what are the intermediate stages, if we are to understand the mode of formation of this substance in the living body. Now hydantoic acid has been formed synthetically, and here we have the first step towards the synthesis of uric acid. By heating urea and glycocine to a temperature of 120°–125° C. they combine and form hydantoic acid:[2]

$$CO\begin{cases}NH_2\\NH_2\end{cases}_{\text{urea}} + CH_2\begin{cases}NH_2\\COOH\end{cases}_{\text{glycocine}} = NH_3 + CO\begin{cases}NH_2\\NH-CH_2-COOH\end{cases}_{\text{hydantoic acid}}$$

and this dehydrated forms hydantoin; for by boiling the latter with baryta water it is converted into hydantoic acid:

$$CO\begin{cases}NH-CO\\|\\NH-CH_2\end{cases}_{\text{hydantoin}} + H_2O = CO\begin{cases}NH_2\\NH-CH_2-COOH\end{cases}_{\text{hydantoic acid}}$$

By heating urea alone to a temperature somewhat higher—viz., to 150°–160° C.,—condensation takes place and it is converted into biuret, $C_2O_2N_3H_5$.

$$2CO\begin{cases}NH_2\\NH_2\end{cases}_{\text{urea}} = NH_3 + \underset{\text{biuret}}{CO\begin{cases}NH_2\\NH\\NH_2\end{cases}}$$

If now we combine together hydantoin and biuret, we have the elements of water and ammonium urate:

$$CO\begin{cases}NH-CO\\|\\NH-CH_2\end{cases}_{\text{hydantoin}} + CO\begin{cases}NH_2\\NH\\NH_2\end{cases}_{\text{biuret}} = H_2O + \underset{\text{ammonium urate}}{C_5H_3N_4O_3 \cdot NH_4}$$

In performing Horbaczewski's experiment, when the temperature is raised to 120°–125° C. hydantoic acid is formed, and at 150°–160° C. the urea condenses into biuret. If, then, between 130° and 160° C. the hydantoic acid is dehydrated into hydantoin, which melts at 207°, and at that temperature or one something above, combined with the biuret in

[1] Strecker, Zeitschrift f. Chem. [2], iv., 215.

[2] Heintz: Jahresb. für Chem., 1865, s. 360.

Digitized by Google

the manner above shown, forming water and ammonium urate, we have a complete explanation of the process. That the synthesis takes place in this way I have confirmed in some measure by experiment. One part of hydantoin with four parts of biuret were treated in the same manner as in the experiment with urea and glycocine. Throughout the same results follow as when operating upon glycocine and urea, but the yield of uric acid is smaller. On evaporating the solution after the addition of hydrochloric acid, crystals are deposited which give the murexide reaction very distinctly, but as yet I have not been able to isolate the uric acid.[3] The constitution of glycoluril $C_4H_6N_4O_2$, which can be obtained from uric acid and from allantoin, also favours this view. By boiling glycoluril with acids it is converted into hydantoin and urea, consequently by combining these substances together in a suitable way we ought to perform the synthesis of glycoluril:

$$CO\begin{cases}NH-CH_2\\ \quad|\\ NH-CO\end{cases}_{\text{hydantoin}} + CO\begin{cases}NH_2\\ NH_2\end{cases}_{\text{urea}} = CO\begin{cases}NH-CH\\ \quad\|\\ NH-C-NH-CO-NH_2\end{cases}_{\text{glycoluril}} + H_2O$$

If, then, hydantoin were combined with biuret instead of urea, we should have

$$CO\begin{cases}NH-CH_2\\ \quad|\\ NH-CO\end{cases}_{\text{hydantoin}} + CO\begin{cases}NH_2\\ NH\\ NH_2\end{cases}_{\text{biuret}}$$

$$= CO\begin{cases}NH-CH\\ \quad\|\\ NH-C-NH-CO-NH-CO-NH_2\end{cases} + H_2O$$

and ammonia being given off, the compound would be

$$CO\begin{cases}CO-NH\\ \quad|\\ NH-C\quad CO\\ \quad\|\quad\ |\\ NH-C-NH\end{cases}_{\text{uric acid}} + NH_3 + HO_2$$

which is the molecular formula for uric acid given by Medicus, and the one most generally accepted.[5]

My explanation of the formation of uric acid in the animal economy, based on these considerations, is as follows. In the human subject glycocine conjugated with cholic acid is poured out as glycocholic acid, a constituent of the bile, into the intestine. After the bile has served its purpose in digestion, the glycocine as well as taurine are returned into the blood. These, together with the other amido bodies, leucine, and possibly tyrosine, the products of the digestion of albuminous food, reappear in the urine as urea; that is, the urine does not contain them, but its urea is proportionately increased. Now these amido bodies, glycocine, leucine, &c., are probably carried by the portal vein straight to the liver, and from certain facts which I need not here detail we are led to the view that among the numerous metabolic events which occur in the hepatic cells, the formation of urea from these bodies may be ranked as one. Suppose from some cause this metabolism of glycocine is interrupted (and I need only refer here to the interrupted metabolism of starch or glucose in diabetes as an illustration of what I mean), whilst taurine, leucine, &c., still undergo the normal changes with the production of urea, we should then have in the gland the two substances, glycocine and urea (or the immediate antecedent of urea), the conjugation of which by the gland (just as in the case of hippuric acid being formed from the conjugation of glycocine and benzoic acid) would produce hydantoic acid:

$$CO\begin{cases}NH_2\\ NH_2\end{cases}_{\text{urea}} + CH_2\begin{cases}NH_2\\ COOH\end{cases}_{\text{glycocine}} = NH_3 + CO\begin{cases}NH_2\\ NH-CH_2-COOH\end{cases}_{\text{hydantoic acid}}$$
(ammonia)

which dehydrated would be converted into hydantoin

$$CO\begin{cases}NH-CO\\ \quad|\\ NH-CH_2\end{cases}$$

Hydantoin is easily soluble, and so would pass on in the circulation to be combined elsewhere with two molecules of urea or with biuret, which is also soluble, to form ammonium urate:[6]

$$CO\begin{cases}NH-CO\\ \quad|\\ NH-CH_2\end{cases}_{\text{hydantoin}} + CO\begin{cases}NH_2\\ NH\\ NH_2\end{cases}_{\text{biuret}} = H_2O + C_5H_8N_6O_3 \cdot NH_4$$
(ammonium urate)

It may be urged as an objection that in order to produce hydantoic acid and biuret out of the body a temperature of 160° C. is required, and therefore that the body at the normal temperature of 37°–38° C. cannot produce this result. The fact that the conjugation of benzoic acid and glycocine takes place in the body at the normal temperature when benzoic acid is introduced into the alimentary canal, hippuric acid being formed and passing off in the urine, to effect which conjugation out of the body requires exactly the same temperature of 160° C., is a complete answer to such an argument. But I will show directly that the combination of urea, or its antecedent ammonium cyanate, with other bodies does actually take place in the animal body.

Horbaczewski, in his paper in the *Monatshefte*, also describes a method for obtaining methyl uric acid by synthesis. He says: "It was naturally to be expected that if in the previous experiment instead of glycocoll a derivative of glycocoll was employed, instead of uric acid a derivative of uric acid would be obtained. The experiment was performed with sarcosine, and confirmed this supposition. When sarcosine is heated in small portions (0·1 to 0·2 grm.) with five to ten parts of urea, after the method described for uric acid, and carefully warmed until the mass becomes solidified whilst hot—which can always be effected in the present case,—the residue is found to contain methyl uric acid. This can be demonstrated at once in the residue by the murexide test—in fact, a small atom generally gives a much more decided reaction than can be obtained from the uric acid residue. If the experiment has been successful, the reaction is very striking. The methyl uric acid can be separated from the residue in exactly the same way as described for uric acid. The purification of this compound can be effected far more easily than that of uric acid, and presents no difficulties whatever."

The changes which have taken place here are, I venture to suggest, of the same character as those indicated for the formation of uric acid. The sarcosine is combined first with

---

[3] The reason probably is that the hydantoin combines more readily with the biuret in its nascent state—that is, as condensation of urea takes place—than with biuret fully formed.

[4] Strecker-Wislicenus: Org. Chemistry, London, 1881, p. 539.

[5] This explanation of the synthesis of uric acid indicates, I think, the way in which guanine, xanthine, hypoxanthine, theobromine, and caffeine may each be built up from glycocine, and thus showing their relationship to uric acid. By combining glycocine with formyl diamine

$$CH\begin{cases}NH_2\\ \diagdown\\ NH\end{cases}$$

which is prepared from HCN, we should obtain the substance

$$CH\begin{cases}NH-CH_2\\ \diagdown\quad|\\ N-CO\end{cases}$$

and this, united with two molecules of urea, or with biuret, would probably result in

$$CH\begin{cases}CO-NH\\ \diagdown\quad|\\ NH-C\quad CO\\ \quad\|\quad\ |\\ N-C-NH\end{cases}$$

guanine.

From guanine the other bodies have been obtained; but it would appear probable that they should be synthesised independently. By combining glycocine, formyl diamine, guanidine (obtained from biuret), and urea, in the order given, xanthine would result. By acting on the compound of glycocyne and formyl diamine so as to obtain its methyl derivative

$$CH\begin{cases}N\cdot CH_3-CH_2\\ \diagdown\quad|\\ N\text{———}CO\end{cases}$$

combining this with dimethyl carbamide, and then with urea, the resulting product should be caffeine. I have not had time to attempt these experiments since this mode of synthesis occurred to me. I hope to do so, however, during the summer, and so either confirm or refute the hypothesis.

[6] In the paper published two years ago I suggested that the synthesis might take place also, in another way, by the conjugation of glycocine first with biuret, which afterwards combining with urea would form ammonium urate; but this would give a different molecular arrangement for uric acid, and the actual production of uric acid from hydantoin and biuret shows that this is the correct interpretation.

Digitized by Google

one molecule of urea forming methyl hydantoic acid, which dehydrated into methyl hydantoin and then combined with biuret forms ammonium urate:

$$CH_2\begin{cases}NH.CH_3\\COOH\end{cases}\ (\text{sarcosine}) + CO\begin{cases}NH_2\\NH_2\end{cases}\ (\text{urea}) = NH_3 + CO\begin{cases}NH_2\\N.CH_3-CH_2.COOH\end{cases}\ (\text{methyl hydantoic acid})$$

$$CO\begin{cases}NH_2\\N.CH_3-CH_2-COOH\end{cases}\ (\text{methyl hydantoic acid}) = CO\begin{cases}NH\text{——}CO\\N.CH_3-CH_2\end{cases}\ (\text{methyl hydantoin}) + H_2O$$

$$CO\begin{cases}N.CH_3-CH_2\\NH\text{——}CO\end{cases}\ (\text{methyl hydantoin}) + CO\begin{cases}NH_2\\NH\\NH_2\end{cases}\ (\text{biuret})$$

$$= CO\begin{cases}N.CH_3-C & CO-NH\\ \| & |\\ NH\text{——}C-NH & CO\end{cases} + NH_3 + H_2O\ (\text{methyl uric acid})$$

Now methyl hydantoin has been actually formed after the administration of sarcosine to a living animal and detected in the urine. Considerable discussion took place at the time this was announced as to whether or not methyl hydantoin really appeared in the urine, and a number of experiments were made by Schultzen, &c. The importance attached to the question at the time arose from the fact that it appeared to demonstrate the existence of carbamic acid in the animal system, and to show that this acid was the immediate precursor of urea. A good deal may be advanced in favour of this view of the formation of urea, but as I have endeavoured to show that the antecedent of urea is ammonium cyanate, and as methyl hydantoin has been formed by mixing together sarcosine, potassium cyanate and ammonium sulphate, and digesting them at the temperature of the body (40° C.), the experiment with sarcosine possesses great interest and significance with regard to the steps by which uric acid is formed in the animal economy. In the *Zeitschrift für physiologische Chemie* Dr. J. Schiffer gives an excellent summary of the experiments and views of the others, together with an account of his own observations and experiments. From this paper[7] I take the following extracts:—

"Few investigations in the range of physiological chemistry have in recent times excited so much attention as those of Schultzen on the transformation of sarcosine in the animal body. In conjunction with Leon v. Nenki[8] he had previously found, on giving glycocine as food, the amount of urea excreted corresponded with the amount of N given. ..... He repeated his experiments with methyl glycocine, or sarcosine. Increased secretion of urea did not take place; on the contrary, two new bodies appeared in the urine, both having an analogous composition, the one compounded of sarcosine and carbamic acid, the other of sarcosine and sulphamic acid. The first of these bodies was identical in its constitution with methyl hydantoic acid, but was not recognised as such by Schultzen. He concluded from his investigation that the sarcosine attached to itself the carbamic acid resulting from disintegration of the albuminous bodies, and which in a normal condition gives rise to the production of urea. With this hypothesis it appeared very plausible that urea should disappear from urine containing sarcosine. He imagined, therefore, he had explained the mode in which urea was formed, and had thus solved one of the most important questions in physiological chemistry by the convincing proof of a carefully devised experiment. ..... Salowski found, after administering taurine, its uramido-acid tauro-carbamic acid in the urine.[9] ..... Later E. Bauman and Hoppe-Seyler[10] succeeded in forming methyl hydantoic acid synthetically under such conditions as might exist in the animal body. Equivalent amounts of sarcosine, potassium cyanate, and ammonium sulphate were digested at a temperature of 104° F., the potassium sulphate removed by alcohol, and the baryta salt of the acid referred to obtained. In a similar manner Salkowski[11] at the same time produced this acid, or rather, as it is easily decomposed, its anhydride, methyl hydantoin. So far everything seemed to confirm Schultzen's experiments. But when further experiments were made, essentially different results were obtained. These experiments were undertaken by E. Salkowski on the one hand, and Bauman and v. Mering on the other. The results obtained by all completely demonstrate the absence of sarcosine sulphamic acid. As regards methyl hydantoic acid, Salkowski[12] first stated that in the urine of dogs it appeared only in small quantity after the administration of sarcosine; whereas Bauman and v. Mering, in their experiments on the human subject, showed that after administering as much as 25 grammes of sarcosine, methyl hydantoic acid was entirely absent from the urine, and that Schultzen in his experiments could not have had this substance to deal with. At the same time they discovered a probable source of error in his experiments—viz., that in the presence of sarcosine Liebig's test for urea fails. They discovered also, as Salkowski also did, that a portion of the sarcosine appeared unchanged in the urine. In later communications Salkowski confirmed the view of Bauman and v. Mering, that after the administration of sarcosine there is no appearance whatever of methyl hydantoic acid in the urine. There appeared to be very little left, then, from Schultzen's experiments. One point only still remained for investigation. As the uramido-acids are so easily converted into their anhydrides, and as this is specially so in the case of methyl hydantoic acid and its conversion into methyl hydantoin, this latter substance might possibly exist in the urine after the internal administration of sarcosine. Salkowski has given great care and attention to this point, without, however, arriving at any definite proof. ..... This, then, was the state of the question when Professor Bauman informed me that methyl hydantoin reduces sulphate of copper in an alkaline solution, and asked me to make some fresh experiments with sarcosine founded upon this reaction." Schiffer then describes the experiments he performed to demonstrate the existence of methyl hydantoin in the urine, and thus sums up the result of his investigations:—"Our knowledge therefore of the destination of sarcosine in the organism may be formulated as follows: By far the greatest part is excreted unchanged: a smaller portion, one-fifth to one-sixth, is transformed into the uramido-acid we have been discussing, or rather into its anhydride (methyl hydantoin), and a smaller portion is oxidised into methyl urea."

Sarcosine, then, undergoes little change in passing through the system, but a portion is converted into methyl hydantoin. If, therefore, when glycocine is absorbed from the alimentary canal, it does not undergo the normal change, we may reasonably suppose that when brought in contact with ammonium cyanate it will be acted upon in the same way as sarcosine and a portion transformed into hydantoin, and thus we have the first step towards the formation of uric acid. Circulating in the system, the hydantoin may, under certain conditions, so affect the central nervous system, and thereby the metabolism in the kidneys, that when it arrives at these organs condensation of two molecules of ammonium cyanate may take place with elimination of ammonia, forming biuret, and this be conjugated with hydantoin; or this condensation may take place independently of the nervous system. Condensation of the cyanates readily takes place, as is shown by the action of acetic acid on potassium cyanate, forming potassium cyanurate and potassium acetate:

$$3KCNO + 2CH_3.COOH = KH_2C_3N_3O_3 + 2CH_3COOK + 2H_2O$$

pot. cyanate — acetic acid — pot. cyanurate — pot. acetate

Such a view, I think, meets all the difficulties which have been raised with regard to previous theories as to the formation of uric acid—difficulties which have been very clearly set forth by Dr. Garrod in his Lumleian lectures. Nor is it difficult to understand that, if, as I have endeavoured to prove, the final conjugation of two soluble bodies takes place in the kidney, forming the very slightly soluble ammonium urate 1-1 2400, a portion may not be excreted but remain in the blood, overflow as it were, and so pass on into the circulation; a result which certainly happens when the ureters are ligatured. The ammonium salt would then, meeting with the soda in the blood, be converted into sodium urate, the form in which it is deposited about gouty joints. The appearance, then, of uric acid in the secretion is the result

primarily of the non-transformation or metabolism of glycocine into urea, whether that glycocine be derived from the bile poured out into the duodenum or formed elsewhere in the body.

I now come to the question of the abnormal formation of uric acid in the human system. Just as in diabetes the essential fault lies in the inability of the system, either in the liver, or it may be elsewhere, to effect the metabolism of glucose, which then passes into the circulation and is discharged by the kidneys, so in gout or gravel the imperfect metabolism of glycocine is the primary and essential defect. Unchanged, it passes from the alimentary canal or elsewhere into the liver; there, under the action of the gland, it is conjugated with urea resulting from the metabolism of the other amido bodies, leucine, &c., and is converted into hydantoin; it then passes on to the kidneys to be combined with other molecules of urea or biuret, forming ammonium urate, a portion of which overflows into the circulation and is converted into sodium urate. It is not difficult to understand that in persons who are addicted to the pleasures of the table, who are fond of port, and who take little exercise, the liver should become "sluggish," that the gland cells should from overwork become inactive or destroyed, or that the terminations of the nerves should from excessive stimulus become somewhat paralysed, and the gland in some measure, like the submaxillary after the injection of atropine. The result would be the imperfect performance of its function and the non-metabolism of glycocine. But it is not every toper and gourmand who develops gout, nor is every gouty man necessarily a toper or gourmand. Further, it is certain that uric acid is also present in excess in the blood under other pathological conditions which have no connexion whatever with arthritic mischief. How are these facts to be explained?

Gulstonian Lectures

ON

SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

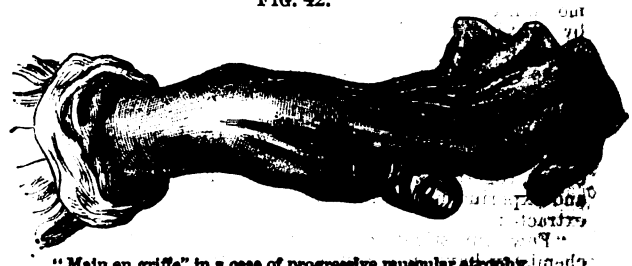
BY SEYMOUR J. SHARKEY, M.B., F.R.C.P.,

ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—In my second lecture I finished the remarks which I had to make on the connexion between the cerebral system of fibres and the clinical phenomena of spasm. I shall now proceed to a short consideration of the spinal system, and the relation between diseases which affect it and spasmodic contraction of muscles.

II. SPASM IN CONNEXION WITH SPINAL MOTOR MECHANISMS.



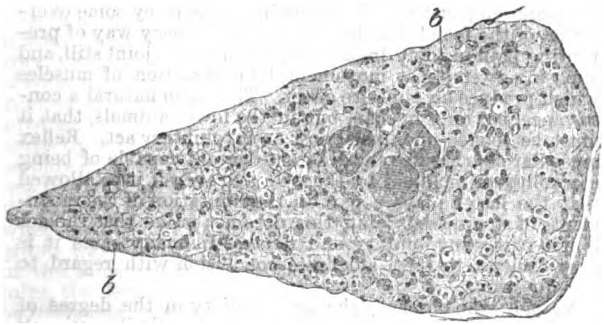
By the spinal system, I mean all those nerve-centres which occur between the central ganglia of the brain and the termination of the spinal cord. Each of these centres consists of afferent and efferent nerves and ganglionic cells; and as my object is to treat the subject from a general point of view, we may divide it into: 1. Spasm produced by diseases of efferent spinal nerves. 2. Spasm produced in a reflex manner by diseases of afferent nerves. 3. Spasm produced by diseases of the ganglionic cells.

1. *Spasm produced by Diseases of Efferent Spinal Nerves.*—A very large proportion of the cases in which spasm of muscles produces distortion are not to be explained by supposing that irritation of the diseased nerve gives rise to excessive muscular contraction. On the contrary, the healthy muscles are those actively concerned, while the diseased muscles are for the most part passive. Progressive muscular atrophy is a well-known instance of this, where a peculiar claw-like distortion is produced by atrophy of the interossei and the continued activity of other muscles (Fig. 42). Here the neuro-muscular disease appears to owe its origin to an affection of the large cells in the anterior cornua of the spinal cord. But even where no gross disease of nerve or muscle exists, it seems to be a rule that, when the origin and insertion of a muscle remain approximated for a certain time, the muscle contracts and gradually shortens. This frequently occurs in joint disease, and after prolonged application of splints. In the case of progressive muscular atrophy, the "claw" condition results mainly from atrophy of the interossei. These muscles extend the two distal phalanges and flex the proximal, and when their influence is removed the opposite condition prevails, owing to the action of opponents—namely, extension or hyper-extension of the proximal phalanges, and flexion of the peripheral. The case from which the drawing was taken was kindly sent me by Mr. Sidney Harvey. The patient was a woman aged twenty-seven, who was healthy in other respects, and the mother of a family. The disease had commenced in the left hand at the age of seventeen or eighteen.

Another instance of a similar kind is found in the disease called "pachymeningitis cervicalis," where the contraction varies according to the part of the cervical region which is affected. If that part from which the median and ulnar nerves emanate be diseased, the muscles supplied by the musculo-spinal nerve remaining intact produce the form of distortion in which the wrist is extended; while, if the upper half of the cervical region be the seat of the disease, the muscles innervated by the median and ulnar nerves produce quite a different form of distortion, in which the wrist is flexed.

Great interest has been taken of late in the effects of alcohol upon peripheral nerves, and some of our own countrymen have played a prominent part in the investigation

FIG. 42.



"Main en griffe" in a case of progressive muscular atrophy.

of them—Wilks, Buzzard, Dreschfeld, Hadden, and others. There is very little doubt that a multiple peripheral neuritis results from the circulation of this poison, and produces such symptoms as neuralgic pains, anæsthesia, paræsthesia, various degrees of paralysis and atrophy, mainly occurring in the extensor muscles, ataxia, abolition of tendon reflexes, vaso-motor disorders, and occasionally rigidity. Although our knowledge of this subject is not very advanced, it is probable that this rigidity is of the kind we are now considering—namely, rigidity of the more healthy muscles, which overpower their diseased opponents; and the latter being usually the extensors of the legs, rigid flexion results. Similarly, in cases of disease of the peripheral nerves and muscles on the extensor surface of the forearms produced by lead, rigidity of the opposing flexors is sometimes observed. As I have had an opportunity of making a post-mortem examination in a case of atrophy of the nerves and muscles of the forearm from lead-poisoning, I have brought drawings which illustrate peripheral neuro-muscular disease due to this cause. The drawings were made from microscopic preparations of the muscles of a patient aged forty-eight, a plumber, who was admitted into St. Thomas's Hospital, under the care of Dr. Bristowe, on March 18th, 1882, and died three days after admission from coma following an epileptiform convulsion. The patient had had several attacks of intestinal colic and of gout, and had also had "dropped hands" five or six years previously, from which he said he made a complete recovery. For the two months preceding his admission he had been labouring under general dropsy, and wrist-drop. His arteries were found to be rigid, his heart hypertrophied, and his urine albuminous, with specific gravity 1011. He had paralysis, with marked wasting of the muscles of the forearm, mainly the extensors, and also of the thenar and hypothenar muscles, and of the interossei.

Digitized by Google

At the post-mortem examination, the heart was found to weigh 22 oz., the valves being competent. The kidneys were contracted, hard, and granular on the surface, and weighed 8 oz. The common extensors of both forearms were pale and atrophied, and quite unlike the healthy muscles, the supinator longus being among the latter. The posterior interosseous nerve was soft and greyish, while the median and others were firm and white. The microscopic sections of the extensor muscles from which the drawings were made showed the following peculiarities (Figs. 37, 38, 39, 40, 41):—Longitudinal section: (1) Here and there were seen well-formed, large, striated muscular fibres; (2) atrophied, but striated

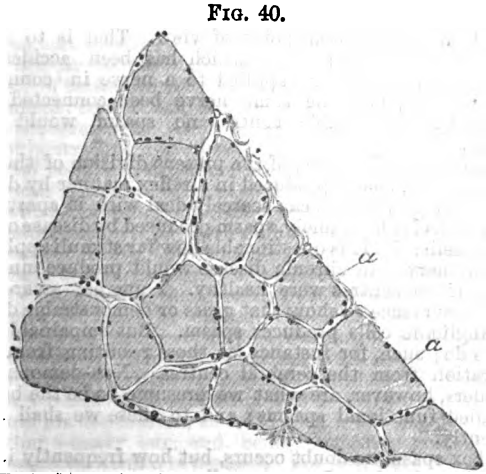


FIG. 38.

fibres, many extremely thin; (3) waxy-looking, non-striated fibres, some of fair size, some very small; (4) strands of wavy tissue, where no muscular fibres could be distinguished, but where long rows of nuclei were seen, like necklaces, often running parallel to each other, and quite close together; (5) very thick-walled vessels. Transverse section showed the muscular bundles very small, each one having a homogeneous appearance, and presenting nuclei irregularly distributed upon it. The nerves were so altered as to be incapable of recognition. The sections of the spinal cord in the cervical region showed no evidences of disease. The

FIG. 40.

supinator longus, as is well seen in the drawings, was practically healthy.

In all these and similar cases, the diagnosis depends upon the electrical reactions of the nerves and muscles in the affected part. For where the rigidity is directly produced by contraction of the affected muscles, the electrical conditions in them closely resemble those of health. Whereas, when the distortion is due to atrophy of one set of muscles, owing to disease of the peripheral nerves supplying them, what is called the "reaction of degeneration" is found in them. Setting aside such cases as these, in which the distortion is produced by rigidity, not of the diseased muscles, but of their healthy opponents, there exists still another class, in which contracture results from the shortening of diseased muscles, it is true, but nevertheless does not depend upon true spasm. We may take as an example the following case.

Case of Distortion of Arm due to Shortening of Degenerated Muscles.—On August 11th, 1885, I saw, with Mr. Clutton, a boy aged five, who had fallen down in April and fractured the lower end of the right humerus. He was treated with anterior and lateral rectangular splints for one month, and was then found to have loss of sensation and of voluntary power in the hand and forearm. The friends took him to Mr. Golding-Bird, who applied electricity daily for one month, without producing any improvement. When I saw the boy, his right forearm was rigidly pronated and the wrist partially flexed. The fingers were flexed at the peripheral joints, and slightly over-extended at the metacarpo-phalangeal joints. On attempting to overcome this condition and extend the wrist, the deep structures along the flexor surface of the ulna got tense and hard, and on bending up the elbow-joint they were again relaxed. The tips of the fingers were anæsthetic as far as the proximal phalangeal joints. The thumb had not lost sensation. The question which presented itself to us was, whether this rigidity was due to muscular spasm, or to shortening of muscles, &c., from disease. Dr. Kilner tested the muscles electrically with me, and found that, while all the extensor muscles of the forearm reacted normally, the flexors could not be brought into action even by the strongest currents. The muscles were therefore clearly in an advanced condition of degeneration. To confirm this conclusion, the child was put well under chloroform, but no change whatever occurred in the limb; all was as rigid as before. Here, no doubt, we had to do with inflammation and subsequent degeneration of nerve and muscle, and the cicatricial contraction which accompanies it. Electricity and chloroform are our principal aids in the diagnosis of such cases.

Dr. Alliott, of Sevenoaks, kindly sent me a man, aged sixty-five, who had dislocated his left shoulder-joint five months previously. On examination of the arm, almost complete paralysis of all the muscles was found with but little alteration of sensation. The elbow, wrist, and fingers were all somewhat flexed, and incapable of extension; but still there was no active contraction of muscles, for even the strongest faradaic current produced no effect in them.

In certain cases of long-standing facial paralysis, the muscles on the affected side are evidently shortened, for the angle of the mouth is drawn to that side, and the orbicularis orbis partially closes the corresponding eye. And yet the effect produced by speaking or by laughing is most curious, the affected side remaining motionless. In these cases, the electrical reactions of the muscles supplied by the diseased facial nerve show almost complete degeneration, which has been accompanied with permanent shortening.

If so many cases of distortion are due to other causes than active contraction of the muscles supplied by the affected nerves, the question suggests itself, Does chronic muscular spasm occur at all from direct irritation of motor nerves? Let us take some of the most frequent and familiar examples of peripheral nerve-disease. Musculo-spiral paralysis is often seen in quite the early stages; but we do not see, nor do we hear the patient describe, muscular spasm as one of its symptoms. The same may be said of most cases of facial paralysis due to peripheral causes. In chronic poisoning by lead and alcohol, various nerve symptoms are met with, including paralysis, and even muscular rigidity occasionally; but, as has already been pointed out, this is due to the contraction of antagonists, and not of the diseased muscles themselves. In sciatica, from various causes, we meet with twitchings and sudden muscular contractions; but they are very transitory. Again, if we look at those cases where motor or mixed nerves are pressed upon and irritated by new growths, pain is a very prominent symptom, and spasm seems scarcely to occur, though twitchings and transitory contractions are observed. A case which I have already related affords a good example of a tumour pressing upon a purely motor root. The new growth was a myxoma, which grew in connexion with one of the left anterior spinal roots, and gave rise to symptoms in the left arm. These were weakness and attacks from time to time of pain and cramp, but no prolonged spasm was ever produced.

Dr. Bristowe has written a paper on "Painful Paraplegia" in St. Thomas's Hospital Reports, vol. xii., in which h

Digitized by Google

relates several cases of paralysis accompanied by pain, which owed their origin to malignant tumours involving peripheral nerve-roots. Some of these cases I saw myself, and also examined post mortem. Evidence of spasm occurs in only one case, where the limbs are said to have become stiff occasionally.

Clonic spasm is not unfrequently seen in late stages of facial paralysis, when there is shortening of the muscle from atrophy. Electrical examination shows that the latter condition is present, and also that a certain amount of muscular tissue, capable of active contraction, remains. The clonic spasms result from irritation of the nerve and muscle which has survived the process of destruction. In cases of meningitis at the base of the brain, spasm of the muscles supplied by the motor nerves involved is not observed. In spinal meningitis, on the contrary, it is a very marked symptom. Here, however, it is not improbably of a reflex origin, and not due to direct irritation of motor nerves.

Tetany (Fig. 43) is a disease in which the presence of some, although generally trivial, alteration of sensation, increased electric irritability of nerve and muscle, and prolonged muscular spasm suggest a peripheral cause. The pathology of this affection cannot be said to be known, and opportunities of examining cases post mortem rarely fall to the lot of pathologists. Dr. Hadden kindly gave me the opportunity of examining microscopic sections of the nerves and muscles of the affected parts, which were taken from a child who died from diarrhœa while suffering from tetany. At first I thought there were changes to be made out, but

FIG. 43.

The hand in a case of tetany.

on procuring sections from the same parts in a healthy child of the same age (sixteen months), who had died of an acute disease, and comparing them with those from the subject of tetany, I came to the conclusion that there was very little difference between them. Looking at my own experience, I should say that while occasional spasm occurs not unusually in peripheral nerve disease, from direct irritation of the motor filaments, and may even be permanent in disease of the facial nerve, it is quite the exception to find muscular contractions among the marked phenomena of such cases.

Weir Mitchell, who has had a very large experience of injuries and diseases of peripheral nerves, writes thus on the subject:[1] "Increase of bulk, proliferation of connective tissue, and wasting of nerve tubes are consequences of chronic neuritis..... The nerve tubes in large part perish or waste, and the symptoms affect at first rather the sensory sphere than that of motility. We have pain and anæsthesia, or hyperæsthesia, but not, as a rule, local convulsions..... In certain cases the nerve-wound, in place of causing primary loss of motility, occasions either sudden muscular contraction, followed by instant loss of power, or, in very rare instances, long-continued spasm..... Tonic contractions of muscles are occasionally met with at a later stage of these injuries, but are, perhaps, among the rarest of the secondary symptoms." Looking, then, at the experience of Weir Mitchell and others, we may safely conclude that muscular spasm is rarely caused directly by chronic disease of peripheral motor nerves.

[1] Injuries of Nerves and their Consequences, 1872.

2. *Spasm produced in a Reflex Manner by Disease of Afferent Nerves.*—There is scarcely a more difficult subject in the whole range of nerve pathology than that of reflex spasm. Cases of general convulsions, as well as of local spasm, are so frequently explained in this way, and are in so many instances quite insufficiently supported by scientific evidence, that one cannot help coming to the conclusion that many cases are accepted as of reflex origin which, at any rate, carry very little conviction with them. Some reasons can be adduced for the difficulties which beset the diagnosis. Many of these cases occur where some sensory nerve is the seat of severe pain, or where a part is diseased which is painful to move. A good example of the former class are spasms of the muscles of the face, accompanying facial neuralgia; and of the latter, rigidity in joint disease. But the most ordinary method of expressing pain is by some over-action of the facial muscles; while the ordinary way of preventing pain in joint disease is by keeping the joint still, and opposing attempts at movement, by contraction of muscles which produce an opposite effect. This is so natural a contrivance, not only in man, but in the lower animals, that it must be looked upon as almost an involuntary act. Reflex muscular acts are in very different degrees capable of being controlled or modified by the will, and even if it be allowed that the latter plays a part in the limitation of the movements of a diseased joint, this does not prove that the act is not partly involuntary and reflex. In many cases it is very difficult to form a definite conclusion with regard to this question.

No one who observes the great variety in the degree of reflex muscular contraction produced by similar stimuli applied to different individuals can be surprised at finding evidence that persistent spasm occasionally occurs as the product of a reflex act, or that a stimulus which produces no motor result in one person gives rise to definite muscular contractions in another not equally healthy. Thus in hemiplegia accompanied by descending sclerosis in the lateral columns deep reflexes are much more brisk than they were before the hemiplegia occurred; and contractures, Brissaud says, may be suddenly increased by comparatively slight injuries. If this increased reflex excitability be due to the hyperphysiological activity of the spinal centres, which have been loosed from cerebral control, similar disorders of nerve centres rather than of nerve fibres are probably the most fertile causes of reflex spasm. So that it is scarcely too much to say that the injury or disease which supplies the stimulus to the sensory nerve in such cases, though apparently the principal agent, is really so in many instances only from a particular point of view. That is to say, a mine exists in the patient which has been accidentally exploded by a stimulus applied to a nerve in connexion with it; but, had the same nerve been connected with a healthy and stable centre, no spasm would have ensued.

In speaking, therefore, of the present division of the subject—namely, spasm produced in a reflex manner by disease of afferent nerves—we can scarcely deal with it apart from the next division—namely, spasm produced by disease of ganglionic cells; for it is questionable how far stimuli applied to afferent nerves in chronic disease would produce muscular spasm if the centres were healthy. I am not aware that there is evidence to show that gross or demonstrable disease of ganglionic cells produces spasm. But impalpable disorders do; such, for instance, as those resulting from their separation from the cerebral centres. Non-demonstrable disorders, however, are what we presume to be the basis of so-called functional spasms; and to these we shall revert presently.

Reflex spasm no doubt occurs, but how frequently it does so, or how far the afferent or efferent nerves or the nerve centres take the leading part in its production, are points which can scarcely be estimated. As good an instance as I know of reflex spasm is recorded by Mr. Clutton in the St. Thomas's Hospital Reports (vol. x., p. 64). A boy, aged fourteen, had been bitten in the face by a dog eighteen months previously. The spot had been painless until a month before his appearance at the hospital, but since that time he had suffered from constant shooting pains in the neck, which always started from the scar. At the same time that the pain was felt, the angle of the mouth was drawn outwards, and the skin of the neck was wrinkled by the action of the platysma; the whole side of the face and neck blushed, and then became bathed in perspiration. This succession of symptoms recurred every time the boy

Digitized by Google

pinched. Croton chloral hydrate in five-grain doses twice a day soon cured the affection.

Weir Mitchell, in his work on Injuries to Nerves, gives instances of reflex muscular spasm; and this condition is often referred to intestinal, uterine, or other irritation, but often without sufficient reason. Charcot has written a good deal in support of the view that various affections of joints may give rise to rigidity of muscles in a reflex way; and it certainly is very difficult to explain them otherwise. The following case appears to me to be one of this kind.

Case of Persistent Muscular Spasm due to Joint Disease.—F. W——, aged sixteen, was an out-patient at St. Thomas's Hospital, under the care of Mr. Clutton, in February, 1884. I saw the case with him, and the following is the clinical record which he took while the patient was under his treatment, and which he has kindly put at my disposal. She was sent to him by Mr. Mercer, of the Bath Mineral Water Hospital, with the following history. During May, 1883, she had had rheumatic fever, and the joints chiefly affected were the wrists and ankles. For three months the wrists were placed in splints, and in the autumn of the same year she was sent to Bath with perfectly stiff fingers and wrists. Passive movement was employed, which made the fingers pliable, but which left the wrists as stiff as ever. The accompanying illustrations (Figs. 44 and 45) show the condition which existed when the case came under Mr. Clutton's notice. The photograph was taken by Mr. Charles West. Both hands were in the same condition. On attempting to move the wrist-joint, the flexors and extensors alike resisted, and could not be overcome. Taking them by surprise produced no better results. When the patient was placed under ether, the muscles yielded to attempts at flexion and extension, but the rigidity did not entirely disappear. There were but few adhesions in the joint, and these readily gave way under the anæsthetic, but left the state of affairs practically the same as before—that is to say, the wrist could be flexed or extended, but on removing the force the hand again assumed the position shown in the illustration. When the wrist was extended the fingers always became flexed, and when it was flexed they became extended. The patient could voluntarily extend or flex the phalanges, and could separate the fingers. The thenar muscles also acted normally. The wrist was rigid, and could not be moved in either direction, and there was slight hyper-extension at the metacarpo-phalangeal joints, which was easily overcome voluntarily when the patient flexed the fingers. Dr. Kilner tested the electrical condition of the nerves and muscles, and found it normal.

Let me here briefly refer to a class of spasmodic affections which appear to have the same explanation as tendon reflexes. Whether explicable as a reflex or purely local phenomenon, contraction of muscles occurs when they are put on the stretch by their antagonists; and this has the effect of controlling and steadying movements which might otherwise be jerky and uncertain. When the influence of the lateral columns of the cord is removed, the spinal centres in which reflex acts are produced in relation with parts below the level of the lesion are brought into a state of excessive activity, and stretching of a tendon produces an abnormally sudden and extensive contraction. This is very probably the cause of the tremors in the direction of movement seen in cases of disseminated sclerosis. But it is probable that some cases may have a peripheral origin. A medical friend of mine informed me that he once took a vehicle in order to drive to a house where he was going to stay for a while. The driver put him down two miles and a half from his destination, and drove off. The medical man had rather a heavy bag, and, being unable to get another conveyance, he carried it himself. For four days after this walk he suffered from pretty constant contractions of the triceps muscle of his right arm, whenever he flexed the latter. In this instance the muscle had been what we call strained, the tendon had been unduly pulled upon, and when the arm was flexed the slight increase of tension made the triceps contract. Such a case represents a very small departure from the normal, but suggests an explanation of more troublesome affections—such a one, for instance, as the following.

Case of Persistent Rhythmical Contraction of the Palmaris Longus, due to Injury.—On July 7th, 1878, I saw a girl, aged nineteen, who had had her wrist bent backwards and sprained five years previously. The parts injured had swelled, and she had been obliged to carry her arm in a sling for some weeks. Ever since that time she had suffered without intermission from twitchings of the arm and palm of the hand. On examination, I found that the general power of the arm was unimpaired, but that there were spasmodic contractions of the palmaris longus muscle, occurring with perfect regularity ninety times in the minute. The contractions were energetic, and showed the muscle and its attachments very beautifully. In this case, probably the palmaris longus had been stretched, and the peripheral nerves ending in it had been rendered more irritable, the result being that the slight tension of it, which occurs ordinarily in the act of extending the wrist, caused the muscle to contract. This, occurring frequently, gave rise to a neuro-muscular habit.

The following is a somewhat similar instance. Mr. Clutton once showed me a girl, aged ten, who had fallen down a week previously and slightly sprained her right wrist, but had done herself no other damage. I found her suffering from an affection which had come on immediately after the fall. Her right arm was in a position midway between pronation and supination, and was the seat of perfectly regular tremors of very small excursion, such as one sees in paralysis agitans, occurring in a direction transverse to the longitudinal axis of the limb.

Other pathological conditions, as well as injuries, may produce these rhythmical spasms. In January, 1886, a girl, aged fourteen, was in St. Thomas's Hospital, under the care of Dr. Bristowe, for rhythmical contraction of the occipito-frontalis muscle on both sides, which occurred from fifty to sixty times in the minute, and had been going on for some months. The history she gave was that she had had a very bad attack of "erysipelas of the face," commencing on the forehead and spreading downwards. The onset was sudden, and the description she gave of the affection corresponded with that of erysipelas. Roughness and pigmentation of the skin of the forehead could still be seen. As the disease got well, the contraction of the occipito-frontalis muscle supervened, and continued for months without intermission, except during sleep. The original cause of this condition was probably an irritable state of the muscle and tendon owing to inflammation, and an involuntary neuro-muscular habit was soon developed. Although the girl showed no evident hysterical peculiarities, I found that she had marked localised tenderness over those regions which Charcot has found to be unduly sensitive in hysterical subjects. Moreover, information which I subsequently obtained proved that at least one other member of her family was hysterical, for, while the patient was still in the hospital, her sister, aged eleven, was admitted under Dr. Bristowe's care, suffering from a similar affection. The latter had been under me as an out-patient for fits, which were evidently hysterical; and at the early age of eight years she had had an attack of rhythmical spasm of the occipito-frontalis muscle, which lasted three months and then got well. When I saw her in the hospital during the second attack, I found that the muscle was contracting pretty regularly 120 per minute, and this condition was accompanied with sighing, yawning, slight movements of the tongue, partial loss of sensation on the left side, pain in the left hip and knee, and drawing up of the left leg so as to produce distinct shortening.

Other cases of spasm from peripheral injury are more complicated, but appear to be reflex in their origin, whether the pathological stimulus acts upon the nerves which exist in muscles and tendons or upon other afferent paths. The following is an example.

Case of Spasmodic Movements of the Jaw, the Floor of the Mouth, &c., due to Injury.—On Nov. 20th, 1877, a boy, aged ten, came to St. Thomas's Hospital on account of a peculiar affection which he had had for five days. There was nothing noteworthy in his family or personal history, except that he had suffered from incontinence of urine. Five days before coming to St. Thomas's he had been in a playground where his schoolfellows were having a game of football. He happened to be in their way, and one of them took him by the back of the neck and threw him to one side. His neck pained him at the time, but by the following day the pain was gone. In its place, however, was a peculiar affection, consisting of constant movements of the lower jaw and of the floor of the mouth, and they had increased since then. As he stood in front of me, I saw the lower jaw and the floor of the mouth descend in regular and frequently recurring jerks, and when the boy's mouth was open it was seen that the tongue was likewise jerked spasmodically downwards and backwards. In addition to this, the larynx

Digitized by Google

descended slightly, and the depressor muscles in the neck could be seen contracting. Each downward movement was accompanied by a sound like the croaking of a frog. Neither the faradaic nor the galvanic current applied from the nape of the neck to the parts below the jaw had the slightest effect on this curious condition. I gave the child some bromide of potassium, and sent him away. Nine months after that I saw him, and he was nearly but not quite well.

As I have already said, it is a matter for speculation how far such causes would give rise to spasm, if the nerve-centres were in a normal condition. What is really developed in these cases is an involuntary neuro-muscular habit. We are all familiar with the ankle-clonus which is set up sometimes in healthy people when sitting with the toes on the ground and the heels a little raised. If we start the clonus voluntarily, or if it has occurred several times in succession involuntarily, it may be difficult to stop it by an effort of the will, unless the position of the legs be altered. This is probably a physiological representative of certain cases of muscular spasm which assume pathological dimensions.

I have now come to the end of the remarks I have to make upon the first two divisions of spasmodic affections in connexion with chronic nerve disease—those, namely, which result from pathological changes in the cerebral motor mechanisms on the one hand, and the spinal motor mechanisms on the other. The third division, and that the most difficult of all, remains still to be dealt with, and is coextensive with what are called functional spasms. As I have already pointed out, the first two divisions should, and we may hope some day will, cover the whole field of spasmodic affections; and by placing functional diseases under a separate heading we publicly confess our ignorance, and proclaim that there is a very long list of spasmodic affections which have been carefully observed without success, so far as their pathology is concerned. In lectures professing to deal, however perfunctorily, with spasm, it would be impossible to pass by in silence the class referred to. It remains, therefore, for me to consider how far these functional diseases are capable of explanation or reasonable classification.

(To be concluded.)

ABSTRACTS OF THE

Lumleian Lectures

ON THE

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

BY WILLIAM H. STONE, M.A., F.R.C.P.

LECTURE I.

AT the outset Dr. Stone asserted that he was not going to treat of so-called medical electricity. Electricity had not risen to expectation as a means of treatment of disease. To say that electricity is life is untrue. He proposed to treat of certain physical conditions of the human body in its relation to electrical currents, and to concern himself more with the inorganic and physical than with the physiological side of the problem. The importance of placing the physiological and medical application of electricity on a physical basis of absolute measurement was obvious. The earlier methods of detecting and estimating the existence of electrical currents were too indefinite and unmeasured to be of any scientific value. The galvanoscopic frog was a delicate but uncertain method of estimation—entirely empirical and unmeasurable. Professor Hughes had shown that the telephone can be used in the place of a galvanometer; this was demonstrated to the audience by telephones placed at intervals round the room, and the intensity of the sound in the instrument was made to vary by increasing and diminishing the distance between the primary and secondary coils.

Dr. Stone next proceeded to the main subject of his first lecture, which was to determine the resistance of the human body to the passage of electricity. Previous workers on the electrical conditions of the human body had been unable to estimate its resistance, or had made very erroneous statements from a variety of causes. Dubois-Reymond, Count du Moncel, and others had worked at the subject of animal electricity, but with scanty results. Volta, Humboldt, Lenz, Fechner, and Gilbert had all investigated the subject of electrical resistance of animal tissues. Dubois-Reymond practically gave up the problem of estimating the electrical resistance of the body as a whole. Serious errors were made because the occurrence of polarisation was not taken into account. The resistance, moreover, varied greatly, as Dr. Stone was the earliest to show, according as a low tension be employed or one of high tension, as from the induction coil; the resistance, indeed, was totally and entirely different in the two cases. The Count du Moncel experimented on his wife, and at least succeeded in demonstrating the electrolysing capacity of animal tissues, as permanent scars left by tremendous ulcers testify in the person of the lady to this very day, though the Count has long since gone to his last rest. He estimated the resistance of the body to electricity in terms of the Swiss and French unit, this being taken as one kilometre of telegraph line. Actually his numbers were 350 to 220 kilometres of telegraph line as the approximate resistance, but he employed very small electrodes, and this vitiated the result, as Dr. Stone afterwards showed. Still it was astonishing, considering the imperfect methods used, that so near an approach was made in ascertaining the real resistance of the body. The Swiss unit of one kilometre of iron wire is equal to about 10 ohms. The Count's lowest estimate of 2200 ohms (220 kilom.) was not grossly inaccurate.

The two chief difficulties that exist in the estimation of the resistance next occupied attention. One was the difficulty of making good contact. The older workers never made good contact. Electrodes 4½ cm. by 3½ cm. were employed; these being not nearly large enough. The body might be regarded as a cable, consisting of a mass of conducting material contained in a good insulator. In dry atmospheres human skin rubbed against woollen tissue developed electricity with facility, and this was the explanation of the electrical boy, who by friction on the carpet developed electricity. Again, the human body rapidly electrolyses; it might be regarded as a secondary battery of no inconsiderable power. It also had what Dr. Stone formerly spoke of as electro-chemical capacity, the body being regarded as a condenser. But in order to be in harmony with the recent results of Professor Hughes this capacity would better be named self-induction. It was most important to determine the resistance of the tissues which were insulated by the skin. In order to arrive at it we should make the contact, mathematically speaking, infinitely large. The resistance due to the skin Dr. Stone showed by using salt-and-water, and very large leaden poles could be brought down to zero. He obtained, in fact, the best contact by using a broad ribbon of lead wound round the skin, which gave very perfect contact over a sufficiently large area. The variability of result as to resistance owing to the high insulating power of the skin could be done away with by obtaining perfect contact. Estimations were made from definite anatomical points; the styloid process of the ulna and the external malleolus of the fibula were very useful for the purpose. Instead of the deflecting galvanometer he used Wheatstone's bridge, or a modification of it. Small bichromate batteries were good, but pure chromic acid ones even better. Each of these elements gave an electro-motive force of two volts. As electrodes he had tried powdered wet carbon, spongiopiline, and surgical serrefines inserted through the skin. The last was exceedingly painful, and the others not so good as leaden appliances. By allowing the current to pass from foot to foot the largest quantity of tissue could be operated upon; from hand to hand was also useful, but those estimates taken from hand to foot were of great value. The distance from one hand to the other corresponded fairly to a man's height. The following table shows some results from the living human conductor:—

	Height.	Measurement from hand to foot.	Resistance. Foot to foot.	Foot to hand.
	ft. in.	ft. in.		
Mr. T——	5 6	5 9½	945 ω	1320 ω
Mr. S——	6 3	7 0	930 ω	1027 ω
Hungarian giant ...	7 6	8 7	930 ω	1032 ω

The resistance might be measured by using momentary contacts; the results were, however, vitiated by electrolytic action that was set up by the electrical current acting on the tissues, a counter electro-motive force being set up. By

Digitized by Google

employing alternating currents errors also crept in, owing to the electro-chemical or voltametric capacity of the human conductor. The resistance of a St. Thomas's Hospital porter's tissues by using the alternating currents was determined with the aid of a galvanometer and found to be 1160. But polarisation setting in causes usually a steady rise in the resistance; chemical decomposition taking place inside the body develops an opposing electro-motive force. Dubois-Reymond asserted that he had not taken the trouble to ascertain the human resistance, but Dr. Stone believes that he really gave it up in despair owing to his obtaining such variable results. The lecturer said that at the suggestion of Dr. O. Lodge he had adopted Kohlrausch's principle, the apparatus consisting of an induction coil and telephone. This will be explained in another lecture.

Reference was next made to Sir Henry Mance's method of measuring resistance; this eliminated the errors due to polarisation and electrolysis. The body might be regarded electrically as a faulty submarine cable; it was for this that Mance employed his method, but Dr. Stone now used it for investigations on the human body. It appeared that Mance had already made a few observations, and actually determined the resistance of the human living conductor at 900 to 1100 ohms. Rosenthal's estimate of 8 to 20,000 ohms was much beside the mark. In Mance's method a modified Wheatstone bridge was used; it allowed polarisation to do its worst. The following simple formula showed the method of estimation of resistance:—

Let P_1 = R. of coil A and P_2 = R. of coil B
R_1 = R with coil P_1 and R_2 = R with coil P_2

Then $$X = \frac{(R_1 - P_2)(R_2 - P_1)}{(P_2 + R_2) - (P_1 - R_1)}$$

Or $$X = \frac{A - B}{C}$$

It was ascertained by experiment on the porter that the resistance rose 7 ohms from polarisation, and Dr. Stone stated that, as a rule, the resistance increased whilst the current was passing through the body. Some observations had been made by other investigators and at different times than those of his own—especially Mr. Lant Carpenter; and it was interesting to note that the results were practically the same, though different kinds of apparatus had been used. Thus with an electro-motive force of 2 volts the resistance for the first minute was found to be 1194 ω, but at the fourth minute 1230 ω; with 4 volts at the fourth minute, 1155 ω; with 8 volts (Dr. Stone) the first minute gave 1130 ω, the fourth minute 1160 ω. It seemed clear, then, that the human resistance was much less than had hitherto been supposed. Further, Dr. Stone found that if the patient had been in sound health the size of the individual made no difference, as the table already given shows, where, if anything, the smallest man gave the highest resistance. As is the length of the levers of the body so is the sectional area of the muscles that move them. He would not assert, however, that the law was universal. In disease considerable differences obtained. Mr. Cunynghame had taken the resistance of the human body as 2000 ohms, with a view to determine the real limits of safety for electric lighting, and this was a difficult matter. Accidents happened with powerful dynamos, but it was almost impossible to ascertain their frequency or anything about them; they were seldom made public, and generally hushed up, probably because it was thought by the promoters of electricity for useful purposes that publicity of the facts relating to accidents might interfere with the future success of the industry.

Dr. Stone next considered a few of the alterations in resistance that occurred in certain diseases. The point was not yet settled whether the human body acts as a solid or as a fluid conductor; the behaviour of fluids and solids to heat showed that there was a considerable difference in their molecular structure. In his opinion the tissues did not act as fluid conductors. It was ascertained that dropsy enormously reduces the resistance. It sank to one-half in one case which Dr. Stone had the opportunity of investigating before and after the appearance of dropsy; this did not seem as if muscle acted as a fluid conductor. In fact, muscle was more resistant in good condition than when replaced by connective tissue. The lecturer had investigated six cases of very old hemiplegia; the difference of resistances respectively between the sound and diseased side were 420, 350, 360, 120, 550, and 730 — results so different from the normal 1000 that he considered them as not to be explained by mere accident. Certain cases of impregnation of the body by metallic impurities were also ascertained to alter considerably the resistance to the passage of electricity Thus in a case of mercurial intoxication there was a considerable increase in the conductivity of the tissues, which was not so marked in lead-poisoning. In a case of impregnation by copper, where the right hand was most affected, it was found that this hand gave less resistance—was, in fact, a better conductor than the left. The urine in this case was decomposed by electrolysis and 3 milligrammes of metallic copper obtained. As to the influence of pyrexia, Dr. Stone quoted some results, which have already been published in *Nature*, in a case of ulcerative endocarditis; the general result, which requires confirmation by further observations, was to the effect that the resistance in fever is greatly decreased.

THROMBOSIS OF THE CORONARY ARTERY DURING ETHER ANÆSTHESIA.

SUDDEN DEATH AFTER THREE WEEKS.

BY WALTER MOXON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

MR. PETER GOWLLAND had operated for some anal trouble upon a gentleman who was staying at an hotel in Finsbury. The wound had healed; it had been only a small incision, not confining the patient to bed. At the time of the operation ether was administered, and it was noticed that a great deal of ether was required to produce full anæsthesia, but beyond this no signs of any unusual occurrence were observed. Three weeks after the operation the patient was found dead on his bed. The body was naked, already cold, and in full rigor mortis; it was twisted as in suffering, the face turned to the pillow. A light was burning in the room, the time being near midsummer. From all the circumstances it was evident that the deceased had been seized with sudden illness, and had died as he was undressing for bed. A brother who had been a good deal with him in the last few months said that there had been no complaint made by him. A servant at the hotel had seen Mr. Gowlland's patient go upstairs to his bedroom about 11 P.M. on the night of his death, and had noticed the alacrity with which he ran up the stairs; she remarked that he appeared to be an active, vigorous sort of person, in good spirits.

On inspection, seventeen hours after death, the body was well nourished and younger looking than the stated age. There were no signs of decomposition. The examination discovered nothing whatever of a morbid nature except in the vascular system. The state of the heart at once drew attention. Its left side, especially the ventricle, was much distended with liquid blood, the right cavities being distinctly less loaded than usual. The substance of the heart was very soft and flabby, although rigor mortis was strong in the trunk and limbs. The endocardium and endarterium were stained red, showing that the red blood-corpuscles had partially disintegrated since death. The relatively empty state of the right heart, taken with the distended condition of the left, proves that the cause of death had not been any kind of obstruction to respiration, but was due to failure of the left ventricle after the left auricle had acted. Death was due to syncope in cardiac diastole. On proceeding to examine the heart more narrowly, the course of the coronary vessels could be traced with the finger, these arteries feeling like threads of stone in the rather considerable amount of fat which followed the lines of the inter-ventricular grooves. The inside of the aorta was found, on the other hand, to be in a good state of preservation for the age of the individual. There were but a few patches of quite superficial degeneration, and these did not implicate the mouths of the coronary arteries, which were of normal size, readily admitting an ordinary probe. But on opening up the left coronary artery with a fine pair of scissors, its walls crackled and broke, with a fractured stony edge, and this went on as the course of the vessel was followed until reaching about two-fifths of the way down towards the apex of the heart. At this point the channel of the vessel proved to be partially obstructed.

Digitized by Google

It was the point of origin of a rather large branch, which went towards the left ventricle, and this branch was filled with a thrombus, which projected into the channel of the parent vessel, so as to almost close it. It should be noticed that the blood everywhere else was quite liquid. There was no clot in the aorta nor in the coronary artery, except the little clot in this branch of the vessel, and this clot was of pale colour and firm consistence, and adhered to the vessel's wall; but the end of it, which projected into the main coronary artery, was dark in colour and of recent date.

In the interpretation of these facts the first question is whether the clot was embolic, or whether it arose in the place where it was found. I think there can be no doubt of the autochthonous origin of the clot, seeing that no source of embolism was discoverable, and that the clot was in a particularly narrowed, tortuous, and stony part of the vessel, conditions favouring the coagulation of the blood there. Further, it should be noticed that the thrombus occupied the part of the coronary system of vessels which is most prone to disease. Now it is beyond measure improbable that a solitary embolus would find its way to this special point, whilst this is the very point where a thrombus would take its rise. The locality is thus a practically decisive reason for believing that the coagulation occurred in the affected branch of the coronary vessel, and as negative ground for the same conclusion no source of embolus could be found; the valves and the lungs were quite healthy. The age of the thrombus would correspond to about three weeks, so far as my experience enabled me to judge; and this was the period that had elapsed since the anæsthesia by ether had been undergone. It is therefore obvious that the clot formed about and probably at the time of the ether administration, three weeks before death. This being admitted, it will be seen that the heart showed itself able to maintain the circulation in a manner very satisfactory whilst it lasted; so that its possessor was noticed to be robust, cheerful, and active at a time when a clot of more than two weeks' date had closed a very considerable branch of the arterial supply of the left ventricle. The state of the muscle of this part of the ventricle was carefully examined, and I was not able to see any marked difference between the muscle fibre of the part whose artery was obstructed and the rest of the fibre of the ventricle. There were here and there a few fibrils with traces of granular change, and there was some brown pigment about the nuclei of some of the fibrils. The formation of the thrombus was probably by extension from a small beginning, or more degeneration must have occurred in the muscle. It must be concluded that anastomotic twigs carried on sufficient circulation till shortly before death.

The effect of experimental occlusion of a large branch of coronary artery upon the heart of a mammal has been stated by several observers.[1] The facts observed have varied somewhat with the kind of animal experimented on. The heart of a dog thus treated was found to continue its action for a short time quite efficiently, so that the arterial pressure was fully sustained until the rhythm of the contractions was suddenly lost and the heart stopped at once, the last beats of the auricles distending the ventricles, whilst these became utterly insensitive to any kind of stimulation, and death took place with the heart in diastole. But in order to make such an experiment the heart has of course to be exposed and maltreated; and under these circumstances it is apt, independently of interference with the coronary arteries, to go wrong in the manner described. Cohnheim's account of the behaviour of the heart corresponds with what is known as "delirium cordis." My friend and colleague, Dr. Wooldridge, who speaks on this matter with the authority of large experience, writes to me as follows:—"I have often seen a gradual failure of the heart from long maltreating. I have never seen it stop suddenly, except as the result of the development of delirium of the heart, so that the fibres or groups of fibres in the ventricle work away at a great rate in their own time, but not in harmony with one another, so that a very wriggling condition is set up. Meantime the auricles go on beating and the ventricles become very distended. Delirium of the heart may arise from faradaic excitation of the heart (localised faradisation), and also by mechanical injury, sticking in needles, &c. I have also seen it arise from strong constant current, and it arises with peculiar readiness in dogs poisoned by chloral. I have seen it occur *spontaneously* in an exposed heart."

[1] Von Bezold: Med. Centralb., 1867. Samuelsohn: Zeitschr. f. Klin. Med. Cohnheim: Allg. Pathol.; i., 34.

The suddenness of death and the great distension of the left ventricle in the present case correspond exactly with the description of Cohnheim and others of the mode of death witnessed in experimental closure of a large branch of the coronary artery; and a large branch of the coronary artery was, in fact, closed in the case narrated. The experiments enable us to follow what took place. Death in these cases appears to be due to delirium cordis, and the facts observed in Mr. Gowlland's patient render it probable that delirium of the heart may be set up without exposure or maltreatment if a large branch of the coronary artery be stopped. The small dark recent portion of the clot which extended from the old clot of the branch into the parent vessel would serve to suddenly starve a much larger area of ventricular muscle, and so imitate exactly Cohnheim's experiment, save only that the obstruction was not complicated by operative maltreatment of the heart. I think the case must be added to the list of deaths through inhalation of ether.

SECONDARY INFLAMMATION OF THE PAROTID.

BY STEPHEN PAGET, F.R.C.S.

PAROTITIS, not due to mumps, may be due to local injury, or may occur during one of the acute fevers, usually typhus. It also occurs in pyæmia; and of this true pyæmic parotitis I have collected many cases. But the following cases make up a fourth group; a few of them, but only a few, are cases of pyæmia. In all, the primary lesion was in the abdomen or pelvis. In nearly all, the parotitis was the only secondary lesion. Most of the patients recovered; and in many cases the absence of all signs of pyæmia or septicæmia was especially noted. It is probable therefore: (1) That the parotid is related to the peritoneum; (2) that it is also related to the generative organs; (3) that an abdominal or pelvic lesion may be followed by parotitis without pyæmia; and (4) that such a parotitis, if it occurs late, in a patient not exhausted by the primary trouble, and with healthy kidneys, is usually followed by recovery. This relation of the parotid to the abdomen and pelvis was called by old writers a "sympathy." It is probably very complex; it may include the minute structure and chemical and vital changes of the parts concerned; their vascular, lymphatic, and nervous connexions; their liability to diseases; their inherited and embryonic tendencies.

But even if all the following cases were cases of pyæmia, which they are not, we should still have to ask why pyæmia starting in the genito-urinary system is more often the cause of parotitis than pyæmia starting in the limbs. This question has made me examine the relation, in pyæmia, between the site of the primary lesion and the distribution of the secondary abscesses; I hope soon to publish some statistics on this point; certainly the distribution is not a matter of chance. Thus disease seems to be able to demonstrate relations between organs which in health appear independent. My best thanks are due to those gentlemen who have kindly told me of cases.

CASE 1. *Use of the catheter; parotitis; death.*—A gentleman aged eighty, with enlarged prostate and residual urine, had used a catheter twice a day for two months; then he insisted on its being passed more frequently. A week later his bladder became irritable; then came a rigor and acute right parotitis. Death in forty-eight hours. No pus was observed in the urine.—(THE LANCET, February, 1886.)

CASE 2. *Use of the sound; parotitis; death.*—A gentleman aged eighty-five, with slightly enlarged prostate and irritable bladder, who had often used a catheter, was sounded, easily and without much pain. Next day there were violent rigors and right parotitis, which ended in suppuration. Death in fourteen days from exhaustion.—(THE LANCET, January, 1886.)

CASE 3. *Use of the catheter; parotitis; recovery.*—A gentleman aged eighty-two had used a catheter, and a false passage had been made. He then had retention; relieved with a catheter properly passed. This was followed by swelling of one parotid. It did not suppurate, and he recovered.—(MS. case.)

CASE 4. *Use of the catheter; cystitis; parotitis; death.*—A gentleman aged eighty-four, with irritable bladder and

Digitized by Google

much residual urine, began the daily use of a catheter on Sept. 8th. Two days later he was feverish, passing bloody urine. On the 27th he was thought to be dying; but on this day the right parotid became swollen, and with this his condition improved. The gland suppurated, was incised, and began to heal; but he afterwards sank steadily, and died on Oct. 14th.—(MS. case.)

CASE 5. *Cystitis; parotitis; recovery.*—A lady over seventy-five, with chronic cystitis and leakage of urine, was laid up after a fall. This made her cystitis worse, and three or four weeks after the accident she had swelling of one parotid, with dusky redness of skin over it. Slow suppuration followed, revealing a sloughing mass almost as large as a walnut; this by degrees became detached and was cast off. Two months after the accident all was healed, and she is still alive and active.—(MS. case.)

CASE 6. *Peritonitis (?) after delivery; parotitis; recovery.* A primipara, aged twenty-eight, suffered from tenderness of the abdomen on the day after delivery, and this was followed by "septicæmia." The perineum had been slightly torn. On the nineteenth day she had inflammation of the right parotid, with rapid swelling of the face and neck, "so that tracheotomy seemed inevitable." In six days the parotitis was nearly gone. A week later it returned, but only for two days. Rapid recovery.—(*Amer. Gynæc. Trans.*, iv., 125.)

CASE 7. *Induced abortion; parotitis.*—C——, aged forty-one; six children. Pregnancy at third month. Salivation great. Abortion induced for pernicious vomiting. Five days later acute left parotitis; no womb-symptoms, but slight fever and sour-smelling discharge.—(Dr. J. M. Duncan. M.S. case.)

CASE 8. *Peritonitis after delivery; parotitis; recovery.*—A young woman, with severe peritonitis after delivery, was treated with mercury internally and externally. The peritonitis improved, but mercurial stomatitis came on with right parotitis. This was resolved; then came left parotitis. Early incision, without waiting for fluctuation; gland infiltrated with pus. Rapid relief.—(*Gazette Hebdom.*, 1868.)

CASE 9. *Retarded convalescence after delivery; parotitis.*—A lady was confined of her second child on Jan. 25th. Labour natural; but uterine pains continued, giving her no rest, and her temperature kept about 101°.—27th: She has passed a large clot; the uterus is large and somewhat tender; syringed out with carbolic (1 in 40). In the evening very cold, with teeth chattering.—28th: Temperature 103°; pulse 140; tongue very dry.—29th: Better; uterus much smaller.—30th: Uterus larger again; syringed out. Much flatus in intestines. There was never at any time any offensive vaginal discharge.—31st: Much flatus; tongue as hard and dry as ever; temperature 103°.—Feb. 2nd: Urine normal; temperature 100°.—3rd: Complains of pain at right angle of jaw.—4th: Right parotid greatly enlarged; she cannot open her mouth.—5th: Much less swollen. Tongue still very dry.—7th: Swelling gone; temperature and pulse normal. There were never any offensive lochia or any signs of peritonitis. There was a drain wrong in the house, or said to be wrong, and a lady previously living there had been ill after her confinement there. (Dr. Godson. MS. case.)

CASE 10. *Pyæmia after delivery; parotitis; death.*—A primipara, aged twenty-nine; delivery with forceps; extraction difficult; ruptured perineum. On the third day peritonitis with fever and vomiting, followed by jaundice, pains in the chest, and dyspnœa, with rapid loss of strength. The uterus was kept irrigated. Shortly before death swelling of the left parotid. Death on the ninth day. Post-mortem: Laceration of vagina; endometritis; abscesses in broad ligament; diffuse suppurative peritonitis; spleen swollen; chronic interstitial nephritis; fresh adhesive pleurisy; infarcts in right lung; pulmonary œdema.—(*Amer. Jour. Obstet.*, 1884.)

CASE 11. *Delivery; puerperal mania; parotitis.*—A multipara, aged twenty-eight. March 7th: Natural labour.—19th: Left parotitis.—20th: Maniacal.—28th: Parotitis going down; temperature normal. Case still under treatment.—(Mr. Brockatt: St. Thomas's Hospital.)

CASE 12. *Pyæmia after delivery; parotitis; death.*—A multipara, aged thirty-six. Delivery by section of the child; it was an arm presentation, with firm retraction of the uterus. Temperature the same day 105°. Next day, temperature 105·5°; pulse 140. She had repeated shiverings, and continued to get weaker.—Ninth day: Moved into St. Bartholomew's. Very weak; face sallow; abdomen tender; sordes on lips.—Tenth day: Rigor; temperature 102·8°.—Twelfth day: A tender swelling in the right maxillary region; skin over it glazed. Tongue dry; no offensive discharge.—Thirteenth day: Swelling of face extending; she cannot open her mouth.—Fourteenth day: Better; swelling less. A roseolous rash, papular on the extremities, but nearly a uniform blush over the right breast. Urine half albumen; contains blood and casts.—Fifteenth day: Bowels loose; rash all over body, large magenta papules, and irregular blotches.—Sixteenth day: Very noisy last night; a spreading bedsore has appeared. No pain. Sick once. Urine loaded with albumen; blood and casts.—Seventeenth day: Rash more brown. Vomit is thought to contain pus from the parotid swelling.—Eighteenth day: Restless, with perpetual vomiting. Parotid swelling very red and brawny. Two days later death occurred. Just before this the parotid swelling discharged freely into the mouth.—(Dr. Duncan: Martha Ward Books, vol. v., Case 54.)

CASE 13. *Traumatic peritonitis; no signs of pyæmia; parotitis; recovery.*—A young man fell off a bicycle, and a dray-wheel passed over his abdomen. Collapse; acute peritonitis. This was gradually clearing up when he became worse, with high temperature, slight delirium, and double parotitis. The swelling rapidly became very great; the skin was very red. Under belladonna lotion the swelling began to go down in thirty-six hours, and in a few days had disappeared. There were no other bad symptoms.—(Mr. A. Scott: Brighton Med. Chir. Soc., 1883.)

CASE 14. *Peritonitis; no signs of pyæmia; parotitis; recovery.*—A boy, aged twelve, was admitted into Guy's Hospital with acute general peritonitis, probably from abscess round the cæcum. After some days he had high temperature, delirium, and double parotitis. Both glands swelled rapidly, both suppurated, and were incised, with evacuation of pus. There were never any symptoms of pyæmia or septicæmia.—*(Ibid.)*

CASE 15. *Peritonitis from perforation; parotitis; death.*—A man, aged twenty-four, was admitted into the Middlesex Hospital on Jan. 4th, with acute peritonitis of a week's duration. He had a similar attack three years ago.—8th: Sudden pain in both parotid regions. Next day both glands were swollen and tender, and he could not open his mouth.—10th: Profuse sweating. Urine acid, no albumen.—14th: Left parotid swelling is discharging into the ear. Two drachms of pus let out by incision. Restless and delirious at night.—16th: Temperature 101·2°; pulse 128; respiration 44. Tongue dry and glazed. He looks wasted and apathetic. A purpuric eruption has appeared above the umbilicus, over the præcordia, and over the right breast. As there was some discharge from the right ear the right parotid was incised. No pus. Sweating; delirium; rapid rise of temperature to 104·8°; death.—*Necropsy:* Peritoneal abscesses, some of great size; signs of old peritonitis. The appendix opened by ulceration into a pelvic abscess.—(Dr. Finlay: Clin. Soc. Trans., 1885.)

CASE 16. *Peritonitis; parotitis; pyelo-nephritis; death.*—This is a post-mortem record of a case where parotid abscess was found conjoined with pyo-salpinx, suppuration in Douglas's pouch and around the rectum, acute pyelo-nephritis, with chronic interstitial nephritis, amyloid disease of liver and spleen, and pneumonia. The probable sequence of events is thus given: Rupture of the perineum; prolapse of the uterus; endometritis; pyo-salpinx with adhesions; escape of pus into subperitoneal tissue, followed by amyloid disease and septicæmia.—(Dr. Kingston Fowler: Med. Soc. Trans., vol. vii.)

CASE 17. *Bullet wound of lumbar spine; parotitis; pyæmia; death.*—President Garfield, shot on July 2nd, 1881. In August gastric irritation and vomiting set in. On the 17th the right parotid began to enlarge, and on the 24th it was incised; only a few drops of pus escaped. Later, it opened into the mouth and ear, and more incisions were made. In September, during intense heat, he had broncho-pneumonia, with great somnolency; then rigors, delirium, and prostration. Sudden death on the 19th.—*Post-mortem:* The bullet had broken the right eleventh rib, perforated the first lumbar vertebra, and become encysted behind the peritoneum, below the pancreas. Death from hæmorrhage from an ulcerated mesenteric artery. Very large abscess between liver and transverse colon. Signs of double bronchitis and broncho-pneumonia. One small abscess in left kidney. Parotid suppuration nearly healed.

CASE 18. *Malignant disease of lumbar spine: parotitis.*—A man, aged sixty, in the spring of 1885 was attacked by pain in the loins and lower extremities; it was constant,

Digitized by Google

with frequent exacerbations. He passed from under observation till his death on Oct. 8th, 1885. Post mortem, there was found a malignant tumour of the lumbar and sacral vertebræ, with secondary deposits, in liver, lungs, and bronchial glands. The kidneys were in the state called "surgical." There was an abscess in the subperitoneal tissue above the symphysis pubis and another in the substance of the right parotid.—(Mr. J. F. Macready. MS. case.)

CASE 19. *Peritonitis; abdominal section; parotitis; recovery.*—A man, aged twenty, fell ill with loss of appetite and severe abdominal pain, followed by vomiting and absolute constipation. Abdominal section revealed general peritonitis and a fetid abscess round the cæcum. The peritoneum was washed out, and the abscess was drained. Slight albuminuria a day or two later, followed by right parotitis. No suppuration; recovery.—(Dr. Barlow and Mr. Godlee: *Med. Times and Gazette*, Dec. 1885.)

CASE 20. *Peritonitis from perforation; parotitis; death.*—A man, aged twenty-six, had three weeks' paroxysmal abdominal pain, followed by jaundice about the eyes and vomiting. Exploration of right femoral hernial sac; gas and thin yellow fluid escaped. Sac stitched to skin and drained. His general condition now improved.—Fourth day after operation: A tender spot behind left angle of jaw.—Fifth day: Not so well; fever, loss of sleep, abdominal pain. Considerable swelling at both angles.—Sixth day: Death.—*Post-mortem:* Diffuse peritonitis; much pus in pelvis; a collection of bile-stained fluid near the duodenum, and a perforating ulcer of the anterior surface of the first part of it.—(Mr. Godlee: *Med. Times and Gazette*, May, 1885.)

CASE 21. *Gastric ulcer (?); parotitis; recovery.*—A lady, aged thirty-six, of feeble constitution, suffering from vaginitis, inflamed piles, and two small bedsores, suddenly showed symptoms of acute gastric ulcer; opium and nutrient enemata gave relief, but she was left in great mental and bodily weakness. Two or three weeks later the left parotid became inflamed and suppurated; a large abscess formed, and was opened in two places. This was followed by considerable left facial paralysis. She has never quite recovered her health of mind and body. The paralysis is less.—(Mr. C. T. Oldham. MS. case.)

CASE 22. *Gastrotomy; no signs of pyæmia; parotitis; recovery.*—A girl, aged seventeen, had in her stomach a matted mass of swallowed hairs, 2 lb. in weight. Mr. Thornton removed it by a transverse 5 in. incision through the stomach, and closed the wound with silk. There were no symptoms from either the stomach or the peritoneum; but in a few days one parotid swelled. It felt boggy, and was incised; no pus. Next day the other swelled, but subsided under belladonna and glycerine on wool.—(Trans. Internat. Med. Congress, 1885.)

CASE 23. *Gastrostomy; no signs of pyæmia; parotitis.*—A woman, aged forty-one, had for six months suffered from difficulty of swallowing. On Dec. 12th, 1884, the abdomen was opened, and the stomach was secured to the abdominal wall. — 20th: Stomach opened. — 22nd: Swelling in region of parotid. — 26th: Incised; about half an ounce of pus escaped. — Jan. 16th: Parotid wound healed. — Feb. 19th: Died of exhaustion.—No signs of general pyæmia.—(Mr. W. Bruce Clarke. MS. case.)

CASE 24. *Enterostomy; no signs of pyæmia; parotitis.*—A girl aged fourteen, after a fortnight's bad health, had fever, constipation, and vomiting. Urine 1030; no albumen or sugar. The vomiting became dark, then fæcal.—Feb. 7th: Abdominal section by Mr. Langton; enterostomy.—9th: Vomiting ceased; much relieved.—16th: Temperature has never risen above normal; she has slept and taken food well; has vomited once or twice; fæces have passed freely by the artificial anus. To-day a slight swelling of right parotid region.—18th: Goes on very well; temperature normal; parotid swelling rather larger. — 22nd: Urine normal. The parotid swelling has disappeared. General health good.—(Dr. Duckworth. Elizabeth Ward Books, St. Bartholomew's Hosp., 1886.)

CASE 25. *Abdominal obstruction; parotitis.*—This case is mentioned in Fagge's Principles of Medicine (i., 300). The obstruction was due to cancer of the sigmoid flexure.

CASE 26. *Cancer of sigmoid flexure; abdominal section; colotomy; parotitis.*—Emma T——, aged sixty; intestinal obstruction.—Jan. 4th: Abdominal section; puncture of cæcum; no peritonitis.—Jan. 7th: Obstruction still unrelieved; colotomy. Jan. 13th: right parotitis, which subsided in eight days. Death from the local disease.—(Mr. A. E. Barker: Univ. Coll. Hosp.)

CASE 27. *Herniotomy; parotitis; recovery.*—A man aged forty had a left inguinal hernia, strangulated twenty-four hours. Strangulation at both rings. Operation tedious; large piece of sac removed. Peritonitis followed, and he nearly died. On the third day after operation the left parotid swelled very suddenly. It subsided as suddenly, and in three days there was scarcely a sign of it. He recovered steadily. Something was being done to the drains at the time, but no bad smell was perceived.—(Mr. E. S. Dashwood. MS. case.)

CASE 28. *Removal of omentum; parotitis; pyæmia; death.*—A man had an omental tumour removed from a hernial sac. The operation was followed by pyæmia, of which the parotitis was a result. The case was in St. Bartholomew's Hospital some years ago, but the notes are incomplete.

CASE 29. *Acute jaundice; pyæmia (?); suppuration at angle of jaw; recovery.*—A man aged twenty-two, who had "some time previously" had gonorrhœa, with sore-throat, complained on March 7th of languor, headache, and weakness in legs.—11th: Vomiting; constipation; abdomen distended and painful; urine scanty, coffee-coloured, and albuminous.—13th: Marked jaundice, mental oppression, and pains in limbs. The thigh seemed swollen.—15th: The bowels well opened; urine scanty, but not albuminous. 18th: Vomiting ceased; less oppression; and pulse and tongue improved. — 20th: Continued improvement; less jaundiced. — 21st: Rash on the skin like urticaria. — 27th: Two or three days ago erysipelas of the right side of the face and neck came on, and suppuration occurred at the angle of the jaw; the abscess was opened.—30th: The erysipelas is disappearing, and he is recovering steadily.—(Dr. Habershon: Guy's Hosp. Rep., 1861.)

CASE 30. *Ovariotomy; parotitis; recovery.*—A multipara, aged thirty-two. Swelling of abdomen noticed since the last child. Punctured, and cystic fluid drawn off; feverish for some days.—Feb. 19th: Ovariotomy; evident peritonitis; the abdomen washed out with carbolic (1 in 100). She bore the operation well. No fever followed it. Four days later left parotitis occurred, with rise of temperature; a week later, right parotitis. Then the left parotid broke, and was freely incised. The right parotid also suppurated, and was incised. The temperature was highest early in the course of the parotitis, then it gradually sank.—(Professor Möricke: *Zeitschr. f. Gebürtshilfe und Gyn.*, v. 348.)

CASE 31. *Ovariotomy; parotitis; perimetritis; death.*—A multipara, aged forty-eight. Swelling of abdomen noticed five years. June 29th, ovariotomy; many adhesions. There was some fever next day, but it was gone by the sixth day. Then came a rise of temperature, with left parotitis. Five days later this was incised; a considerable quantity of pus was let out. The fever abated, but a week later there came fresh fever, with perimetritis; diarrhœa; bedsore; death on thirty-fifth day.—(*Ibid.*)

CASE 32. *Ovariotomy in an old patient; parotitis; death.*—A multipara, aged sixty-five; swelling of abdomen noticed three months. She is very feeble and wasted. Nov. 6th, ovariotomy; a large cyst with colloid contents, which had to be scooped out. No fever after the operation. Six days after it came slight rise of temperature, with swelling of right submaxillary and sublingual glands, followed by swelling of the parotid. Pus was seen issuing from Wharton's duct. Three days later the parotid was incised and pus let out. Fever; quick weak pulse. Swelling extended over neck. Death the same day. Operation wound healed by linear scar.—(*Ibid.*)

CASE 33. *Ovariotomy; parotitis; recovery.*—A strong, full-blooded woman, Frau S——. Swelling noticed two years. Much œdema of lower limbs. Oct. 20th, ovariotomy; strong adhesions, broad pedicle. No fever after the operation. Six or seven days later came painful swelling of right parotid. It all disappeared in six days.—(*Ibid.*)

CASE 34. *Ovariotomy; parotitis; abortion.*—A multipara, aged thirty-four; last child six years ago. Jan. 30th: Ovariotomy; two ovarian tumours were removed. Some rise of temperature for the first two days; she was then quite free from fever till the seventh day. Then came right parotitis, with some fever, and extension of inflammation over neck and face. This subsided, with a little subcutaneous abscess. Abortion followed. She is still under treatment.—(*Ibid.*)

Möricke's remarks on the last five cases are as follows. The patients had not been exposed to mumps, except in Case 30, and this was doubtful. Nor were their histories or their ages consistent with mumps. Their homes were

Digitized by Google

healthy. They did not infect each other. The parotitis was not due to pyæmia, for in all the cases there was a fever-free interval between the operation and the parotitis, and only one patient died with any symptoms like those of pyæmia. He has never seen parotitis after any other operation on the generative organs. In the interval between the primary lesion and itself, and in its rate of frequency after ovariotomy (1 in 50), this parotitis is very like the orchitis of mumps (1 in 60).

CASE 35. *Pelvic cellulitis; parotis; recovery.*—A primipara: aged twenty-two. On eighth day with pelvic cellulitis, double parotitis, which lasted only a week.—(Dr. T. Williams: Univ. Coll. Hosp.)

CASE 36. *Ovariotomy; parotitis: pus in left ovary; pyæmia; death.*—Miss E. W——, aged forty-nine. Strumous diathesis. First symptoms three years ago. June 18th: Ovariotomy; peritoneum darkly stained, containing a pint of very dark fluid. Appendices epiploicæ and intestines stained and injected, especially those near pelvis. Tumour broken up and removed (11 lb.). No grounds for anxiety during first week. She remained well till the eleventh day, taking solid food. All sutures removed.—28th: Slight swelling and stiffness in left parotid region.—30th: Parotid swelling more diffused.—July 2nd: Swelling very hard, with a red blush over it. Temperature 103°.—4th: Swelling hard and livid; no fluctuation. Furred tongue, thirst, and anorexia. Temperature 102·6°.—5th: Thin pus began to escape from the ear.—6th: Semi-comatose, with tremors of tongue and arms. Temperature 102° and 103·8°. Two small abscesses below lobe of ear incised.—7th: Temperature 105·4°. Death. —*Post-mortem:* Operation wound healed. Hæmorrhagic infarcts in lungs. Purulent pericarditis. Numerous abscesses of both kidneys. Left ovary cystic, filled with thick fetid purulent matter. Fetid pus escaped on pressure below lobe of ear; angle of jaw was denuded of periosteum. —(Dr. Bantock: *Med. Times and Gaz.*, Nov. 1878.)

I have ventured to add the foregoing case to the others, and to regard the parotitis as secondary to the suppuration in the left ovary or in the kidneys. Dr. Bantock speaks of it as due to primary otitis, and regards the suppuration in the left ovary as secondary.

CASE 37. *Pelvic abscess; parotitis.*—Catherine C——, aged fifty-four. Recurrent cancer of uterus; pain over pubes; no general peritonitis.—June 24th: Left parotitis.—July 3rd: Pus three ounces, let out.—15th: Peritonitis.—17th: Death. *Post-mortem:* Pelvic abscess; no general peritonitis; no signs of pyæmia.—(Dr. T. Williams: Univ. Coll. Hosp.)

CASE 38. *Ovariotomy; septic state already present; parotitis; death.*—The patient was bedridden and greatly wasted. Had been tapped twice, last time six weeks ago; grave septic symptoms had set in; "the operation was altogether a forlorn hope." Universal adhesions; death seemed imminent during and after the operation. Next day she had rallied, and for seven days she did fairly well, and the tube was removed. On the ninth day there were a slight rise in temperature and left parotitis. In three or four days the gland broke into the ear, and was also freely incised. "She had all the tokens of a mild septicæmia, from which she gave promise to get well: but her relatives were strict homœopaths, and objected to my medicine. So they took her home, where she died on the thirty-second day from vomiting, as I afterwards learned."—(Dr. Goodell, of Philadelphia.)

CASE 39. *Ovarian tumour; removal; parotitis; recovery.*—Miss ——, aged twenty-seven; ascites for two years and a half; tapped fourteen times. A hard swelling to be felt floating in the abdominal cavity.—April 18th: Operation; removal of a hard nodular papillomatous tumour of right ovary.—21st: Swelling of both parotids; barely any rise of temperature; rapid recovery. The tumour had merely omental adhesions, and a long, slender, twisted pedicle. "The ascitic fluid was evidently secreted directly from the tumour, and did not come from pressure on abdominal veins or from irritation of the peritoneum."—(*Ibid.*)

CASE 40. *Oöphorectomy; parotitis; recovery.*—Mrs. ——, aged twenty-one, invalid for several years, bedridden for six months with constant pain. Left ovary enlarged and very painful; morphia habit.—Sept. 17th: Both ovaries removed; left hypertrophied and cystic.—21st: Painful swelling of right parotid; left parotitis a few days later. No marked rise of temperature; no quickening of pulse; not the slightest evidence of septicæmia. "Sympathetic, not symptomatic"; exactly like mumps, but slower to disappear.—(*Ibid.*)

CASE 41. *Operation for lacerated cervix; parotitis; recovery.* There was hæmorrhage almost immediately after the operation; the patient lost a great deal of blood, and was much weakened. Convalescence slow, but no trace of fever. In the second week parotitis came on, first of one side then of the other. The submaxillary glands also became tender and swollen. The glands slowly subsided; she then for some time had hysterical trismus.—(*Ibid.*)

Dr. Goodell has very kindly sent me his account of the last four cases. It will soon be published in the *American Journal of Obstetrics*. Case 39 is already reported there, vol. xvi., p. 744. He also refers to *Annales de Gynæcologie*, Aug. 1885, and to the two cases of Dr. Macdonald.

CASES 42 to 52.—These ten cases were mentioned in the discussion on Dr. Goodell's paper at the American Gynæcological Society last autumn. Dr. Sutton referred to a case in which one gland after the other began to swell during convalescence after ovariotomy, the patient dying during the third week. Dr. Johnson reported a case of swelling of both parotids after ovariotomy, which ended in death on the ninth day. Dr. Mann related three cases. One of these ended in death with septic symptoms; another recovered; both were ovariotomies. The third was a penetrating wound of the abdomen. It recovered. Dr. Emmett gave two cases: one after operation for lacerated cervix, with recovery; one after operation for a small vesico-vaginal fistula, with death. Dr. Baker gave a case after Tait's operation. The gland suppurated and death ensued. Dr. Reamy gave two cases: one after Tait's operation, with death; one after hysterectomy, with recovery.—(*Med. Times and Gaz.*, Dec. 26th, 1885.)

CASE 53. *Abdominal section; parotitis; recovery.*—Mrs. S——, aged fifty. Large retro-peritoneal tumour removed by abdominal section, together with left kidney, to which it adhered. Eleven days later, right parotitis, which was incised and drained. No signs of pyæmia.—(Mr. Hulke: Middlesex Hospital.)

CASES 54 and 55. *Ovariotomy; parotitis; recovery.*—Mrs. D——, aged fifty-two. Swelling noticed seven months. June 28th, ovariotomy. Adhesions in front, and to the omentum. Pedicle broad and thick. Left ovary healthy. Eight days later intense parotitis, lasting for about a fortnight. Recovery otherwise uninterrupted. "This is the second time I have met with parotitis after ovariotomy. In neither of these cases was there temperature or other symptoms to lend the least colour to the opinion that the parotid inflammation was septic. In neither case did the glands suppurate. The parotitis merely complicated the convalescence a little by the pain and slight fever it induced." Dr. Macdonald refers to a case of parotitis after ovariotomy for a burst cyst in the *Centralblatt für Gynäk.*, 47, 1884.—(*Edin. Med. Journ.*, May, 1885.)

CASE 56. *Incision of cervix uteri; parotitis.*—Dr. Matthews Duncan told me of this case, which occurred in the practice of Sir James Simpson. The inflammation was very severe, and of both glands. It subsided rapidly, without suppuration.

CASE 57. *Repeated parotitis with each pregnancy.*—Mrs. M——, aged forty-three, tall and thin. During six successive pregnancies she has had enlargement of the left parotid. "She has learned to recognise this as one of the first indications of her condition." It increases with the advance of gestation and disappears after delivery.—(Dr. Harkin: THE LANCET, Feb. 1886.)

CASE 58. *Use of a pessary; parotitis; recovery.*—A lady, aged sixty, had bearing-down pains; uterus rather low down. Hodge pessary introduced without much pain. On her way home, pain and faintness. Four days later, pain in the back, tremor, dry tongue, pulse 120, temperature 104·5°; left parotid region swollen and painful. Shivering fit the day before. The day after, less fever, less pain, less swelling. Next day, slight vaginal discharge; pessary therefore removed, though not causing any discomfort. She soon got well, and remained well, even after the re-insertion of it.—(Dr. Cribb: THE LANCET, Jan. 1886).

CASE 59. *Amenorrhœa; parotitis at menstrual periods.*—(Stéphanie, v. 23.) In May, parotitis. In June, parotitis. In July, swelling of the labia. In August, parotitis. In September, parotitis. In October, menstruation; no swelling of parotid or labia. In November, swelling of the labia. The parotitis was always on the left side.—(Prof. Peter: *Gaz. des Hôp.*, 1868, p. 146.)

With this case may be compared a passage in Dr. Goodell's paper: "I am now treating two ladies for nerve exhaustion. One has excessive salivation just before and durin

Digitized by Google

menstruation; in the other, who has a congested and tender left ovary, the left parotid gland does not secrete during menstruation, and then the mouth and fauces on that side are dry and painful."

CASE 60.—Billroth, among his Zurich cases, had one of parotitis after a blow on the testicle.

STONE SACCULATED IN THE BLADDER OF A FEMALE.

BY CHAS. WILLIAMS, F.R.C.S. ED.,
SURGEON TO THE NORFOLK AND NORWICH HOSPITAL.

CASES in which a vesical calculus is impacted in a cyst situated in the walls of the bladder are so extremely rare, that I consider it a duty to record this very interesting example.

A fine and healthy girl, aged three years, living in Norwich, came under the care of the late Mr. George Hutchison in the year 1873, having for several months previously suffered from very decided symptoms of stone in the bladder. It had been noticed by her mother that from the time of her birth she had experienced a difficulty, as well as occasionally severe pain in passing urine, and that sometimes she voided blood mixed with it, and was in the habit of straining so violently as to produce prolapsus of the rectum.

On sounding the bladder, which was an unusually capacious one, it was with some difficulty that a calculus could be detected. At the wish of the parents Mr. Hutchison resolved to remove the stone by dilatation. Mr. W. H. Day assisted at the operation, and I was requested to administer chloroform. The urethra was freely and quickly dilated with Weiss's trivalve dilator. There was considerable trouble to find the stone, and when found a still greater trouble to seize it with the forceps (and it was particularly noticed that, although the patient was thoroughly under the influence of the anæsthetic, the getting hold of the stone with the forceps occasioned severe straining); the blades could not be made to grip the calculus; they continually slipped off, bringing away pieces of the stone. At last it became absolutely necessary to ascertain what occasioned the difficulty. For this purpose the urethra was still further dilated, and the neck of the bladder was also divided with a probe-pointed bistoury. The stone could now be felt with the point of the finger immovably fixed in the floor of the bladder on the patient's left. It appeared to be of the size of a pigeon's egg, and was enclosed in a sac, through the neck of which a small portion protruded into the vesical cavity, and it was off this nodule that the forceps so continuously slipped. Many efforts were made to dislodge it—first with a scoop, then with the finger, which could barely reach it, and next with the forceps; they all proved unsuccessful. Several portions were broken off the uncovered portion, but the main piece was left *in situ*, as it was considered undesirable to make any further attempt to remove it, the patient having been a long time under the influence of chloroform and apparently in a very exhausted condition.

The next day the child had voided very little urine. A catheter was introduced, and a small quantity of sanguineous urine flowed out. She was very drowsy, and had been so since the operation. When roused she took milk and brandy very freely, but immediately afterwards became drowsy again; she did not appear to have recovered from the influence of the chloroform. The next day she died. No post-mortem examination was permitted.

I am induced to believe this child died of chronic chloroform-poisoning, and not from the effects of the operation, which was by no means roughly performed, and there was very little blood lost. She never thoroughly revived, but became comatose, and died in that condition. It is difficult to imagine what could have given rise to the formation of the sac; there never was an obstruction to the escape of the urine, such as stricture or prostatic enlargement might engender, for neither existed. We are taught that a cyst is usually formed by the straining necessary to expel the urine; the mucous membrane is forced between the bands of muscular fibres, hypertrophied in consequence of the strain to which they are subjected. Nothing of the sort can apply in this case, and it is not easy to believe that the stone was the cause of the cyst, which it might have been had it been situated close to the neck of the bladder. When impacted in this situation, the very pressure to which a stone is subjected by the constant and long-continued action of the bladder to expel it causes the mucous membrane to ulcerate through, and the stone is in due time forced into a cavity, which enlarges as the stone grows, and in this way it may form a tumour in the vagina, as was the case reported by me in THE LANCET of Nov. 7th, 1885. An effort is then made by nature to contract the opening, which in this child was nearly accomplished; but the calculus was far from the neck of the bladder, and could barely be touched with the point of the finger, so that a different explanation of the formation of the cyst is required; and as no examination was allowed to be made, it seems to me to be almost impossible to suggest in what way the sac was formed. Sabulous matter or a few urinary crystals may probably have been deposited originally in a mucous follicle, lacuna, or fossa, and gradually augmented in quantity, and in this way the sac enclosing the calculus may have been produced. The mother of the girl at four years of age suffered from stone, which was removed by the late Dr. Edward Lubbock; it was the size and shape of a walnut. She has suffered from incontinence since that time.

IMPERFORATE RECTUM TREATED SUCCESSFULLY BY LEFT INGUINAL COLOTOMY.

BY HUGH STOTT, M.R.C.S., L.S.A.L.

A CASE of imperforate rectum was recently brought under my care. The subject was a small but full-time infant four days old; it was an illegitimate child. The mother had noticed that the baby had not passed a motion since birth, and that it was constantly sick, the vomit being of a yellow colour, of a strong odour, and staining the clothes. The mother at the birth of the child was attended by a midwife. The rectum, on examination, disclosed a natural opening for the anus, and on passing a bougie made of soap up the canal it was arrested at the second inch; by carefully inserting the little finger no bulging of bowel or any indication of such could be made out. I therefore resolved, instead of dissecting up and seeking the end of the bowel, to perform left inguinal colotomy or Littré's operation. For this purpose I gave chloroform, and made an incision above Poupart's ligament in the left groin, about two inches in length, in a curved direction upwards towards the anterior superior spine of the ilium. Upon opening the peritoneum a quantity of yellow-coloured fluid exuded, and the large bowel bulged forwards; this was pushed upwards until the lowest part was reached. It had no free end, but was attached. The bowel was stitched on either side of the edges of the wound and then opened between the stitches. Some meconium escaped; there was little or no bleeding. The wound was dressed with strips of lint saturated with carbolised oil (1 in 100), a loose pad of cotton-wool, and then a bandage. The child recovered from the chloroform and was not sick; it was put to bed with its mother, and took from the bottle cow's milk and water. The stitches, which were silk, were removed on the third day, and the wound healed kindly, without any sign of suppuration, which is to be wondered at considering the wretched and dirty state of the surroundings. The child is now three months old, and is thriving; the wound has perfectly healed, and looks clean and healthy; at present there is no prolapse of bowel. The operation was done by myself without assistance, except that an old woman looked on. This will show the simplicity of the operation.

Perhaps the question may be raised, Was it right to endeavour to prolong this child's life? It has been said in such cases, "Let the child die," but I strongly agree with Mr. T. Holmes, who says, in reference to these cases, "A surgeon who would not operate in a case of this kind would, I think, neglect one of the plainest duties of his profession." Is a surgeon to arrogate the power as to whether a person shall live or die? As to the choice of operations, I selected Littré's: first, because it is easier to do without assistance; and, secondly, because contractions following a dissection upwards in the course of the rectum are so liable to take place, leaving the patient probably in a worse state than he was before. It may be I shall later on endeavour to establish a natural discharge for the fæcal matter at the anus.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

SARCOMA OF BLADDER; CYSTOTOMY; SUPRA-PUBIC PUNCTURE.

(Under the care of Mr. MORRANT BAKER.)

IN the case which is here recorded operative surgery could afford only palliation. It is an example, however, of how much relief may be given in certain cases of malignant disease of the bladder, even under circumstances the most unfavourable. The total duration of life after the patient's first admission into the hospital was not much more than four months, but about half of this period was rendered free from acute pain and distress by the performance of the operation, and for some weeks the patient felt comparatively well. For the notes of the case we are indebted to Mr. Vogan, late house-surgeon.

J. S——, aged fifty-five, a harness-maker, was admitted to Darker ward on Sept. 11th, 1884. About six months ago he felt a smarting pain when micturating. Two weeks previously he had noticed blood in his urine and smarting pains at the tip of the penis both before and after micturition. He now has great pain about the loins, which shoots down the thighs, and frequent desire to micturate. No history of syphilis, gout, or rheumatism. Urine: sp. gr. 1026; alkaline; blood and albumen present, but no sugar. Examined per anum, the prostate was not noticeably enlarged, but felt a little firmer and more prominent on the left than on the right side, but the difference was not more than might be accidental. Examined by sound, no stone could be detected, but some hard substance was struck.

Sept. 23rd.—Pain in loins continues, also that referred to end of penis; there is also pain on defecation. He cannot hold his urine for more than two hours and a half, and has to strain to pass it.

26th.—Bladder washed out with syphon apparatus, which gave him some relief.

Oct. 6th.—There is not much blood in the urine, but on passing a catheter directly after micturition about two ounces of bloody fluid were drawn off. Pain referred to sacrum.

9th.—The urine on examination under the microscope was found to contain blood-corpuscles, pus-corpuscles, and bladder epithelium, but no portions of new growth were seen. He can only hold his water for an hour and a half at a time, and has more pain on passing it and on defecation.

11th.—The patient was taken into the operating theatre and anæsthetised, and Mr. Baker made a median incision in the perineum. On passing his finger into the bladder, a growth was felt about the size of a small Tangerine orange, having a large and firm base, though somewhat constricted. It was situated behind and slightly to the right of the prostate. Several pieces, each about the size of a filbert nut, were removed with Sir Henry Thompson's crushing forceps. The base was then felt to infiltrate the walls of the bladder, which were adherent to the surrounding tissues. Hæmorrhage was rather free during the operation and for about one hour afterwards.

12th.—Slept well and feels easy. The pain in the bladder is much less than before the operation. Temperature 100·4°.

25th.—Got up after tea yesterday. Rests at night much better than before the operation, and has no pain except during and for a short time after micturition. Very little blood in the urine, which nearly all passes through the penis.

Nov. 7th.—On examination per anum, a large swelling was felt in the region of the prostate; it was exceedingly tender. The patient has lately complained of pain in the hypogastric region.

11th.—Discharged from hospital. All the urine passes per urethram. Hardly any blood in the urine, but rather more pain has been complained of lately, both at the time of and after micturition and defecation. The patient has been greatly relieved by the operation.

29th.—Readmitted, suffering from recurrence of severe pain and other symptoms, as on the former occasion. At the present time there is just in the scar of the operation in the perineum a hard tumour the size of a horse-chesnut. The hypogastrium is tender, and a fulness in the region of the bladder is very distinct.

Dec. 12th.—The bladder has been washed out twice a day with warm boracic acid lotion, which gives him some relief. The temperature varies from below normal to 102·4°. The difficulty and pain in passing the catheter are increasing. The tumour in the perineum has rapidly increased in size during the last week, more especially anteriorly and in the direction of the left crus penis. It is also encroaching on the wall of the rectum. During the last few days a hard swelling has appeared on the right side of the penis about its centre. Passes urine every three-quarters of an hour.

13th.—The patient was anæsthetised, and after examination Mr. Baker decided not to perform any further operation for the removal of the growth, this having extended to the rectum and involved nearly the whole of the perineum.

19th.—The swelling on the right side of the penis has disappeared, but that in the perineum has partially broken down.

Jan. 1st, 1885.—This afternoon Mr. Baker made a supra-pubic puncture into the bladder and introduced through the wound a soft red-rubber catheter. A long piece of india-rubber tubing was attached to the end of the catheter, so as to conduct the urine to a utensil under the bed and allow of continuous drainage.

2nd.—Patient very much relieved by the operation.

16th.—For some days the patient has requested that the catheter should be removed, saying that it gave him pain. It was removed to-day, and a pad of absorbent wool kept over the wound.

19th.—The patient has been gradually sinking, and died at 11 o'clock last night.

Necropsy.—There were two small sarcomatous nodules in the right pleura, and two similar nodules in the liver. The bladder was filled, except at its upper part, by a new growth that infiltrated its anterior and lateral walls as well as the fundus, and had a cauliflower-like form. By the backward extension of the tumour the rectum had become fixed and surrounded, and close to the anus the growth had sprouted into the gut, and by breaking down had established a recto-vesical fistula. The ureters were a little distended, and their orifices into the bladder partly occluded by the growth. The renal pelves and calyces were dilated. The left renal pelvis contained fetid pus.

ROYAL BERKSHIRE HOSPITAL.

A CASE OF SUBACUTE MYELITIS, WITH CALCULUS IMPACTED IN THE URETER; REMARKS.

(Under the care of Dr. H. FRENCH BANHAM.)

S. J——, aged thirty-eight, was admitted on Nov. 10th, 1885, and died Jan. 4th, 1886. On examination there was found to be complete loss of motor power in the legs, and all sensibility to touch or temperature was annulled. There was also absolute paralysis of bladder and rectum. The bladder was enormously distended, and formed a considerable tumour, so large as to arrest the attention on reaching the patient's bedside. The urine was withdrawn by the nurse, but the quantity was not measured. The knee reflexes were intact, but the plantar and hypogastric superficial reflexes were absent. Bedsores already existed over the upper part of the nates. Pain in the back, which seemed to have troubled the patient a great deal before admission, still existed, but was chiefly in the dorsal region. There was more or less complete anæsthesia over the abdomen as far as the umbilicus, and although she was troubled with the girdle sensation, there was not found here any hyperæsthetic zone. The patient was possessed of less than average intellect, and it was difficult to determine how much reliance could be placed upon her statements in regard to the previous history of her illness. It would seem, however, that an uncertain amount of pain in her back and legs had characterised the early part of her illness, and that the paraplegia with loss of control over the sphincters had been preceded by perverted sensations and numbness, if not by complete anæsthesia. The anæsthesia

Digitized by Google

over the abdomen was soon found to vary a good deal from day to day, and to be irregular in its distribution. Within a few days of admission she began to be troubled with severe muscular spasms, by which the legs were flexed upon the abdomen. The urine soon presented an alkaline reaction with abundance of ropy mucus—the usual indications, indeed, of a pronounced cystitis. Without going into particulars with regard to the treatment adopted, it may be said that all efforts, general and local, directed to the relief of the spinal trouble, the cystitis, and the bedsores, were unavailing, and a downward progression marked the course of the disease, and the patient died on Jan. 4th.

Remarks by Dr. BANHAM.—The circumstances were unfavourable to a complete and thorough post-mortem examination, and the spinal cord unhappily was not examined. It will, however, be conceded that paraplegia, with absolute anæsthesia, loss of control over the bladder and rectum, and bedsores over the sacrum, form a group of symptoms that, taken collectively, render the existence of myelitis not probable only, but certain; and it may be said that such a condition was present. In addition to the myelitis, there was an impacted calculus in the ureter, which above was distended and thinned, while the pelvis and kidney were in the morbid condition that constitutes what is known as "surgical kidney." We have, therefore, in this case the coincidence of two diseases of sufficient rarity to justify the suspicion of a causative relation existing between them. The calculus and the alterations that the kidney and ureter had undergone indicate clearly that disease in these parts had preceded the spinal symptoms, which, indeed, only came on within three months of the final issue. It seems probable that there was a subacute transverse myelitis, which, commencing in the lower part of the spinal cord, ascended and became converted into a meningo-myelitis, all secondary, and due to an impacted calculus in the ureter. From a comparison with other similar cases that have been recorded, and that have been the subject of careful examination, there can be no doubt that the spinal cord lesion in this case was consecutive to a neuritis which travelled upwards from the irritation in the kidney and ureter.

CASHEL UNION HOSPITAL.

LARYNGOTOMY; RECOVERY.

(Under the care of Dr. LAFFAN.)

THE following case of successful laryngotomy may prove interesting from the encouragement which it holds out to prompt action in like emergency. Dr. Laffan knows of cases where life has apparently been lost from want of operative measures in similar circumstances.

M. N——, farm labourer, aged fifty-three, was admitted at 4 P.M. on July 30th, 1885. He complained of sore-throat and had some slight difficulty of breathing. On examination signs of an ordinary attack of pharyngitis presented themselves. The uvula was more swollen than usual; but to this much significance was not attached. Therefore some routine treatment was ordered, and he was sent to one of the wards. An hour had scarcely elapsed when Dr. Laffan was hurriedly sent for, with the announcement that the patient was dying. In about ten minutes he was found suffering from such extreme dyspnœa as to promise speedy asphyxia. The imminence of his danger was explained to him, and his permission obtained for operation. The larynx was at once opened through the crico-thyroid membrane; there was scarcely any bleeding, and a dilating tube was easily inserted. At the moment of operation he fell back apparently dead, but the entrance of air into the chest, a subcutaneous injection of ether over the sternal region, and ammonia to the nostril quickly revived him. Notwithstanding that every possible precaution was taken, such as regulated temperature, hot steaming, &c., the patient was seized with pleuro-pneumonia of the right base twenty-four hours after the operation. Fourteen days after this he was attacked with pleuro-pneumonia of the left side, and it was not till after the lapse of five months that he recovered perfectly. He was detained in the hospital some time longer, as his family circumstances were poor, and Dr. Laffan was anxious to avoid exposing him to the hardship incidental to a damp house and scant living. The tube was maintained in for eight days only, and the wound healed a few days afterwards.

The pain which ushered in the inflammation of the right lung was situated so near where the ether was injected that it was thought not impossible that there might be some connexion between the two; and when the second lung was seized it followed immediately on the opening of a small abscess, which formed at the point of injection. Dr. Laffan would prefer to select the arm or leg for the seat of injection on another occasion.

STRANGULATED FEMORAL HERNIA; ASPIRATION, FOLLOWED BY TEMPORARY RELIEF; OPERATION; FÆCAL FISTULA; DEATH FROM PHTHISIS; REMARKS.

M. L——, a female, married, aged fifty, was admitted on July 30th, under the care of Dr. Laffan, with strangulated right femoral hernia. The history was that she had had a rupture for twelve months, and that this had doubled in size and become very painful about two days prior to her admission. Taxis had been tried by the previous surgeon, and was consequently now only slightly attempted. There was severe pain, but no great constitutional disturbance. She declined to allow a cutting operation, and Dr. Laffan then resolved to give tapping with the aspirator a trial. A small trocar and cannula were employed. Some fluid bowel contents came away; the bowel became readily flaccid, and slight pressure caused it to disappear altogether; this it did, however, without gurgle. Next day the tumour reappeared to the extent of half its former size. It was much softer, and some fluid matter exuded on pressure. On Aug. 1st she was attacked with severe pain in the part. On the 2nd she consented to be operated on. This was accordingly done about 6 P.M. A portion of the anterior wall of one of the coils, about the size of a florin, was found to be gangrenous, and in it there was a small opening, produced by the aspiration needle. Some of the adjacent portions of bowel presented marked signs of inflammation. Constant vomiting followed. This was checked after some hours by drop doses of aromatic ammonia. There was some abdominal swelling, with a pulse of 112 and a temperature of 99·8°. There was some local tenderness, but it scarcely amounted to pain, and no general peritonitis at any time set in. A fæcal fistula ultimately formed. The discharges from the fistula were frequent during the day, and as it was high up in the small intestine, these weakened her very much. An effort was made to compensate for these by injections into the distal end, but these would not be tolerated by the part. An attempt to close the fistula by pressure, and another to restore the continuity of the bowel for temporary digestive purposes by means of a flexible tube, likewise proved failures. Pancreatic enemata were administered per rectum, and these helped to sustain the system to a certain extent. Dr. Laffan was arranging for an attempted cure of the fistula with Dupuytren's enteretome, when the recrudescence of a chronic phthisis set in, and finally disposed of the patient on Sept. 16th.

Remarks by Dr. LAFFAN.—There are two points in this case worthy of note. The first is the unreliability of the treatment by the aspirator, since by the seeming return of the tumour which followed from it, it tended to mask the real state of things. Absence of gurgle in the case of an unemptied gut would be significant enough, but in that of an emptied one might mean nothing, and could not therefore afford the help which it would in the case of an untapped bowel. The second point is the hint afforded by the continued, though very small, discharge of intestinal contents. This in itself I shall in future regard as an almost certain sign of gangrene, as I know of no instance where structures not gangrenous have failed to close up after the use of a small trocar, No. 3 of the most improved form of aspirator.

ST. JOHN AMBULANCE ASSOCIATION.—The third annual meeting of the Gibraltar Centre was held on the 31st ult., at the new Assembly Rooms. The Governor, his Excellency General Sir John Adye, G.C.B., presided, and Lady Adye presented certificates and medallions, among the recipients of the latter being the Chief Justice, Sir H. J. Burford Hancock. Brigade Surgeon A. Clarke has reported to St. John's Gate an excellent case of first aid rendered by Gentleman Cadet H. R. Beddoes, now attending his lectures at the Royal Military College. A poor woman was knocked down by a train at Farnborough Station and had her foot and leg smashed. There was profuse arterial bleeding and much shock. No surgeon was available, but Mr. Beddoes applied temporary tourniquets and took such other measures as undoubtedly saved the woman's life.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Chemical Pathology of Respiration in Cholera.—Splenectomy.

AN ordinary meeting of this Society took place on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the Chair.

Mr. WILLIAM SEDGWICK read a paper on the Chemical Pathology of Respiration in Cholera. After some introductory remarks on cyanosis in relation to choleraic collapse, the author referred to the early observations of Dr. John Davy and Mr. Finlayson on the absolute reduction of carbonic acid in the air expired by cholera patients in Ceylon during the epidemic of 1819; and to those of M. Rayer on the absolute reduction of oxygen absorbed in the cases observed by him in Paris during the epidemic of 1832. Such observations proved simply that the pulmonary interchanges of gases was diminished; whilst those of M. Doyère, made during the epidemic of cholera in Paris in 1849 and 1854, demonstrated that the amount of oxygen absorbed, although absolutely diminished, was relatively much larger than the amount of carbonic acid eliminated, and was always above the standard proportion observed in the interchange of these gases during health. Attention was directed to the absence of any unsatisfied demand of the blood for oxygen; to the failure of the voice common to cholera, and to gastro-intestinal cases simulating cholera; and to the influence of the disease on the dyspnœa of phthisis. The contraction of the lungs observed after death during collapse resulted from absence of blood and of air, and was referable to diminished supply of carbonated blood during life. Percussion during collapse, as was first shown by Professor Griesinger, gave, in consequence, a small area of cardiac dulness. The relative excess of oxygen accounted for the integrity of the mental faculties, for the contracted state of the left ventricle after death, and for the emptiness of the brachial and other large arteries which has been observed during advanced periods of collapse. As carbonic acid was a lower compound than urea, the production of the former was greatly diminished, whilst that of the latter was stopped, during well-marked collapse. Owing to the reduced production of carbonic acid there was diminished animal heat during collapse, whilst the rise of temperature, which occurred before and also after death, was dependent on the accumulation of previously unconsumed oxygen.—Dr. B. O'CONNOR asked for a fuller explanation of the rise of temperature immediately preceding and following death. He did not gather whether the accumulated oxygen combined with carbon in the production of carbonic acid and the development of heat, or whether there was some other method by which heat was liberated.—Mr. SEDGWICK considered, in reply, that the accumulated oxygen combined with some combustible substances when the vital influence was removed. It was the first occasion on which the chemistry of collapse had ever been brought before the notice of any medical society in this country. During hibernation the oxygen absorbed was almost double the amount of carbonic acid eliminated, a condition which had some analogies with the chemical changes in collapse.

Mr. KNOWSLEY THORNTON read a paper on two cases of Splenectomy. This paper contained a detailed record of a case of splenectomy for cystic spleen in a girl of nineteen. The pedicle was ligatured with silk and the ligatures cut short. The operation was performed with full antiseptic precautions. The patient made a complete recovery and is now in much better health than before the operation. Another case of splenectomy for hypertrophy of the spleen was also related. In this case there was retraction of a small artery from the middle loop of the three ligatures, with hæmorrhage into the omentum and remarkable general oozing, and cyanotic condition of the patient, who apparently rallied from the operation, but died from internal hæmorrhage in five hours and a half. Tables of eleven successful and twenty-three unsuccessful splenectomies, with four successful partial splenectomies, were appended, with remarks on the causes of success and failure. All the cases in which leukæmia was present were fatal, and operations under these circumstances are, the author contends, unjustifiable. Credé had collected most of the cases in a paper in Von Langenbeck's *Archives*. Splenectomy for hypertrophy of the organ was not so favourable for operation as wandering spleen or cystic disease of the organ. In reply to the President, he said Mr. W. Haward's case had been included in the table; it happened in 1881, and was one of leukæmia. So far as he knew, the girl was now in a good state of health and menstruating normally; as a house and parlour-maid she was performing a fair amount of hard work. In one of the successful cases the woman bore a child after the operation. In another case the woman was in good health nine years after splenectomy.—Dr. A. MONEY said that, in animals, after removal of the spleen a fresh formation of splenic tissue was said to occur in the neighbourhood of the original spleen.—Mr. THORNTON said that the running powers and appetites of animals were increased after experimental splenectomy; it was interesting to observe that in his successful case the girl acquired an enormous appetite.—Mr. BRUCE CLARKE inquired if any reason could be assigned why cases of leukæmia should prove so unfavourable for operation.—Mr. G. D. POLLOCK had made a necropsy on a case some years ago in which the spleen was two feet in length and of enormous dimensions; death took place apparently from simple exhaustion.—Mr. K. THORNTON, in reply, considered that leukæmic patients would not bear any surgical operation well; the blood coagulated with great difficulty, and there was a proneness to hæmorrhage.—This last fact was illustrated by a case, narrated by the President, of a man who died two days after a large hæmorrhage into the legs.

CLINICAL SOCIETY OF LONDON.

Erythema Nodosum and Rheumatism.—Peculiar Cases of Pneumothorax.—Lithotapaxy in a Boy of Ten.

AN ordinary meeting of this Society was held on the 9th inst., Mr. Bryant, F.R.C.S., President, in the chair.

Dr. STEPHEN MACKENZIE read a paper on Erythema Nodosum, especially dealing with its connexion with Rheumatism. The paper commenced with the narration of the case of a young woman who was admitted into the London Hospital with erythema nodosum. Whilst under treatment for this, symptoms of a moderately severe attack of acute rheumatism developed, with doubtful signs of heart affection. Two slight relapses of the rheumatic symptoms occurred. The discrepant statements of writers on the subject are well known, and the occurrence of this case led the author to collect data for forming an opinion as to the connexion between erythema nodosum and rheumatism. By the assistance of Drs. Hadden, Carrington, Arthur Davis, and James Anderson, particulars of 108 cases of erythema nodosum were collected from the records of St. Thomas's, Guy's, St. Bartholomew's, and the London Hospitals. Analysis of these cases gave the following facts: There were eighteen males and ninety females, or five females to one male. The greatest incidence of the disease was found to occur in the second and third decennia, next in the fourth and first decennia, whilst few occurred in and after the fifth decennium. The age incidence is very similar to what occurs in rheumatism. In seventeen cases, or 15·7 per cent., there were present well-marked symptoms of acute or subacute rheumatism. In four of these cases the rheumatism was stated to have preceded the erythema, in two the erythema preceded the rheumatism, in two the erythema and rheumatism appeared concurrently, and in the remainder the sequence was not recorded. Besides these cases, there were seventeen others in which arthritic pains were present, apparently distinct from the pain in the limbs in which the eruption was present. In three of these there was a history of previous rheumatism, in four there was evidence of heart disease or disorder, besides sore-throat in the attack in two, and a family history of rheumatism in two. Though the evidence of the rheumatic nature of these last seventeen cases is not so strong as in the first seventeen, the author believed that they ought really to be included in the rheumatic category. If this were done it gave 17 + 17 = 34, or 31·4 per cent., with symptoms of rheumatism occurring with erythema nodosum. Further, in twelve cases in which no rheumatic symptoms accompanied the attack of erythema the patient had previously suffered from rheumatism. In six cases recurrences were noted. In one case the patient died in the sixth attack of acute rheumatism, and had erythema nodosum with three of the attacks. Sore-throat (including two cases

Digitized by Google

of tonsillitis), which so often precedes and accompanies acute rheumatism, was present in twelve cases—though not specially inquired for; and in eleven cases there was a family history of rheumatism. A matter of great importance in establishing the connexion between erythema nodosum and rheumatism is the condition of the heart. Some important evidence was given. In twenty cases some definite lesion was present; ten of these are included in the group of cases in which rheumatism accompanied the attack of erythema; but in ten others, and three doubtful lesions, there was no arthritis accompanying the attack, though in some there had been previous rheumatism. Most important of all was the fact that a heart lesion, presumably endocarditis (with in one case pericarditis), developed in five cases during the attack of erythema nodosum. In three of these there was accompanying affection of the joints, whilst in two the joints were not affected in the attack. The author submitted that these facts justified the following conclusions:—1. That erythema nodosum is frequently associated with definitely rheumatic symptoms—e.g., arthritis, sour sweats, sore-throat, &c. 2. That heart disease (endocarditis) may arise during an attack of erythema nodosum, both in cases in which arthritis is present and in cases in which there is no affection of the joints. 3. That these conclusions justify the inference that erythema nodosum is frequently, if not generally, an expression of rheumatism, even when no other definitely rheumatic symptoms are present.—Dr. S. WILKS alluded to the connexion of rheumatism with erythemata generally, remarking that the nomenclature had been materially altered of late years. With regard to some of the cases quoted by Dr. Mackenzie, there might be some doubt as to their being rheumatism. In blood-poisoning of many kinds, affection of joints and rashes were met with, and yet the cases were not rheumatism. He was sometimes in doubt which was the more important, the rash or the arthritis. The so-called purpura urticans was sometimes associated with slight joint affection, so that he had considerable doubt as to the nature of some of such cases; by the older observers the skin diseases might have been regarded as the essential elements, the joint pains and fever being looked upon as manifestations of the cutaneous lesion.—Dr. CARRINGTON spoke of the connexion between erythema nodosum and heart disease; the existence of systolic apical murmur was not certain evidence of endocarditis.—Dr. S. WEST said that the relative frequency of heart disease in acute rheumatism was about 50 per cent.; in erythema nodosum but a few per cent. He thought that cases of erythema nodosum were only occasionally coincident with acute rheumatism.—Dr. RADCLIFFE CROCKER discussed the nature of the connexion between the arthritic pains and the erythemata; a nervous or local mechanism might be suggested; the rash was frequent in the neighbourhood of painful joints. In a case of simple synovitis of one knee a single patch of erythema papulatum was also limited to the joint. This suggested a direct local connexion, the eruption being due to the joint changes rather than to some profound blood lesion. Whilst he regarded erythema nodosum as of rheumatic nature, it differed considerably clinically from the other forms of erythema so frequently seen in rheumatism.—Dr. MACLAGAN said that erythema nodosum was long ago regarded as a manifestation of the rheumatic diathesis. No doubt many things were called rheumatism, and errors were liable to creep in from the difficulty of diagnosis in some cases. That erythema nodosum was related to rheumatism was shown by the family and personal history of a case he had lately seen, in which the child had erythema, followed by chorea and heart disease, when his brother also became the subject of chorea.—Dr. HINGSTON FOX had met with cases of acute rheumatism and scarlatina in different members of one family; he thought there was a connexion between scarlatina, acute rheumatism, and erythema nodosum. Hebra regarded erythema nodosum as an inflammation of the lymphatic vessels.—Dr. B. O'CONNOR had found that the rheumatic symptoms had been of a very mild character in some cases of erythema nodosum.—Dr. LAYCOCK regarded rheumatism as of nervous origin.—Dr. A. MONEY said he had read Dr. Barlow's paper communicated to the Liverpool meeting of the British Medical Association, and agreed with its statements. He had never seen undoubted heart disease in immediate relation with erythema nodosum.—Dr. S. MACKENZIE said his conclusions had not been influenced by any previous bias on the subject. Dr. Wilks' criticism was a just one, but still none of the collected cases showed the slightest evidence of other disease than rheumatism, and the cases had occurred in the practice of different physicians at large hospitals. The redness and tenderness sometimes preceded the occurrence of erythema nodosum, and, although the eruption did occur in the vicinity of joints, yet he had seen the eruption not in their immediate neighbourhood, so that he could not accept Dr. Crocker's suggestion of local causation. He agreed that the relative frequency of heart disease and acute rheumatism was as Dr. West had stated. He considered that he laboured under some disadvantage in having to read in abstract the evidence which he had brought forward, but he fully believed that further investigation would support the conclusions at which he had been forced to arrive by the statistics collected by independent workers.

Dr. SAMUEL WEST read notes of three cases of Pneumothorax. The first case was one of sero-purulent effusion, which was tapped twice, the patient being in perfect health three years after the attack. The second case died from suffocation due to discharge of the viscid contents of a large cavity into the bronchial tubes. In the third case death occurred from hæmorrhage due to an aneurysm. In the first case sudden dyspnœa occurred whilst in bed three months before the patient was seen. There was no cough previously, but cough and expectoration after the sudden attack of dyspnœa. The patient was at work the day before. Ten days before admission the dyspnœa grew gradually worse, and was attended with pain in the side. Pneumothorax of the right side with effusion was diagnosed. Forty-one ounces of sero-purulent fluid were withdrawn. The pressure was high. A second tapping fourteen days later yielded twenty-two ounces of fluid. Complete recovery followed. Three years have elapsed, and the patient is well and active. The second case was one of phthisis of nine months' duration. The pneumothorax of the right side took place whilst the patient was in hospital. Death occurred two days later from asphyxia due to obstruction of the bronchi by the contents of a large cavity, emptied probably by the compression of the lung. The third case began suddenly three weeks before admission; there had been cough for two months, or five weeks before the attack. The patient was admitted with dyspnœa and hæmoptysis. Pneumothorax of the right side with effusion was diagnosed. Paracentesis was performed, and twenty-eight ounces of sero-purulent fluid withdrawn. Three weeks later thirty-six ounces were obtained. A few days later still, a purulent discharge took place at the site of the puncture. Then a free incision was made. Hæmorrhage from the pleural cavity set in two days later, and hæmoptysis occurred a few days afterwards. Exhaustion led to death without further hæmoptysis. In the first case the cause was probably phthisis; the pressure in the pneumothorax was high. The composition of the gas was discussed, and also the nature of the effusion. The dilated state of the veins was commented upon, and also the prognosis in pneumothorax. As to the second case, Dr. West remarked that the chief cause of the dyspnœa, discharge of the contents of cavities into the bronchi, was not often described. On the third case it was observed that aneurysm of the pulmonary artery and pneumothorax were but rarely associated; the processes which led to each condition were, so to speak, of opposite nature. A criticism of the proposed treatment of profuse hæmoptysis by the artificial production of pneumothorax concluded the interesting paper.

Mr. W. J. WALSHAM read a case of Lithotrity at a single sitting in a boy ten years old. A boy aged ten was admitted into St. Bartholomew's Hospital, July, 1884, for stone in the bladder. Mr. Walsham performed lateral lithotomy in August, 1884. The boy made a good recovery, and was discharged without signs of stone. He was readmitted in February, 1885, with a return of his symptoms; and on the 26th of that month Mr. Walsham at one sitting crushed and removed a stone, the larger fragments of which weighed fifteen grains and consisted of oxalate of lime. The boy had no bad symptom, and left his bed within three days of the operation. Although in this boy both the cutting and the crushing operations were successful, a comparison of the results of the two was most striking. After the cutting operation, although he had no bad symptoms, he had to remain in bed for over three weeks, and for the first few days necessarily suffered some inconvenience from the passage of urine through the wound; whereas, after Bigelow's operation, although he was kept in bed for three days for the sake of precaution, he was practically convalescent on the morning after the operation. The chief objections that have been raised to lithotrity in children are, to quote the words

Digitized by Google

of an eminent Indian lithotritist, Surgeon-Major Fryer, "that the genito-urinary organs are undeveloped, the bladder small, the urethra narrow, and the mucous membrane of both extremely sensitive and liable to laceration." That the genito-urinary organs are undeveloped, and that the bladder and urethra are smaller than in adults, are of course facts, but Mr. Walsham questioned whether they are objections to lithotrity in children. The undeveloped condition of the genito-urinary organs, by which presumably is meant, as concerns lithotrity, the undeveloped condition of the prostate, Mr. Walsham regarded as a positive advantage, as one of the chief difficulties in lithotrity in adults is referable to an enlargement of this organ; nor does he regard a small bladder, of course within limits, as a very serious objection—many lithotomists, Sir Henry Thompson among the number, preferring to work with the bladder containing only two or three ounces of urine. There are but few bladders, even in young children, that will not contain at least this amount. Even granting that the bladder is smaller than could be desired, it is more likely to be in a healthy condition than in adults, and if a little more injury is done to the mucous membrane, the forces of repair are all in favour of the child. With regard to the narrowness of the urethra, he had not the least difficulty in passing a No. 12 evacuating catheter after the meatus had been incised, and Dr. Keegan had found that the urethræ of boys of between four and six years will admit the passage of a No. 7 or No. 8 evacuating catheter, and the urethræ of boys of between eight and ten a No. 9 to No. 12. Experiments made by himself on the urethræ of children confirmed this belief. Mr. Walsham, moreover, questioned the extreme sensitiveness and liability to laceration of the urethra in children, and Dr. Keegan went so far as to pronounce this dictum as one of the time-cherished delusions in surgery. Dr. Keegan had performed the operation forty-two times in India on boys under twelve; and the success which had attended his cases showed that, even if such laceration occurs, it does no serious harm. Twenty of his patients were under the age of six; one was only one year and nine months. The smallest stone weighed 5 grains, from a boy of eleven; the largest, 236 grains, from a boy of seven, was composed of oxalate of lime. Mr. Walsham, in the light of this experience of Dr. Keegan and others in India, questioned whether lithotrity at one sitting ought not, as a rule, to be the operation undertaken in boys, whatever their age, as it had now become the operation in adults.—Mr. T. BRYANT considered that lithotrity was available for small stones. But the urethra was a tender and delicate part, and for large stones he thought that more damage might be done than would ensue from a lithotomy incision.—Mr. J. HUTCHINSON thought the Society was much obliged to Mr. Walsham for his case, and for the record of Indian experience. The operation was one that must be submitted to experience before a positive conclusion as to its practicability and value were decided upon. Certain disadvantages unquestionably appertained to the lateral operation in children.—Mr. BRUCE CLARKE spoke of the size of the urethra in young children. He mentioned one case in which a stone having the diameter of a No. 16 English catheter was liberated from the urethra.—Mr. R. W. PARKER referred to the statement of Von Langenbeck that in the lateral cutting operation the ejaculatory ducts were liable to be injured, with evil consequences later in life.—Mr. WALSHAM, in reply to Mr. Parker, could say no more than that the observer named and Mr. T. Smith had asserted that damage might be done to those parts.

The following living specimens were shown:—Mr. Bellamy: Enormous Vascular Tumour of the Upper Limb in an Infant. Mr. Stephen Paget: Synovial Cyst of the Leg in connexion with Disease of the Knee. Dr. S. WEST: Pneumothorax, with rapid recovery.

MEDICAL SOCIETY OF LONDON.

Evisceration of Globe of Eye.—Dislocation of Patella.—Bony Union of Fractured Patella.—Myxœdema with Contractions.—Spinal Sclerosis and Osteo-arthritis.—Lateral Sclerosis with knee-clonus but without ankle-clonus.—Amputation of Leg for Sarcomata.—Hereditary Tremor.

A CLINICAL meeting of this Society was held on Monday last, Mr. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. R. BRUDENELL CARTER showed a boy aged ten, whose left globe had been eviscerate by Dr. P. H. Mules' operation, by which an artificial vitreous body might be employed.

Mr. J. H. MORGAN exhibited a girl with outward Dislocation of the Left Patella on flexion at the knee. Hueter ascribed the deformity to congenital laxity of the ligaments, especially on the inner side of the knee; others regarded it as due to a partial paralysis of the triceps extensor; with the latter view Mr. Morgan could not agree.

Mr. A. P. GOULD exhibited for Mr. Batterham of Wolverhampton a man aged thirty-seven, with Bony Union of a Transverse Fracture of the Patella. A plaster-of-Paris bandage was applied immediately after the accident. Six days later he got up, and on the tenth day left the hospital. At the end of ten weeks a leather support was applied, and the patient was able to walk long distances without fatigue.—Mr. B. JESSETT referred to a case of compound comminuted fracture which he treated by plaster-of-Paris bandages, with the result of complete bony union. A second case of simple transverse fracture was also successfully treated by the same method.—Mr. ALLINGHAM, jun., also testified to the value of the method of treatment.

Dr. W. M. ORD showed a typical case of Myxœdema in a woman aged thirty-seven, in whom the affection had lasted fourteen years. In addition, there was persistent contraction of the muscles in the limbs; generally speaking, the limbs were in a state of extreme flexion, which could be easily overcome, but prevented the deep reflexes from being obtained; it had varied considerably from time to time, and the winter cold always made it worse. Dr. Ord considered that the contractions were of functional nature. The highest motor centres were in a state of feebleness, and incoordination sometimes resulted therefrom. Mental aberrations taking various forms were also observed in myxœdema. In reply to Mr. R. B. Carter, Dr. Ord said that no contraction of the triceps was obtained on percussing the patella tendon.—Mr. S. MACKENZIE spoke of the character of the tonic spasm, which differed from tetany and from the ordinary hysterical contracture, in which extension is a prominent feature. Did sleep make any difference in the spasm?—Mr. BEEVOR remarked on the tremor of the hands, which was also observed in experimental mxyœdema.—Dr. HERON said that one patient of his was perfectly aware of the long interval between the apprehension and the execution of a desired act.—Dr. D. DREWITT spoke of hereditary myxœdema.—In reply, Dr. ORD said he was unable to say in what parts the delay occurred; probably it varied in different cases. The spasm relaxed during sleep.

Dr. ORD also exhibited a case, apparently of Disseminated Spinal Sclerosis. All the joints of both hands were deformed, being of the nature of osteo-arthritis. Considerable thickening of the joints with ankylosis existed; there was much muscular atrophy of the hands, and also a glossy skin. The tremors and rigidity of limbs had in great degree diminished. The association of several dystrophies with the spinal symptoms was very noteworthy. The osteo-arthritis and atrophy of muscle and skin had been present about three years. Probably the loss of power, tremors, rigidity, and trophic changes were all due to one and the same spinal affection.—Dr. BEEVOR asked whether it might not be a case of paralysis agitans.—Dr. ORD could not accept this view.

Dr. STEPHEN MACKENZIE showed a boy affected with Lateral Sclerosis of doubtful date; probably it gradually began two years ago. There was present an unusual condition of the deep reflexes. There was no ankle-clonus, but a most marked bilateral knee-clonus, the vibration lasting as long as the tension was maintained. In reply to Mr. Carter, he thought there was probably a localised lesion specially involving the nerve apparatus presiding over the quadriceps extensor. The phenomenon in this case had been detected by Mr. Rawes, house-physician at the London Hospital.

Mr. PURCELL showed drawings of a case of Round-celled Sarcoma of the Deep Muscles of the Calf. Amputation was performed by the method attributed to Hardie of Manchester. He also showed a case of subperiosteal ossifying sarcoma of the tibia and fibula of a boy; amputation was performed. Secondary growths appeared later on in the head and spine, lungs, liver, and brain.—Mr. CARTER related a case in which the same operation was performed for compound fracture of the leg.—Mr. JESSETT said that the retention of semilunar cartilages in the stump prevented the retraction of the thigh muscles.

Dr. S. WEST showed a case of Hereditary Tremors. The tremors existed in all the limbs, especially affecting the hands. It resembled paralysis agitans in that on performing

Digitized by Google

volitional acts the tremors almost disappeared. The patient, a man aged fifty, was one of a family of ten, all of whom were more or less affected. The mother and grandmother were also the subject of the disease. He had six children, some of whom were affected. The affection began very early in life.—Dr. S. MACKENZIE had seen two or three cases of the same kind. The articulation was affected sometimes, and always made worse by excitement. He had seen the disease in very early childhood.—Dr. A. MONEY said the hereditariness recalled the disease known as chronic hereditary chorea, which also ran in families, but differed in coming on during adult life, and in being associated frequently with mental defects.

OPHTHALMOLOGICAL SOCIETY.

Coloured Drawing by a Colour-blind Artist.—Persistent Pigmentation after Jaundice.—New Formation of Pigment on Anterior Surface of Iris.—Staphyloma of Choroid.—Relapsing Cyclitis.—Herpes Facialis, with Affection of Eye.—Hæmorrhagic Glaucoma treated by Trephining.—Wound of Eye immediately followed by Iritis Serosa of the other Eye.—Central Guttate Choroiditis.—Glaucoma treated by Convex Lenses.

AN ordinary meeting of this Society was held on the 8th inst., Mr. Hutchinson, F.R.S., President, in the chair.

The PRESIDENT referred to the loss the Society had sustained by the death of Mr. Streatfeild, who had acted as its treasurer since the foundation of the Society. He paid a high tribute to Mr. Streatfeild's moral qualities, as well as to his surgical attainments.—Mr. BRUDENELL CARTER moved that a letter of condolence be addressed by the President, in the name of the Society, to Mrs. Streatfeild.—The motion was seconded by Mr. COWELL, and unanimously carried.

Mr. EDGAR BROWNE showed a drawing made from a copy by a colour-blind man. He had omitted the red, and substituted a rusty red for the green. The patient was unaware of his defect.

Dr. SEYMOUR TAYLOR showed a patient who had jaundice eighteen or nineteen years ago; the lower lids on both sides were pigmented, but on the left side the pigmentation had disappeared; the lower lid was of a dark green colour, and in the subconjunctival tissue of the lid there was a dark band of pigmentation, which did not affect the tarsal area.—The PRESIDENT had never seen a case where the same slaty colour of the pigment was present and had the same distribution. The case was quite distinct from chromidrosis.

Mr. NETTLESHIP showed drawings and microscopical sections of the Iris of four cases, where a new formation of pigment occurred on its anterior surface. In each eye there was a patch of pigment on the front of the iris; the new pigment had the same appearance as the natural uvea, with which it was continuous in one case. In this case microscopical preparations were made, and the new pigment was everywhere covered by a thin but distinct colourless layer, varying in thickness, and often showing scattered round nuclei or corpuscles; this lamina was continuous with the altered anterior basement membrane of the non-pigmented part; where the pigment was present the proper tissue of the iris was atrophied.—Mr. LAWFORD showed a similar condition in a less advanced stage; the eye had undergone iridectomy for glaucoma; there had been iritis.—Dr. BRAILEY thought Mr. Lawford's case fully explained by ectropion of the pigment layer of the posterior part of the iris, so common in advanced cases of glaucoma. The pigment was rolled far more into view than it is commonly. He regarded Mr. Nettleship's cases as of quite a different character, as in them the eye appeared to be otherwise normal. The appearances of the lithographic plate published by the same author in vol. v. were not consistent with the view of ectropion from glaucoma, and that was probably like the cases he showed to-day, and consequently entirely different from that of Mr. Lawford.—Mr. H. E. JULER had some sections in his possession which led him to take the same view.—Mr. LANG said that where the pigment appeared as a circular band around the pupil, the iris muscle was also turned upon itself, but that where the distribution of the pigment was irregular there was no eversion of the sphincter.—Mr. NETTLESHIP said that in one case, of which he had specimens, there was no doubling up of the sphincter, but the iris was atrophied at its free margin.

Mr. LANG exhibited a patient with Glaucoma and Coloboma of the Choroid, with Loss of Vision. The coloboma extended upwards and outwards, was narrow and long, and reached nearly up to the yellow spot. He did not know whether it was congenital or due to myopic staphyloma. As to traumatism, there was a scar in the cornea of the other eye, which was also somewhat myopic; but this was hardly sufficient to explain it. The patient had lived in Ceylon, and another patient from this region also had a scar on the cornea.

Mr. J. HUTCHINSON showed a woman suffering from Relapsing Cyclitis. At first sight syphilis suggested itself. There was iritis with ciliary congestion; also a dusky papular eruption on the skin, with sores on the lips. But the eye had been affected one year, and the other eye two years ago had undergone the same changes, with the result that the ciliary region was now thin and dusky. The cutaneous eruption had lasted two years; was better in summer and worse in winter. Mr. Hutchinson had also seen another case of the kind. Both patients had resided in Australia. The eruption had some resemblance to small-pox, and it left scars. There were indolent masses and tubercles on the fingers and ears, some of which looked like chilblains. The weakness of circulation which accompanied chilblains was possibly also operative in the production of relapsing cyclitis. Inherited gout and rheumatism perhaps played a part, as well as that condition of circulation that gives a proclivity to chilblains. In the case shown there was a strong history of a tendency to rheumatism, but none of gout; the patient had a cachectic strumous aspect.

Mr. WALTER H. JESSOP read a paper based on four cases of Herpes Facialis affecting the eye. In the first case the herpes followed the track of the external division of the supra-orbital nerve; the eye was affected with iritis, keratitis punctata, and increased tension; recovery, with perfect vision, occurred quickly. In the second, herpes along the lacrymal division of the ophthalmic nerve was followed by keratitis punctata and interstitialis. In the third case there was herpes along the frontal and lacrymal divisions of the ophthalmic nerve, early anæsthesia of the cornea, and superficial keratitis. In the fourth case the herpes followed the course of the infra-orbital nerve, and there were phlyctenular ulcers on the cornea. It was pointed out that herpes facialis followed the distribution of the fifth nerve, and that, when the eye was involved, the branch affected was usually the ophthalmic, but sometimes the superior maxillary. The most usual distribution was along the frontal, but there was no recorded instance of the nasal being the only branch affected, nor of the nasal and lacrymal branches being simultaneously attacked, while the frontal escaped. The fourth case was, he believed, the only recorded instance of the cornea being affected in herpes infra-orbitalis. Mr. Hutchinson had pointed out that the eye was affected if the oculo-nasal branch was attacked. The most common ocular complications were swelling of the lids, conjunctivitis, and increased lacrymation; the cornea might become affected by superficial ulceration, phlyctenulæ, interstitial keratitis, or keratitis punctata, and neuro-paralytic keratitis has been recorded. Serous or plastic iritis might occur, and the pupil, though generally contracted, has been found sometimes dilated. The chief affection of the fundus was papillitis. The tension was said to be generally lowered. Palsy of the extrinsic muscles and paresis of accommodation had been recorded. After referring to the post-mortem evidence of neuritis and dilatation of the ophthalmic artery, Mr. Jessop expressed the opinion that all the ocular symptoms, with the exception of the rarest, might be explained by supposing a dilatation of the vessels due to irritation of the sensory nerve. Vascular dilatation lasting some time would especially influence such a structure as the eye. If the whole attack were due to the neurotic storm, the different nerves would be affected nearly simultaneously, and the ocular symptoms would be coincident with the cutaneous eruption, which was not the case. Mr. Jessop attributed to Mr. Hutchinson the credit of first separating herpes accompanying the ophthalmic division of the fifth nerve from erysipelas.—The PRESIDENT said that it was a mistake to suppose that herpes zoster did not occur in apparently healthy persons. His observation, to which reference had been made, was that the severity of the disease was in proportion to that with which the tip of the nose was affected; and if the disease occurred in the latter situation, the eye suffered. It was desirable to bear in mind that the true definition of zoster was a neuritis, often

Digitized by Google

attended by skin disease; there were many cases where neuritis occurred and caused pain, but no skin lesion.

Mr. SPENCER WATSON showed drawings from a case of Hæmorrhagic Glaucoma in a man aged sixty-four; the sclerotic was trephined, and the choroid was accidentally perforated. The tension became normal, and so remained for three months, but without any improvement in vision. The tension, however, again rose, so that the result was most unsatisfactory.—Dr. W. A. BRAILEY said that in those cases where pain was severe and vision hopelessly lost the best treatment was to stretch the supra-trochlear nerve.—Mr. MCHARDY thought the case showed conclusively that the operation of trephining was liable to fail entirely to relieve the distressing tension in these cases. He had been astonished by the ease with which the supra-trochlear nerve could be found in the living subject.—Mr. EDGAR BROWNE had stretched the supra-trochlear in two cases without noticing any diminution in tension.—Mr. WATSON said, in reply, that since the operation pain had not recurred.

Mr. EDGAR BROWNE read a case of Wound of one Eye, followed almost immediately by Iritis Serosa of the other. The accident happened to the patient on Nov. 6th, 1885, after which he took a long railway journey, and in the severe cold. It was found on Nov. 7th that a wound of the left eye existed; the cornea was hazy, the pupil sluggish, and a thorn in the anterior chamber was found lying obliquely, fixed between the iris and posterior layer of the cornea; the anterior surface of the lens was opaque; the thorn was coated with lymph. Mr. Browne did an iridectomy on Nov. 7th. The next day violent pain was experienced in the other eye, which showed iritis with much congestion, but no dots on the cornea. A day later, however, keratitis punctata had developed. The wounded eye healed well, and by Dec. 23rd the mischief had altogether subsided. There was at no time any papillitis. It was discussed whether the case could be regarded as one of sympathetic serous iritis; there were difficulties doubtless in the way of accepting this view, but the facts alone were worth recording.

A paper on Central Guttate Choroiditis, by Mr. L. WERNER, of Dublin, was read by the SECRETARY. Its object was to point out that the "infiltration vitreuse de la rétine et de la papille," described by Dr. Masselon, was, in reality, the same disease as central guttate choroiditis. A drawing of the latter condition, published by Mr. Nettleship in the Transactions, vol. iv., showed a condition exactly resembling Dr. Masselon's drawings; the descriptions were practically identical, both authors describing the same small scattered dots of choroidal disease, apparently caused by deposit, equally distributed in both eyes, with retention of vision.—The PRESIDENT did not consider that the preservation of vision was a constant part of these cases, though the diminution of vision was not proportional to the amount of lesion.—Mr. ADAMS FROST quoted a case where vision was unaltered.—Mr. JULER referred to a case, previously recorded, where there was some disturbance of pigment, which supported the view that the affection was seated in the choroid.—Mr. NETTLESHIP had recorded the cases referred to by Dr. Werner for the reason that vision was not affected, though the patches were so numerous; as a rule, vision was affected. It was possible that the seat of these so-called colloid nodules might determine whether vision was altered. Where they occurred in the optic nerve, as was occasionally the case, vision was more liable to be affected, even though the number of nodules was small. He, of course, laid no claim to novelty in his paper, and the honour of first describing the condition belonged to Messrs. Hutchinson and Waren Tay.[1]—Mr. WAREN TAY said this disease was not necessarily central. Now and then a case was observed in which similar spots were purely peripheral, without the vision being affected. The patients need not be senile, for precisely similar spots were seen in quite young people. In the first cases noted vision was affected, but most observers had since seen cases where vision was unaffected.—The PRESIDENT had had an opportunity of comparing the condition noted in a drawing five years ago with the condition of the eye at the present time; there had been no alteration, and vision had slightly improved. Mr. Waren Tay had been the first person to call his attention to this condition, and the paper in the Ophthalmic Hospital Reports was founded on these first cases.

Mr. GEORGE E. WALKER gave an account of two cases of Glaucoma treated successfully with Convex Lenses. Case 1: A man aged thirty-three, in whom the left eye had been excised after two iridectomies for glaucoma. The right eye subsequently showed similar symptoms, and Mr. Walker ordered him to wear continuously spectacles with a 36-inch focus, which just neutralised his hypermetropia. When last seen, at the end of three months, vision was normal and the eye free from pain. Case 2: A man aged fifty-five, who since childhood had been liable to headache on attempting to read. In 1877 he began to have attacks of great pain in the eyes and head, with blindness. In 1883 he was told he had chronic glaucoma; iridectomy was done in the left eye, which speedily became blind. On October 28th, 1885, Mr. Walker found vision imperfect, the field narrowed, and tension increased. Vision was improved by a 20-inch convex lens; after using this glass for a fortnight pain had ceased, vision had improved, and the field had increased. He remained well up to the day of the meeting (162 days). On the previous day Mr. Walker had introduced homatropine in order to examine the fundus. He travelled to London, and on the following morning was found to be suffering from acute glaucoma. With rest in bed and fomentation, he improved so rapidly that, two hours before the meeting, he was in a fair way of recovery. The patient said that the attack resembled previous ones; and, though inopportune, it afforded an opportunity of proving that the previous attacks were of the same nature, though more severe. Mr. Walker maintained that these two cases, together with the previous one, which had remained well since, shown to the Society in 1884, afforded conclusive proof of the truth of his theory of the production of glaucoma, and afforded corroborative evidence that the ciliary body was not merely an engine of accommodation, but also a pump, or lymph-heart, for the purpose of forcing waste fluid from the anterior chamber into the vein.

Mr. W. H. JESSOP showed a new Pupillometer constructed on the same principle as a wire gauge.

Mr. BRUDENELL CARTER exhibited two Perimeters, the first of which was his original quadrant perimeter recently modified by Mr. Hawksley. The quadrant is formed of tubing, rectangular in section, and contains a small pulley concealed within its free extremity. The traveller which carries the object is attached to a length of fine catgut, also contained within the tube, which passes round the pulley, and also round a reel at the other or fixed end of the quadrant. The second perimeter was in essentials that invented by Dr. Dyer, of Newport, Rhode Island, and lately described and figured in the Transactions of the American Ophthalmological Society.

[1] Ophthalmic Hospital Reports, 1875.

OBSTETRICAL SOCIETY OF LONDON.

Contraction, Inhibition, and Expansion of the Uterus.—Mitral Stenosis in Labour.

A MEETING of this Society was held on Wednesday, April 7th, Dr. Black, Vice-President, in the chair.

Dr. MATTHEWS DUNCAN read a paper on Contraction, Inhibition, and Expansion of the Uterus. The uterus proper, or its body, is chiefly considered, but not to the entire exclusion of the cervix uteri and vagina. Contraction is temporary, and followed by relaxation and return to original dimension. It may be morbid in force, in duration, in rhythm, in extent. Contractions in childhood are believed to be present, and in the whole of menstrual life, and especially in menstruation. They are morbid in dysmenorrhœa spasmodica and may be tetanic. The rate may be six in an hour. Contractions perhaps occur in a fibroid, certainly around it, and especially at menstrual periods. The healthy contractions of pregnancy, to which Dr. Braxton Hicks has devoted much attention, are considered; they may be morbid and painful. Then come the contractions of abortion, miscarriage, and labour at term and in the puerperal state. When do pains commence? Then the commencement of labour is discussed; it is not the commencement of contractions, but of inhibition and of retraction. The internal os uteri is not the weakest part, but the fundus—at least according to mechanical principles. Stretching of fibres does not explain commencement of labour. The uterus grows to a size, and it is expanded by growth and a very slight force. The analogy of urination and of defecation with labour is considered. The necessity of inhibition of the circular fibres of the lower segment of the uterus is discussed. Morbid changes of inhibition are pointed out.

Digitized by Google

Lastly, the power of arresting and inducing contractions is mentioned.—Dr. HERMAN had had under his care in the London Hospital a case somewhat analogous to the examples of painful uterine contractions during pregnancy which Dr. Duncan had related. It was that of a patient with fibroids of the uterus, who suffered from severe paroxysmal uterine pains throughout the inter-menstrual period, these pains being only absent during menstruation. She was treated with ergot, which aggravated the pains. The cervix uteri was then dilated, after which the pains ceased, and they were absent for two or three months. They then returned, and the cervical canal was again dilated and the pains again removed. After this he lost sight of the patient. — Dr. CHAMPNEYS said that the antagonism existing between the opposite poles in the uterus had been called "polarity" by Reil, and he thought it was a convenient and concise term. Although Dr. Duncan had expressly stated that he was not now discussing polarity, it had formed a considerable part of the discussion on his paper, and Dr. Champneys had made these few remarks on that ground. He thought that spontaneous yielding of the cervix could not be denied in face of the following facts. In labour with contracted pelvis the head is sometimes arrested above the brim, the membranes present in the shape of the finger of a glove; but in spite of these conditions the cervix is found by the hand (introduced, perhaps, for the sake of turning) hanging flabby and relaxed almost as if labour had already occurred. Again, it sometimes happens that the os tincæ refuses to dilate, and remains rigid; however strong the labour pains may be under these circumstances, great retraction may take place, and Bandl's ring may be felt high up, the lower uterine segment being greatly thinned; the polarity is disordered, the expansion which should possess the lower pole of the uterus is replaced by contraction, and the result is a deadlock. In such a case, in presence of accidental hæmorrhage, he had turned by bipolar method, brought down a foot, and (apparently from reduction in the contents of the uterus) the cervix relaxed. He thought it could not be maintained that the external os was stronger than the internal. He would ask Dr. Duncan whether he had been able to distinguish the contractions of the vagina from those of muscles near it. Painful labour pains during pregnancy were like those of other hollow viscera in which disorderly contractions produced colic.—Dr. BRAXTON HICKS, without discussing the whole paper, wished to point out a fact not alluded to—viz., that during the last six weeks of normal pregnancy the os and cervix were in a large number of cases patent enough for one or two fingers to be readily passed in. When proceeding to induce labour at seven and a half or eight months he was often able to employ at once the largest size of Barnes' bags. The subject of the paper could not be fully discussed without this fact being taken into accoun.t — Dr. HORROCKS said that physiologists have formulated a law that whenever a muscle contracts its opponent relaxes. This law is applicable to all muscle, voluntary or involuntary. He illustrated the law by reference to various groups of muscles. The sphincter of the orifice of a cavity is the opponent of the walls of the cavity. Hence the cervix uteri relaxes when the fundus contracts. This is a physiological process known as inhibition, and doubtless has some nerve centre in the spinal cord or sympathetic plexuses presiding over it. If the longitudinal fibres in the cervix assist in opening the cervical canal, they are no doubt acting when their opponents, the circular fibres, are relaxing. Have we any means of affecting this inhibition and contraction by drugs or electricity? In his hands electricity has failed to bring on labour. Chloroform, chloral, and opium may to some extent inhibit uterine muscular action, but not electricity. The rhythm of the contractions is an interesting study. Dr. Boxall distinguishes two varieties of rigidity, muscular and fibrous. One or both are frequently operative, and they are often combined. The treatment must vary in the two cases. In omitting to relegate the rigidity to its cause may possibly be found the varying results obtained by electricity.—Dr. W. S. A. GRIFFITH, referring to the effect of electricity on the uterus, remarked on the great differences of opinion held by different observers, most of whom, however, appeared to agree with Dr. Horrocks that it was of little value in causing or increasing uterine contractions. Dr. Kilner, in a paper read two years ago, pointed out the value of the interrupted current in diminishing the acuteness of labour pains.—Drs. Galabin, Graily Hewitt, G. Roper, and Cleveland also spoke.—Dr. MATTHEWS DUNCAN, in reply, said that he was much fortified in his own views by the general concurrence of the gentlemen who had spoken. Some supposed differences of opinion were the result merely of different meanings of terms.

Dr. GEORGE COATES read a case of Mitral Stenosis in Labour. The patient was twenty-two, and had suffered from rheumatic fever, but had no suspicion of heart disease. She had suffered from anæmia and breathlessness. The labour began on Oct. 23rd, 1885. On the 24th she felt faint several times. On examining the heart a presystolic murmur at the apex was detected. In the evening the os was fully dilated, and she showed signs of exhaustion; the forceps were applied and delivery accomplished. The pulse varied in the next two hours from 180 to 130, then it fell to 108, and in the morning to 76. The murmur disappeared on and after the tenth day. On Nov. 13th she had a rigor, and sharp pain in the left breast, one elbow, &c. She was treated for acute rheumatism and recovered, the murmur quite disappearing.—Dr. HERMAN thought Dr. Coates' case interesting and instructive. He would be largely guided in the management of heart disease during pregnancy by Dr. Angus Macdonald's writings, but he thought that author took too unfavourable a view of the prognosis. Published cases and consultation cases contained too large a proportion of bad ones. Dr. Coates' case showed that pregnancy and labour might be gone safely through.—Dr. CHAMPNEYS said that Dr. Coates' case differed from most recorded and from those he had seen. All carefully recorded cases were valuable. Dr. Macdonald's work was from a very small number of observations. Mitral stenosis was supposed to be the worst form of mischief in these circumstances.—Mr. E. S. TAIT gave details of a similar case to that of Dr. Coates, but there was no acute rheumatic attack during convalescence.

The following specimens were shown:—Dr. W. S. A. Griffith: Naegelé Pelvis. Dr. John Phillips: Infant one month old with Fusion of the Phalanges of the Right Index and Middle Fingers (living specimen). Dr. John Phillips, for Dr. Playfair: Hæmato-salpinx with Ovarian Cyst. Dr. Benington; Meningocele in a New-born Child.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

A QUARTERLY meeting of this Association was held on April 8th in the Great Central Hotel, Carlisle, Dr. Campbell (Garlands, Carlisle) presiding. There was a large representative attendance from Scotland and the north of England. Papers dealing with important points in lunacy and the treatment of insanity were read by the Chairman, Dr. Keay, Dr. Campbell Clarke, Dr. Ireland, Dr. Wallis, and Dr. Greenlees, and considerable discussion followed. On the motion of the Chairman, seconded by Dr. Macleod of Beverley, the following resolution was passed:—"For the safety of insane patients, as well as those brought into contact with them, it is desirable that previous to removal to the asylum it should be the duty of the relieving officer effecting the removal to ascertain satisfactorily that such patients are not in possession of articles likely to cause injury to themselves or others." It was further agreed that copies of this resolution be forwarded to the Parliamentary Committee of the Association, as well as to the President of the Local Government Board and the Commissioners in Lunacy.

THAMES VALLEY DRAINAGE.—The Heston and Isleworth Local Board has received the sanction of the Central Board to borrow £77,000 for the purpose of constructing a separate system of sewage disposal for these two parishes. By the scheme to be employed the sewage, instead of being pumped up, will be forced through iron pipes to the proper level by means of Shone's pneumatic ejectors. After clarification by precipitation and filtration through land, the effluent will be discharged into the Crane, a tributary of the Thames.

AT a meeting of the governors of the Cardiff Infirmary on the 12th inst., it was resolved to let the old infirmary building to the council of the South Wales University College on lease for seven years at £400 a year rent, the College to spend £1000 in alterations of the building.

Reviews and Notices of Books.

Practical Surgery; including Surgical Dressings, Bandaging, Fractures, Dislocations, Ligature of Arteries, Amputations, and Excisions of Bones and Joints. By J. EWING MEARS, M.D., Lecturer on Practical Surgery and Demonstrator of Surgery in Jefferson Medical College, Surgeon to St. Mary's Hospital, &c. With 490 Illustrations. Second Edition. Philadelphia: P. Blakiston, Son, and Co. 1885.

Surgical Handicraft. A Manual of Surgical Manipulations, Minor Surgery, and other Matters connected with the Work of House-Surgeons and Surgical Dressers. With 233 Illustrations on Wood. By WALTER PYE, F.R.C.S., Surgeon to St. Mary's Hospital and to the Victoria Hospital for Sick Children, &c. Second Edition. London: Henry Kimpton. 1885.

To some extent these works cover the same ground. In each we have descriptions of surgical dressings, bandaging, and of fractures and dislocations. But Dr. Mears describes the ligature of arteries, amputations, and excisions, which are not included in Mr. Pye's book. In his turn, however, Mr. Pye deals with many matters not alluded to by Dr. Mears, such as the varieties and application of trusses, the use of catheters and bougies, the preparation of patients for operation, and many of the minor operations in surgery. The descriptions of surgical dressings are alike good in both books. Dr. Mears has gone to head-quarters for his details of antiseptic dressings, and we observe that the figures illustrating them are taken from Mr. Watson Cheyne's work. By the way, Mr. Pye speaks of immersing the instruments prepared for an operation in a solution of carbolic acid of the strength of 1 in 60 to 1 in 120, whereas the usual strength of the solution is 5 per cent., and it is certainly desirable to have it of this strength where aseptic surgery is aimed at. The application of bandages is plainly dealt with by each author, but Mr. Pye is much fuller than Dr. Mears. The latter's illustration of how the reverse spiral should be made is very inaccurate, and similarly the drawing of the breast bandage is at fault. Dr. Mears devotes 360 pages to the treatment of fractures and dislocations, and we are therefore surprised not to find any mention of Carr's splint for the treatment of Colles' fracture. The details of the application of the various means for arresting hæmorrhage are very imperfectly given by Dr. Mears; forcipressure is only mentioned, not described, and torsion is most imperfectly represented and inadequately described. Mr. Pye's account of the arrest of hæmorrhage is much better, but he fails to notice the importance of leaving on forcipressure forceps until an internal clot has formed, and of removing them with extreme gentleness so as as not to open up the vessel or displace the clot; when used in this cautious manner forcipressure is quite sufficient to arrest hæmorrhage from arteries the size of the lingual, if not larger. As regards torsion, Mr. Pye speaks with some reserve, and states that a healthy condition of the artery is essential to its success, and that in the case of large vessels the artery requires to be drawn out of its sheath and fixed by one pair of forceps while it is twisted by a second pair. Neither of these limitations is correct; markedly atheromatous or calcified arteries may be safely twisted, and the use of a second pair of forceps is quite unnecessary. Mr. Pye has reduced the size of his volume considerably, and has made some alterations in the text by excision and addition; he has thus added to its value and also put it within the reach of a much wider circle of readers. We are sorry to see that he has not included the old-fashioned carrot-poultice among his list of poultices; it is a very valuable application to bed-sores &c., and very few nurses know how to make it.

Text-book of General Botany. By Dr. W. J. BEHRENS. Translation from the Second German Edition. Revised by PATRICK GEDDES, F.R.S.E. 8vo, pp. 374. Edinburgh: Young J. Pentland. 1885.

WE are indebted to Germany for so many of the works on botany used in this country that the fact of being excelled in that science by another nation seems to have lost its sting; and we now receive from the hands of a well-known botanist at the university which has the largest botanical class in Great Britain a text-book of botany translated from the German, which might surely have been produced, one would think, by an English author, consisting as it does of well-known facts arranged in relation to the latest discoveries. The first glance through the book causes a feeling of wonder that Dr. Behrens' work should have met with the hearty reception it has done from teachers of botany, but this vanishes on a closer inspection of its contents. It is arranged in five parts. Part I., relating to morphology, is somewhat condensed, and presents no features worthy of special remark except the illustrations, which in this part, as throughout the book, are almost without exception excellent. Part II. is devoted to systematic botany. The classification and the names adopted for the groups are at variance with those in common use in this country, and here an editorial chapter is much required to explain the differences between the various systems of classification adopted on the Continent as compared with that followed in works on systematic botany in this country. On reaching Part III. the favour with which the book has been received is explained. Nearly one hundred pages are devoted to the fertilisation of flowers by insects and the natural modes of transport of seeds and fruits, a subject of great interest to students, and calculated to arouse their enthusiasm and to prepare them for the more abstruse parts of the subject which must subsequently engage attention in Part IV., which is devoted to anatomy and physiology, and in Part V., containing an account of the cryptogams. The illustrations in Part IV. will be found very useful, and the subject-matter adapted to give clear ideas to the student. In fact, Parts III. and IV. are the most valuable portions of the work. Part V. is too succinct, and the author in attempting brevity has in some cases sacrificed strict accuracy, and leads the reader into the danger of forming erroneous ideas; thus, Florideæ are said to be "distinguished by the circumstance that their spores are generated in capsules," a statement that, to say the least of it, is misleading. As a text-book, it certainly affords the teacher an opportunity of entering into details and explaining statements that without his help might seem contradictory, and to the student it affords an opportunity of obtaining a comprehensive but general view of the progress that has been made in the science during the last twenty years. The book would have been much more valuable had the reader been referred in foot-notes to works where a more extended knowledge might be obtained. Thus a reference under Algæ to Bornet's "Études Phycologiques," would have enabled the student to reach, in the subject of the Florideæ, the position in which the author proposes to place him—namely, "at the newest standpoint of science." But this omission is the fault of the author, not of the translator or of the reviser, whose work in each case is well done.

The Medical Register for 1886. London: Printed for the General Medical Council, and sold for the Council by Spottiswoode and Co.

The Dentists' Register. Printed for the General Medical Council, and sold for the Council by Spottiswoode and Co.

MEDICAL practitioners and dentists will be pleased at the appearance of these Registers. "Better late than never." We believe the delay is not the fault of the Council, nor of its indefatigable registrar. But there certainly is delay which

Digitized by Google

seems inexcusable, the Register for the year not appearing till after three months of the year have gone. We fear the Queen's printers, however well they print, print exceedingly slowly. The Medical Register is a work of importance, containing, in addition to the names and qualifications of all registered practitioners, much valuable statistical information. In one table (E., p. 68) is given the relative number of registrations effected in the three divisions of the kingdom since registration began; and in another (F., p. 69) the number of persons whose names have been entered in, or removed, for causes specified, from, the Register in each year from 1875 to the present. This volume contains about forty pages more than that for 1885. The difference is made up chiefly in the greater number of registered persons. The Register for 1886 contains the names of 672 more practitioners than that for 1885. We trust that the Medical Council will see its way clear to still further analyse and classify the facts contained in this Register. The number of each kind of qualification, the number of qualifications possessed by different registered persons, &c., are facts that would be more instructive and interesting than the number and date of each meeting of the General Medical Council. The Dentists' Register does not call for special notice. It shows that there are 5198 dentists in the United Kingdom, 82 per cent. of whom have no other qualification than that they were in practice before the Dentists Act.

THE BROWN INSTITUTION IN 1885.

MR. VICTOR HORSLEY'S report to the Committee of the Brown Institution for the year 1885 shows that a large amount of work of great variety has been prosperously and successfully carried on. A larger number of animals has been treated in the hospital than in any previous year, and at the same time the scientific research in the laboratory has been unremittingly pursued. Mr. Horsley finds that, owing to the great increase of work, it will be necessary to obtain a considerable sum of money in order to equip the laboratory with certain necessary instruments and apparatus which have hitherto been wanting. During the past year 3357 new cases of disease amongst animals were brought to the hospital of the institution for treatment. Of these we note there were 11 of glanders and farcy, 17 of rabies, 155 of distemper, 309 of parasitic disease. The most interesting part of the report is that concerning the laboratory. Twelve gentlemen, besides the Professor himself, have been engaged in original scientific work; this fact speaks volumes in favour of the establishment of a pathological laboratory situate in a more central part of London and having more accommodation. The Brown Laboratory is not a large place, and those who have been there best know its lack of accommodation. This makes it only the more surprising that so much good work could have been carried out under such incommodious circumstances. Dr. Berdez has made an investigation of the ptomaine produced by Koch's "comma bacillus." He has shown that the ptomaine produced by the active growth of Koch's bacillus is not apparently different from that produced in similar fluid, either by the growth therein of a common putrefactive bacillus or of Finckler's comma bacillus. Dr. Theodore Cash has been engaged in the investigation of the manner of destruction of pathogenic micro-organisms by other micro-organisms non-pathogenic in character. Dr. Cash has also shown that animals can be protected from the fatal effects of inoculation with anthrax bacilli by first bringing them under the influence of mercury. It is hardly possible to exaggerate the importance of this observation. Dr. Klein has discovered that the virus of foot-and-mouth disease is a micrococcus, cultivations of which are able to produce the malady. Full details were published in THE LANCET of Jan. 9th, 1886. He has also studied the action of perchloride of mercury on micro-organisms. It has been found that much stronger solutions (ten and fifteen times) than those mentioned by Koch are required to arrest the growth of or to kill micro-organisms. Pathogenic organisms are less resistant to perchloride of mercury than non-pathogenic ones. Spores are of course more resisting than the bacilli themselves; while, for instance, bacillus anthracis of the blood succumbs on exposure for thirty minutes to watery solutions of perchloride of mercury of 1 to 10,000 or stronger, spores have survived, quite uninjured, exposure in solutions of 1 to 10,000 for four days, and even 1 to 1000 for an hour. Mr. Lingard has continued his investigations into the intimate etiology of gangrenous stomatitis or noma. The same disease appears to exist in monkeys and calves as well as in man. The essential characters of the micro-organisms in all cases were similar. They consist of a leptothrix-like growth, the individual threads of which are made up of small bacilli. They occur in great numbers at the line of extension of the necrotic patch. Cultivations have been made from three cases in the human being, one case in a monkey, and numerous cases in calves. Mr. R. W. Parker and the Professor have investigated the question whether perfect reunion of tendons can occur when the divided ends are separated as far as possible. This question has been answered in the affirmative; so that it appears that the rapid method of treatment of tense tendons in orthopædic surgery is decidedly the best. Dr. Wooldridge has been engaged in the study of the coagulation of the blood. Perhaps the most interesting result obtained has been the isolation of a substance from perfectly fresh animal tissues, the injection of a solution of which into the blood of an animal causes rapid death. It causes death by producing intra-vascular fibrinous coagulation. In addition to causing intra-vascular coagulations, the substance curiously enough prevents the coagulation of shed blood. Of Mr. Horsley's valuable researches on the thyroid gland, on canine chorea, and on the relation that obtains between the posterior columns of the spinal cord and the excited motor portion of the cerebral cortex, we have already given full abstracts in THE LANCET of Jan. 9th and 16th, 1886.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary meeting of the Comitia was held on Monday, the 12th inst., at 5 P.M. Sir William Jenner, Bart., K.C.B., occupied the chair.

On the motion of the President, the thanks of the College were unanimously given to Her Most Gracious Majesty the Queen for her presence and assistance at the laying of the foundation-stone of the new Examination Hall for the two Colleges; and a vote of thanks was also passed to the Building Committee in general, and especially to the Registrar, Treasurer, and Assistant Registrar, for the trouble they had taken in making the arrangements for the ceremony so complete and satisfactory.

The draft agreement drawn up by the solicitors to the two Colleges for the joint responsibility and management of the new building was considered and approved. Permission was granted to the President to affix the College seal to the lease of the house in Knightrider-street. It was stated that the rental under the new lease had been increased from £30 to £250. The report of the Council on the question of conferring degrees in Medicine and Surgery, and an outline scheme for an examination in Arts in furtherance thereof, were received and referred to the Joint Committee of Delegates for consideration and report, without any expression of opinion by the College on the merits of the scheme.

An animated discussion on the report of the Croonian Trust Committee, in which many of the leading Fellows of the College took part, led to a postponement of the question until another meeting. The chief objections expressed were that the present Croonian Lectureship would be greatly modified by the new scheme, and that future lectures would be mainly devoted to therapeutic science instead of taking a wider range as at present, whilst there was also a great feeling against the surplus, after the lecturer had been paid, being devoted to payments for original researches or inquiries. The report of the committee, and an alternative scheme drawn up by Dr. Bristowe, were ordered to be printed and circulated among the Fellows.

The Medical Bills Committee and the Lunacy Bill Committee were reappointed to watch and report to the College on the Medical Reform Bill and the Lunacy Bills now engaging the attention of Parliament. Dr. West's proposals for the formation of standing committees were allowed to stand over until another meeting, and this concluded the business before the Comitia.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1886.

THE Fellows of the College of Physicians, and indeed the friends of London medical education generally, will feel a sense of relief in the statement we were enabled to repeat last week that Sir W. JENNER, if re-elected, would consent to hold the office of President for another year. If the occasion were an ordinary one, and the selection to the office were little more than a formal kind of recognition of the esteem in which a physician is held by his colleagues, the profession at large would not need to concern itself as to whether the changes in the presidency were quinquennial, or even annual. But the College of Physicians stands in a different position to-day. It is no longer a mere society of physicians; it has at last taken a very prominent part in promoting education, and its relations to the profession as a whole have become so much more intimate that the interest and anxiety felt as to the nomination of its President have greatly widened. Henceforth the College, in order to maintain its position, will have to look beyond its own interests, and will require to exercise its functions in a liberal and progressive spirit, very different from the manner in which it used to act. It has in a sense broken with the traditions of the past, and must see to it that no obstacle comes in the way of completing the work it has undertaken. Doubtless there are some within the College who regret this. They deplore the changes which are coming over the College, and the loss of its dignity and prerogative which they imagine must inevitably accompany such changes. No doubt they equally lament the disappearance of the Latin prelections and orations in which the Fellows were wont to exhibit their superior culture over the rank and file, and see in all this a degradation of a profession which from their point of view is hardly to be regarded any longer as "learned." An amusing example of the persistence of this superstition is to be found in the examinations for the Membership of the College, where the "culture" of a candidate is supposed to be tested by the translation into English of a passage from "Celsus" or "Aristotle." Happily the major portion of those in whose hands the fortunes of the College are committed see more clearly the position which the demands of modern medical education require them to take, and are determined that an institution which upheld the honour of medicine in the past shall not be content to rest upon its former glories, but shall lead the way in promoting everything that tends to the improvement of medical learning.

No one can doubt that there are many eminent men who would do honour to the College if chosen for the office of President; many whose labours, professional and educational, entitle them to the distinction which can be awarded to so few. Amongst the senior Fellows, whose Fellowships date from the years 1839 to 1859, we find, for instance, such names as the following:—Sir G. PAGET, Dr. REES, Sir H. PITMAN, Dr. C. WEST, Sir W. GULL, Dr. G. JOHNSON, Sir H. ACLAND, Dr. R. QUAIN, Dr. S. WILKS, Sir A. CLARK, and Dr. R. REYNOLDS. Without professing any knowledge of the views held by each of these gentlemen upon the questions which will for some time to come engage the whole attention of the College, it is plain that to some among them the office would be neither desirable nor possible. Thus neither Sir GEORGE PAGET nor Sir HENRY ACLAND could be expected to devote their time and attention to the affairs of the College of Physicians, holding as they do such important positions in the Universities and in the General Medical Council. Nor do we think that there is any precedent for provincial Fellows being elected to the presidential chair. It is not probable that Dr. OWEN REES, Dr. JOHNSON, or Dr. REYNOLDS would undertake the duties of the President's office, especially as the present circumstances demand so much from him in the prosecution of the affairs of the College. Dr. WEST has returned to the metropolis after a few years' sojourn abroad, and although he has evinced great zeal in pressing certain matters of reform upon the notice of the College, it may well be doubted whether he is sufficiently *au courant* with the medical curriculum of to-day to take the lead in the direction of educational reform. To Dr. QUAIN, we fear, objection must be taken, not on the score of his interest in educational matters, for he has been a moving spirit in the University of London and the General Medical Council, but because he has never warmly supported the conjunction of the College with the College of Surgeons. His famous Conjoint Scheme was found to be impracticable, but he may, for aught we know to the contrary, still cherish the hope of bringing it about, and if so the College would again be plunged into a state of discord. Moreover, Dr. QUAIN has never been connected with a medical school as a teacher, and that alone should be a bar to his preferment. Of Sir WILLIAM GULL's claims to this high office we would wish to speak with every respect. He occupies an eminent position in the public as well as in professional estimation. But he has not been reticent in regard to his opinions, and has declared himself so markedly in opposition to the attempt to secure medical degrees for students in London other than those furnished by the London University, that the Fellows may well pause before placing in his hands the power to direct the ways of the College. Of the three who remain, there can be no question as to the high qualifications of all, most especially of Sir HENRY PITMAN. There is no Fellow of the College who is more conversant with all the details of medical education than he, from the experience he has gained during his long tenure of office as Registrar. He perceives clearly the position which the College must assume in the future if it is to play the leading part in this matter. But Sir HENRY PITMAN is so useful in his present position that, although he has rightfully earned the gratitude of the College, it might be felt that by his promotion a vacancy would be caused which it would be most difficult to fill. Indeed we know that, if elected to the presidency, he would, in consequence of his advanced age, refuse the honour. Both Dr. WILKS and Sir A. CLARK have expressed themselves in favour of the College taking steps to secure to London students reasonable facilities for graduation. They are highly esteemed as physicians and as teachers, and if we might express a preference for Sir A. CLARK, it would be mainly on the ground that he has taken so active a share in the promotion of thorough medical training at the school

Digitized by Google

with which he is connected, and has, besides, evinced so keen an appreciation of the defects of the present curriculum, that he is likely to prove most zealous in the cause which a large body of English medical practitioners have at heart.

It is, however, fortunate that the Fellows will probably be relieved, for twelve months at least, from the necessity of weighing the claims of these and others to the office of President, as the Fellows will, we feel sure, be glad to express their sense of Sir WILLIAM JENNER'S services by re-electing him by an overwhelming majority.

IN pursuance of the resolution adopted by the College of Physicians in October—namely, "That it is desirable that persons examined by the Royal College of Physicians of London, and the Royal College of Surgeons of England conjointly, and found duly qualified, either by the ordinary or by an additional examination, should have a degree in Medicine and Surgery conferred upon them," the Council submitted to the Fellows of the College on Monday last an outline scheme defining the conditions under which the degrees should be conferred. Although this scheme was only formally introduced, and passed on for the consideration and report of the Committee of Delegates of the two Colleges, without any expression of opinion on its merits by the Fellows of the College of Physicians, its importance and interest necessitate some criticism of it on our part. We take it as an evidence, in the first place, that the Council of the College of Physicians has no intention to leave the question at rest now that the principle of instituting a degree in Medicine and Surgery has been confirmed by the authorities of the two Colleges, but to move another step forward. At the same time we feel that more is needed to put the degree on a satisfactory basis than is shown in this outline scheme.

The amendment moved by Dr. WILKS at the October meeting, to insert the words "or by an additional examination," indicated that the general feeling of the Fellows, as of the medical profession, was in favour of the present examinations being supplemented by some other before a degree could be conferred. The present examinations were to confer the Licence and Membership only, and then another examination would have to be passed before the conferring of the Degree. Many of the Fellows felt that this should be a supplementary examination in Medicine and Surgery, but the Council is evidently of opinion that the existing examinations in those subjects are sufficiently stringent even for candidates for a degree, and we are in agreement with it in this opinion. Since the formation of the Conjoint Examining Board the professional examinations have reached a high degree of excellence. It is in the preliminarary part of the medical student's education that the standard is so miserably deficient. The Second Class Certificate of the Second Division of the College of Preceptors is deemed sufficient for registration, and it is almost impossible to find a lower grade of examination in school subjects conducted by any responsible public body in the kingdom. It is obvious that, even if passing such an examination is permitted for the ordinary licences to practise, it is quite inadequate to test the general education of a future holder of a degree. Consequently the Council has recommended the institution of a special examination in Arts, to be conducted by examiners appointed by the two Colleges, and that this examination shall be compulsory on all persons who have not passed an equivalent examination in a University of the United Kingdom, India, the colonies, or in foreign countries, as recognised by the Board of Management of the two Colleges. It is not, however, laid down whether this Arts examination must precede the final examination, or whether it may be passed at any time before or after this; but we suppose that the latter view is the one favoured by those who drafted the scheme. The compulsory subjects are Latin, one other language, Arithmetic, Geometry, Algebra, and Elementary Mechanics, and two of the following optional subjects—namely, Greek, French, German, Italian, Spanish, Higher Mathematics, Experimental Physics, Elementary Botany, Elementary Zoology, English History, and Geography. It would be much more satisfactory if Experimental Physics, Botany, and Zoology were removed from this list, and, with the present examination in Chemistry, formed into a scientific group, the passing of which, as of an efficient Arts examination, could be made compulsory. No exception could then be taken to the thoroughness and stringency of the course laid down for obtaining the degree.

THE more the Medical Bill is examined the less do we care for it. We do not mean to say that it may not pass, or that, if the Parliamentary situation were different, it might not have a chance of doing so. The worse a Bill is, in some respects, the more is its chance of passing. A Bill that does some good, that removes a scandal, that reforms a corporation or a number of corporations, raises far more opponents than supporters. This is especially true of a Medical Bill. Dealing with a class of subjects and corporations about which the ordinary member of Parliament is in an absolute fog, the matter is abandoned to those in charge of the Bill; and those in charge of the Bill are apt to rely on this ignorance of the House, and to fear only the opposition which comes from bodies needing to be checked, reformed, or disestablished. These bodies can always find spokesmen in Parliament. A strong Minister, who would take the trouble, might in half an hour satisfy the House of Commons that the objects for which the profession has fought for fifteen years are reasonable objects—viz., a reduction in the number of licensing medical boards; a reduction in the members of the Medical Council, and its greater independence of the individual medical corporations; a fair representation of the profession in the Medical Council; and a penal clause more effective for punishing false and fraudulent practice by unqualified persons. Such a Minister would be able to show the House, too, that nearly all these objects had been supported by the Medical Council itself, and by a Royal Commission which had with great pains investigated the changes necessary in the examining bodies and in the Medical Council. We will venture to say that no public man could make this representation more effectively than Sir LYON PLAYFAIR, who knows more about the matter than probably any other man in either House of Parliament. And yet he has deliberately made himself the author of a Bill which secures none of these objects, which will pro-

Digitized by Google

bably tax the profession in perpetuity to keep up three times the number of corporations that are necessary, which dares not to disestablish the most glaringly superfluous bodies, or to attempt the most obvious reforms in the Medical Council. No one knows better than Sir LYON PLAYFAIR that the system of medical graduation has been most seriously disparaged of late, justly or unjustly, and that a proper Medical Bill should provide means for satisfying public and professional opinion as to its nature, as well as the sufficiency of the minimum examinations. But his Bill leaves the examinations of universities untested, save as to their being severe enough to imply mere professional competence in those who pass them. These are things that the Bill fails to do. What it positively accomplishes is to place the profession in an unprecedented degree under the rule of the Privy Council—to enable the Privy Council to compel the Medical Council to recognise foreign diplomas of which it disapproves; to enlarge the Medical Council by the addition of four direct representatives of the profession, who will find themselves confronted with twenty-four "old hands" in the Council, ready to uphold all its circuitous impotency for good, and all its ability for spending the scanty money of the profession without advantage. There are some medical reformers who are so enamoured of the idea of direct representation that they will support any Bill which grants this, in however delusive and ineffective a form. It will be curious to see if they will buy this concession at the great cost of the rule of the profession by the Privy Council. They will find that the author of this Bill has such a poor opinion of the Medical Council which is to be created by the Bill, that at every turn it is made to require the sanction of the Privy Council, or rather of two lords of that honourable body. We cannot ask for a more severe condemnation of the Council or of the Bill. The Bill of 1858 mentioned the Privy Council nine times. In this Bill it is quoted as a ruling authority between forty and fifty times. We are not prepared to purchase direct representation at such a cost. We do not suspect Sir LYON PLAYFAIR of any wish to harass or degrade the profession; but he cannot answer for his successors, who might be two eclectics or globulists, or patrons of bone-setters, who might override the Medical Council in the interest of their *protégés*, as it is to be dominated by the present Bill in the matter of unsatisfactory foreign diplomas. It would be far better to give the Lord President or the Vice-President a seat in the Medical Council, than to subject its chief actions to the will of the Privy Council.

PROFESSOR HUXLEY is among the prophets, and, like them, according to his idea of prophets and their work, he is "constantly striving to free the moral ideal from the stifling embrace of the current theology and its concomitant ritual." Why is this? As a scientist Professor HUXLEY is, of course, an agnostic. This is a necessity of his position *as a scientist*. Science does not know anything about the subject matter of religion. As a man, apart from his science, it is competent to Professor HUXLEY, as to every other intellectual being, to believe or disbelieve what he pleases. Are we, then, to understand that the Professor undertakes to expound the evolution of theology as a scientist or as an ordinary thinker? It is important to get at the truth about this, because if it is as a scientist the Professor writes, his propositions and reasoning must be tried by science; whereas, if he writes as an ordinary thinker, he is as much at liberty to indulge in speculations as is any other individual. It is only fair that Professor HUXLEY should tell us plainly in what light we are to regard him. As the matter now stands, we fear that, while on the one hand some simple-minded or careless reader may be misled by the impression that what the Professor has to say must needs be right and true because *he* says it, not a few who admire his strictly scientific work will be scandalised by the loose and illogical character of his speculations in theology.

The result of Professor HUXLEY'S two papers on the "Evolution of Theology" is *nil* in a scientific sense. This must be admitted by all, even including those who agree with him. He has not advanced the inquiry one step in any true sense. The most he has accomplished is to raise a doubt in the mind of the reader whether the Professor himself really knows what he means by evolution. Judged from a scientific standpoint, it would not be unfair to describe Professor HUXLEY'S lucubration on the "Evolution of Theology" as an awkward attempt to apply the principle of progressive development without any practical recognition of the cognate and inseparable principle of development by the environment. Because the Professor finds certain similarities of thought and aim in association in otherwise differing systems, he jumps to the conclusion that these several systems must needs have been evolved from that same original, wholly forgetful of the fact that similar surroundings must necessarily call out or evolve like, or more or less closely resembling, qualities from essentially different stocks. The outcome is mainly dependent on the compelling force of the environment. This is how species is developed. If the principle of development by the environment is to be subordinated to that of progressive evolution from an original, then the whole philosophy of the Darwinian method falls to the ground. Surely Professor HUXLEY must see this; and if he does, it follows that the discovery of certain similarities in the habits of thought, and the intellectual aims—so called—of diverse religions cannot be accepted, and ought not to be paraded, as evidence of a common origin. This fault—for as such we must regard it—of Professor HUXLEY'S method in the treatment of his subject places it wholly outside the boundaries of the scientific, and renders it difficult, if not impossible, for us to discuss it.

Meanwhile, how are we to explain Professor HUXLEY'S engrossment with this subject? When a man is satisfied in his own mind as to the truth or falsity of a theme or series of propositions, he is content to rest on his conviction, so far at least as his own intellectual consciousness is concerned. If Professor HUXLEY were a professional theologian, we could understand that it might seem to him necessary to keep himself and his views in evidence. Or if he were concerned to promulgate a new faith, we could see the reason why he should busy himself with the polemics of religion. But as at most he is only an image-breaker, and has nothing to set up in the place of what he destroys, we must confess ourselves at a loss to account for his activity. There have been such outbursts of mental energy as have

Digitized by Google

taken the form of almost passionate endeavours to re-establish crumbling convictions on firmer foundations. Is it in this light the "Evolution of Theology" is to be read? If so, we could wish that the frank spirit of truthfulness which has so greatly distinguished Professor HUXLEY'S career in science had also characterised his excursion into "theology," and that he had more candidly designated his latest lucubration by some title which would have told the story of his effort and presented it in its true character as an attempt to patch up a leaky craft in whose seaworthiness even its owner has begun to lose faith. We respect the honest doubts of any man, but when a doubter becomes dogmatic and strives to deepen his own disbelief by creating distrust in other minds, with no better materials and methods of reasoning than are set forth by Professor HUXLEY in his articles on the "Evolution of Theology," our respect is not enhanced, and we incontinently fall to wondering why a man of vast intellectual resources and altogether exceptional ability should thus disport himself.

PROFESSOR BOUCHARD, whose name is well known in connexion with original views on gout, rheumatism, and other diseases of nutrition, has lately investigated the interesting question of the poisonous character of normal healthy urine, and given the results of his researches to the Academy of Medicine of Paris. The question is at all times an interesting one, but perhaps more so at the present moment on account of the battles which are taking place in the Academy between the microbists and the anti-microbists, since any fact proving the poisonous character of the products of healthy metabolism will be hailed by the latter with delight.

The Professor commences by showing how substances which are indispensable to the healthy functions of the body may, when present in excess, merit the title of poisons, and no better example can be given than that of oxygen. It is undoubtedly indispensable, but when present in excess it kills by convulsions. In the same way, water, chloride of sodium, chloride of potassium, and other bodies, when present in excess of a certain proportion, produce death; so that the body of a man may be regarded as penetrated by various poisons introduced from outside or formed within, each of which has its particular route of elimination or is destroyed by intra-cellular oxidations, or is arrested and destroyed by the liver. Though we cannot determine the exact amount of poisons which may be in the body at a given time, we can determine the degree of toxicity of those which are eliminated by the various emunctories; we can determine what mass of living matter (always of course using the same kind of living matter) can be killed by the products eliminated by each organ of excretion; and we can form a unit of toxicity or "toxie," for the sake of comparison, by taking the amount which is necessary to kill a kilogramme of living matter. In this way we can determine what quantity of toxic units is eliminated in a given time by the kidneys, skin, intestines, and liver. M. BOUCHARD commences the study with the urine.

The poisonous nature of normal urine has been known since 1881, when it was studied by MM. FELTZ and RITTER, and again by Professor BOUCHARD in 1884. The first effect to be observed after an intravenous injection of from 10 to 15 cc. is a contraction of the pupil, which may become pin-point in size; the breath movements are much increased in number, but diminished in extent; movement is undecided and feeble; the secretion of urine is much increased, and the temperature is lowered, owing to a diminution of calorification; reflexes are abolished, and coma sets in, ending in death without convulsions, except slight muscular spasms. If now we try to determine the "toxie," or in this case the "urotoxie"—that is, how much urine is necessary to kill one kilogramme of living matter,—we meet with various numbers, depending partly on the state of dilution of the urine, but 45 cc. may be taken as the average. From this may be calculated the urotoxic coefficient of man—"that is to say, the quantity of 'urotoxies' which the unit of weight fabricates and eliminates in the unit of time. An adult healthy man eliminates in twenty-four hours, for each kilogramme of his weight, a quantity of urinary poison capable of killing 465 grms. of living matter. His urotoxic coefficient is then 0·465." From which it may be calculated that it takes a healthy man two days and four hours to manufacture sufficient poison to intoxicate himself. But, as was stated before, the toxicity of the urine varies from time to time and under different circumstances, and its properties were found to differ according to the state of waking or of sleep. During sleep less urine is excreted, but it is more concentrated, and accordingly it might be thought that the urine of sleep was the more toxic, but this was found not to be the case; the urine of sleep was less poisonous than that of waking. In eight hours of sleep a man eliminates from two to four times less urinary poison than during eight hours of waking. It must not, however, be concluded from this that sleep hinders the elimination of the poison. The period of minimum toxicity is just before sleep, and this then gradually increases till at the moment of waking it is five times as toxic, and eight hours after attains its maximum, which is nine times as great as the minimum, from which point it rapidly falls in eight hours to the minimum, to a new period of sleep. This difference in the characters of the urine may be partly explained by the fact that digestion takes place during the hours of waking, which might introduce into the urine an increased quantity of potassium or alkaloids associated with peptonisation, or the toxic matters of the bile; but that this can account for the totality of the difference is impossible, because the time of minimum toxicity would be at the moment of waking, instead of just before going to sleep. Moreover there is a qualitative difference as well as a quantitative; the urine of sleep has a convulsing, the urine of waking a narcotic, action; the one produces muscular spasm, the other sleep; so that, viewed in this light, the body produces during waking substances whose accumulation tends to produce sleep, and during sleep substances which act on the muscular substance, producing contraction and waking. And, further, the one kind of poisons is antagonistic to the other, so that if the urine is mixed in quantity proportionate to the amount eliminated, the product is not the mean between the two, but is considerably less. The toxicity is two-thirds of the sum of the separate toxicities.

IT will be recollected that the Royal Commission on the Housing of the Working Classes pointedly referred to the

Digitized by Google

failure in administration of sanitary laws in the metropolis, and remarked that "what at the present time is specially required is motive power, and probably there is no stronger motive power than public opinion." They recommended, therefore, that the Secretary of State should be empowered to appoint competent persons to inquire as to the immediate sanitary requirements of each district, having regard to the several powers entrusted to the local authority, whether the Metropolitan Board of Works or the vestry or district board; that the local authority should be empowered to nominate members of their own body to act with the officer so appointed, and that the reports of the results of such inquiries should be transmitted to the local authorities, and also should be laid before Parliament. Mr. GOSCHEN and Mr. LYULPH STANLEY were of opinion that this proposed survey of the whole of London, if made at all, should be undertaken on the responsibility of the new London Government, "to which the execution of the action which may have to follow such a survey will certainly have to be left." It was therefore evidently intended that this survey should be very thorough in its character, and should, we presume, be carried out on such lines as those followed by the officers of the Local Government Board.

It is with much regret that we find that the inquiries now being held by Mr. CUBITT NICHOLS very largely fail to carry into effect the apparent intention of the Commission. In our issue of the 3rd instant we expressed regret that the inquiry of Mr. NICHOLS into the sanitary condition of Clerkenwell was not more comprehensive, and although we thought it would give an impetus to sanitary work, we noted that many important points in the condition of the district had not received attention. This opinion is emphasised by a further report which has just been issued concerning the hamlet of Mile-end Old Town, and which deserves serious attention, for it contains in a more marked degree the shortcomings of the preceding report, and it may be accepted that the method of inquiry which is adopted in respect to both districts is that which will be applied to the rest of the metropolis. The inspector appears very much to have confined his observations to certain complaints which emanate from the Mansion House Council; this body is conferring a great boon upon London by its philanthropic efforts to stir local authorities into action, and is deserving of the warmest commendation, but we are unable to understand how this Council comes to be almost the sole means by which an inspector appointed by the Secretary of State receives his information. That it is so there can be no manner of doubt; for we find in the inspector's report the extraordinary statement that Mr. NICHOLS does not consider the hamlet to be in a bad sanitary condition, as the total number of houses reported by the Mansion House Council is but 508, or about 5 per cent. of the houses occupied either as lodging or tenement houses. There is not in the report a particle of evidence to show whether the Mansion House Council themselves profess to have made a complete survey of the whole hamlet; but even if they had undertaken this self-imposed duty, we fail to understand how a self-constituted authority has come to take the place of an investigator, who should not only possess all the technical knowledge which is required of a medical inspector of the Local Government Board, but have some authority from the State itself to make such inquiry.

We are forced to the conclusion that a course is being adopted which is very different from that intended by the Commission, upon whose recommendation these inquiries are being held, and that the Home Secretary has entirely failed to appreciate the meaning of a sanitary survey and its relations to the health requirements of a community. We are convinced that the error which is now being committed will be disastrous to the health interests of the metropolis, for the reports which are being issued as Parliamentary returns will carry with them all the weight which attaches to documents emanating from the Home Office, and will give an impression far different from that which would result from investigations conducted on other lines. We do not for a moment desire to imply that any other course than that adopted is open to any inspector, however able, if he lacks the medical knowledge of the kind required; but we are not the less sure that a sanitary survey of a district which is presumably intended to deal with the whole of the conditions affecting the health of its inhabitants, whether these conditions are subject to the control of a vestry, the Metropolitan Board of Works, or any of the other authorities having jurisdiction within the area, cannot be replaced by an inquiry whether the statements of a voluntary association are well founded. Such a survey requires primarily a considerable technical medical knowledge and detailed acquaintance with the health requirements of London. We sincerely hope, before further action is taken under the recommendations of the Royal Commission to which we have referred, that the Home Secretary's attention will be directed to the necessity of a complete alteration of the method of procedure, and to the advisability of introducing skilled medical experience into the investigation.

IT was with great pleasure that we were able last week to publish the result of the quarterly meeting of the Council of the Royal College of Surgeons, indicating as it appears to do the commencement of a more enlightened mode of treating the questions of reform now agitating the Fellows and Members at large. The chief of these questions, which have hitherto been received in a spirit of dogmatic opposition, have at last been discussed on their merits, and it is not surprising, as a result, that a very different view concerning them is now promulgated by the Council. Concerning the most important of these points—the representation of the Members of the College in or upon the Council,—the Council now recognise "the gravity of the question," as well as "the advantage of uniting in harmonious relationship all the constituent elements of the College." A more important admission could not be wished for, and we much thank the Council for it on behalf of the Members at large. Such a deliberate expression of opinion will give great encouragement to those who are working in the cause of this necessary and equitable reform, and cannot fail to aid in the settlement of the questions in dispute. Notwithstanding this admission, however, the Council still retain the opinion already expressed by them, "that

Digitized by Google

it is not desirable to diminish the privileges of the Fellowship by depriving Fellows of the exclusive rights of electing to the Council and of being eligible to become members thereof." While entertaining this view, it is only consistent on their part that they (the Council) should decline *to initiate* "proceedings for making any organic change in the constitution of the College which would impair the present status of the Fellows, by whom alone they have been elected to office." The Council, however, indicate not only the method to pursue in order to bring about the desired alterations, but assert also their willingness to give careful attention to any jointly authorised scheme of reform, approved by a majority of the Fellows and Members, which may be submitted to them. The initiation of a scheme of reform must therefore emanate from those who desire reform. The Council merely carry out the provisions of the Charter, and as a Council have no power to make alterations. We should be the last to find fault with the position which the Council now take up, as enunciated in their latest proceedings. Had a similar spirit prevailed two years ago, much unnecessary delay and ill-feeling might have been spared. *Mieux vaut tard que jamais.*

The "bipartite"—the academical and the political—character of the Fellowship is brought into special prominence by these last official utterances of the Council. Nominally founded "in order more effectually to promote and encourage the study and practice of the art and science of surgery," the Fellowship carries special privileges apart from the promotion of surgical science; and the Council seem more jealous of the political character than of the academical; they seem unwilling to lessen the political privileges, or to abate one jot or tittle of advantage which their exclusive possession seems, to their mind, to convey. On the other hand, as regards the *academical* status of the diploma the Council seem less mindful; they have from time to time lessened the severity of the purely academical tests, with a view to secure a larger number of applicants, while at a late meeting not only did they decide to elect a certain number to the Fellowship every year without any academical tests whatever, but they further proposed that Members of a certain standing should be admitted after passing a very modified examination. The question naturally occurs, Will the representation of Members of the College on the Council "impair the present status" of the Fellows? In other words, will privileges, at present enjoyed solely by the Fellows, be lessened in value, not by curtailing them, but by extending them to Members? We confess ourselves unable to see what the Fellows will lose, and therefore in what manner their present status will be impaired. On the other hand, we *do* think that any large increase in their number by methods other than the ordinary scholastic tests will lessen the academical distinction appertaining to this diploma. We would rather see justice rendered to the Members of the College by granting them corporate rights as such, than that the academical status of the Fellowship should in any way suffer, or the professional position of its holders be at all lowered, as it naturally will be by becoming year by year less select.

It now only remains to submit to the Council "a detailed plan," formulated by the two bodies mutually interested in the question—that is, presumably the Associations of Fellows and Members of the College,—embodying the changes which must be made in the present Charters by means of which political privileges shall be conferred on the Members. This is in accordance with the advice we offered in former articles. We would again impress this view on the two representative Associations. It is quite clear that for purposes of legislation the Associations will have to work together. The sooner this scheme of reform, which it is but right to mention has been formulated by the Association of Fellows, is drawn out and submitted to general criticism the better. It will probably have to be amended before it assumes a permanent form. The Council at length promise any such authorised scheme a fair field, and to discuss it themselves, as well as to submit it to a general meeting of the Fellows and Members.

On the whole, therefore, the prospect of reform at the College of Surgeons seems more hopeful than at any former time. It behoves those who have taken on themselves the laborious and irksome task of promoting and carrying out these reforms not to hesitate. We can only hope that the Fellows at large will appreciate the gravity of the question of the representation of Members, and the advantage of uniting in harmonious relationship all the constituent elements of the College. We would wish them to be liberal as regards what we have called the political aspect of the reform, and advise them to make a stand for the more purely academical exclusiveness of their order. As regards the Members, they must show themselves in earnest, and in sympathy with the proposed changes, by joining the Association in large numbers, and by communicating their views if unable to be present in person. We look forward to the realisation of this reform with no small anticipation, being convinced that it will prove advantageous, not only by raising the status of the individual practitioner, but by cementing into one solid body the somewhat antagonistic elements of which the College is at present composed.

Annotations.

"Ne quid nimis."

THE CROONIAN TRUST.

THE Royal College of Physicians is still in difficulties with regard to the disposal of its suddenly increased wealth under Dame Mary Sadlier's bequest. The scheme of the Council, which in May last was with several amendments thereto referred to a Croonian Trust Committee, has quite disappeared, and on Monday last a new scheme was submitted to the Comitia. Its chief provisions are the appointment of a Croonian lecturer, required to devote his lectures (not less than three and not more than six) to the discussion of "one or more subjects in anatomy, physiology, and pathology, in their bearing on therapeutic science, with a view to the more efficient prevention, control, and cure of disease." For these lectures he is to be paid half of the income of the Croonian Trust, which will in future amount to upwards of £200, and the remainder is to be devoted to "payment for such original researches or inquiries as may appear to the College to be most urgently called for." We fail to see how a bequest for promoting the study of anatomy can be legally transferred to therapeutical science, even if we

Digitized by Google

grant that there be such a science. Moreover, this scheme will, in effect, throw a large sum of money (£100) annually into the hands of juniors making researches in pathology and therapeutics, the bearing of which on the control and cure of disease may remain an unknown quantity for many years after the publication of their researches. Grants for original research and inquiry are given now by the British Medical Association, the Royal Society, and the Grocers' Company, and we doubt the advisability of the Royal College of Physicians devoting a moiety of the Trust to a similar purpose. The present Croonian lecturer is kept in no such narrow limits as this scheme proposes; he is always a physician of mature standing and clinical experience, and we greatly prefer the continuance of the existing system, or one on similar lines, to that suggested by the Committee. The ripe views and observations of a good clinical physician are well worth paying for, and are always at the command of the College. We are pleased to know that this scheme has fared no better than its predecessor, that Dr. Bristowe has proposed an alternative one more in accord with the views expressed above, and that the consideration of both of them, after they have been printed and circulated among the Fellows, has been deferred to a future occasion.

THE COCCI OF CROUPOUS AND HYPOSTATIC PNEUMONIA.

DR. LEHASHOFF publishes in the *Russian Weekly Clinical Gazette* an account of some observations made with a view to determine the frequency with which microbes are present in cases of croupous and hypostatic pneumonia. He examined sections, the liquid contained in the lungs, the contents of the smaller bronchi, and also the fluid of the cerebral ventricles, and in some cases the blood from the heart and large venous trunks. The ordinary methods of staining not being very satisfactory, the author undertook a series of observations for the purpose of improving upon them, and found that the best method of staining lung sections was to immerse them for from two to five minutes in an aniline solution of gentian violet, and afterwards for from four to fifteen minutes in an aniline or watery solution of eosin, then to wash them and dry them with alcohol, and finally to treat them with clove or cedar oil. By this method of staining the micro-organisms could be seen to be distributed in a very irregular way, usually in groups. The cocci found in the centre of a lobulus always preserved their ordinary form, and were strongly stained; while single cocci towards the circumference were often hardly to be distinguished, being but slightly stained. While some of the cocci presented a distinct envelope, others apparently of the same variety were seen close to them without any envelope at all. The size of the pneumococci was not constant, this being perhaps due to the manipulations the sections had undergone in preparing them for examination. The cocci seen by the author entirely corresponded with those described by Friedlander. Altogether there were examined forty-eight cases, forty-one of croupous and seven of hypostatic pneumonia. In the latter class of cases it did not seem that any characteristic cocci were constantly present, while in the forty-one cases of croupous pneumonia Friedlander's cocci were found in the lung tissue in thirty-eight cases. In eleven of these the fluid of the cerebral ventricles was also examined, cocci being found in eight. In the earlier stages of the disease the number of cocci was small; this gradually increased, attaining its maximum when red hepatisation was changing into grey. The blood was examined in twelve cases, but no pneumococci could be discovered. The observations were carried on by cultivations in jelly and inoculations of animals. For cultivations in jelly the liquid from the lungs, the blood and the fluid of the cerebral ventricles were used. Two kinds of colonies were met with. One kind was obtained after inoculation not only of pneumonia but of other diseases, and of putrescent blood. The second kind differed from these in being of a dull white without any admixture of grey, and in being distinctly raised above the surface of the jelly. This kind was only observed after inoculation from croupous pneumonia. From ten inoculations with pneumonic lung juice these colonies were obtained eight times; five inoculations with ventricular fluid were twice successful, and three inoculations with blood only once. Experiments with mice showed that when these animals were inoculated from colonies of the second kind they developed croupous pneumonia, and in one case out of three in which the greyish cocci were inoculated croupous pneumonia also followed, The author remarks that further observations are necessary on this subject, since mice are very subject to croupous pneumonia, and it is possible that numbers of other micro-organisms may have the power of setting up the disease in them.

DRAINAGE OF THE OXFORD VALLEY SCHEME.

IT is a matter of regret that the important scheme for the drainage of the Oxford Valley should have come to a stand-still. The original cause of the stoppage was the fear of the Oxford Water Company that the removal of the Iffley lock, one of the proposed alterations, would injure the water-supply. This difficulty, however, had hardly been overcome when a fresh objection was raised—viz., that the removal of the lock would drain the ditches and watercourses of the neighbourhood which now serve as boundaries. A fresh scheme was then proposed, by which it is intended to reconstruct the lock without altogether removing it. This plan, although beneficial for agricultural purposes, will not, it is thought, satisfy the sanitary requirements of Oxford, besides which it will be more costly. Now, as a considerable sum had been guaranteed both by the University and the city of Oxford for the original scheme of the commissioners, they naturally demur to subscribe to a new scheme, which will be more costly, and, as they believe, less effective. It is to be hoped, however, that some arrangement may be effected by which the original scheme may be carried out, since it is most important for the sanitary interests of Oxford that the flood water of the river should be rapidly carried off. We cannot help thinking that the damage likely to be caused by the removal of the Iffley lock has been greatly exaggerated; at all events, the experiment might be tried. If all the evil consequences predicted occurred, why then it would be easy to reconstruct the lock in the way now proposed; nor would this cause much additional expense, since in any case the lock would have practically to be almost entirely removed before it could be reconstructed. The fact that all the engineers consulted are in favour of the removal of the lock is a strong recommendation to give this plan a trial before proceeding directly with the work of reconstruction.

INCAPACITY OF JURYMEN TO SERVE.

AN adjourned inquest was recently held at the "George Inn," Bathampton, before Mr. Craddock, coroner, touching the death of Jessie Louisa Hill, aged forty-four. The deceased lady had suffered from nervous depression for some time, and, according to the finding of the jury, had ended her life by drowning during a fit of temporary insanity. The case is of interest to the medical profession in consequence of the course taken by the coroner in the matter of a certificate which had been given by Mr. Heygate, surgeon, to the effect that a juryman was unable to attend the inquiry in consequence of an attack of acute dyspepsia. The coroner, for some reason or other, seemed impressed with the idea

Digitized by Google

that the malady in question was not grave enough to excuse the absence of a juror. We are quite ready to admit that it would be well in all judicial inquiries, if, as usually obtains in the Superior Courts, the doctor certifying to the illness were required to state his opinion on oath. This was done on Monday last in the Central Criminal Court at the trial of the case Reg. *v.* Bartlett, where Dr. Broadbent went into the box to testify to the inability of Dr. Green to give evidence on account of illness. In this instance no question was asked as to the nature of Dr. Green's complaint, and rightly so, for it is not the province of the Court to inquire into the ailments of a witness or juror unless there are grounds for supposing that the doctor is not acting *bonâ fide* in the matter. It would have been better had Mr. Heygate been present at the inquest to support his certificate on oath; at the same time, we are at a loss to understand why the coroner should have considered *acute dyspepsia* an insufficient excuse for the non-attendance of the said juror. The term dyspepsia, like many others in common use, merely expresses a symptom or series of symptoms which may have for its cause some simple error in diet, an irritant poison, or an acute specific fever. But, from whatever cause arising, it certainly is not conducive to strict and close attention to the detailment of facts, and the formation of an impartial judgment upon the facts. Undoubtedly a considerable amount of inconvenience was caused by the absence of the juror, although, as we think, unavoidably; but a little tact would have served to ease off the friction which unfortunately took place. We advise medical men, whenever possible, to attend in person and give their opinion on oath.

EMBOLISM OF THE AORTA.

DR. VINCENZO CAMMARERI of Naples has published a memoir upon Obliteration of the Abdominal Aorta, which is summarised in *Le Progrès Médical* (No. 13). He has collected all the cases on record, starting from Barth's case in 1835 and Romberg's ten years later. In the majority the cause is embolism proceeding from the ventricle, the embolus being arrested at the bifurcation of the aorta, and leading to secondary thrombosis extending upwards—rarely above the level of the renal arteries, and downwards into the iliac arteries and their branches. The event is marked by the sudden appearance of complete and painful paraplegia. The sphincters are generally unaffected. Sometimes there is tetanic rigidity of the lower limbs; the reflexes and sensibility are abolished. Often in addition there are other symptoms—as hæmaturia, ischuria, suppression of urine, rachialgia, acute decubitus, &c. Whether a fatal result occur rapidly or not depends upon the extent to which the vessel is obliterated; in some cases, owing to partial obstruction or to a certain amount of collateral circulation, life has been prolonged for several weeks, or even months. The paraplegic symptoms have been ascribed by some to anæmia of the muscles, by others to anæmia of the cord; but the writer demurs to the latter explanation, except in cases where the coagulation has extended high enough to block the lumbar arteries; but even here he thinks the paralysis may be explained by interference with the muscular nutrition. Experimental ligature of the lumbar arteries in the dog produces paresis of the hind limbs, but the paraplegia equally follows the infliction of the wound without ligature. The author then explains the muscular paralysis following upon obstruction of the aorta as being due to the absence of oxygen and the presence of an excess of carbonic acid in the tissues. In like manner he explains the absence of reflexes; whilst the occurrence of muscular rigidity in some cases is compared with cadaveric rigidity—attributable, that is, to coagulation of myosin, and not to over-excitability of the muscle. The same "asphyxial" condition of the tissues is held to account for the anæsthesia, whilst the symptom of pain is attributed to irritation of nerve fibres from the presence of products of disintegration, the nerves being rendered excitable by imperfect anæmia or collateral hyperæmia. The lowered temperature, œdema, and gangrene are easily explicable by the stasis that is established, and the supervention of syncope from cardiac paralysis may be due to heightened arterial tension. The frequency with which aortic embolism is associated with mitral stenosis does not appear to be insisted on; but it is easy of explanation, since it is especially in such cases that thrombi sufficiently large to block the vessel are found in the auricle.

THE TOTTENHAM SANITARY ASSOCIATION.

THIS Association was formed twelve years ago in order to enable those amongst the inhabitants of the district who were interested in the subject to guide those concerned in some special matters connected with the administration of the laws relating to health; and although the work of health authorities has materially changed since its constitution, yet the Association still finds useful work to do. The report now issued is mainly a statistical one. It shows the present population of Tottenham to be 74,969, and it is striking to note that the number of unoccupied houses is 2338, or 15·5 per cent. of the total. But no less than 1659 new houses were erected in 1885. The death-rate for the year was 15·8 per 1000—that is to say, it is much the same as that prevailing in the twelve suburbs with which comparison is yearly made by the Association. Of the deaths from infectious fevers, there were no less than 63 from diphtheria, and the increasing fatality from this disease is very properly regarded by the Association as calling for the very earnest consideration of the sanitary authority and of the medical officer of health. The diphtheria deaths in the four years 1876-79 averaged some 5 per annum; in 1880 and 1881 they reached 10 and 20 respectively, and in the four years ending 1885 the numbers have been 27, 34, 48, and 63. When once diphtheria is recognised to be locally prevalent, deaths from that disease, which were formerly put down as due to other causes, are more correctly registered, but this alone cannot account for what must be regarded as a very serious feature in the recent sanitary history of Tottenham. Mr. R. D. R. Sweeting inspected Tottenham on behalf of the Local Government Board, during 1885, on account of this prevalence of diphtheria, and it is to be hoped that the recommendations which were appended to his report will be acted on. These recommendations aimed at removal of all obvious causes of disease, and it may fairly be anticipated that action in the sense they indicated will operate beneficially as regards diphtheria, as well as the general health of the district.

DRUNKENNESS AS AN EXCUSE FOR CRIME.

PERHAPS it would be more correct to say drunkenness as a negation of crime, for if there be crime there must needs be responsibility; whereas if there be no responsibility there cannot possibly be crime, the criminality lying in the progressive nature of the act, not in the act itself. This being understood, the question arises how far drunkenness absolves from responsibility. Dr. Savage of Bethlem discusses this topic in an interesting paper which appears in the *Journal of Mental Science* for April. There can be no question as to the responsibility of a person who knowingly places himself in a condition to do wrong unconsciously. The criminal act of getting drunk covers all that is done by the self-intoxicator; but questions arising in connexion with accidental drunkenness, or the permanent effects of drunkenness and hereditary demoralisation by drink, render the general issue extremely complicated. Practically

Digitized by Google

we think it should be understood and laid down as a principle that self-intoxication does not negative responsibility, and that the only question of extenuating conditions must take the form of an inquiry whether inheritance or disease rendered self-intoxication so abnormally facile as to justify the belief that the act of intoxication was unwittingly accomplished. The paper by Dr. Savage will repay perusal.

EFFECTS OF AN EXTENSIVE FRACTURE OF THE SKULL.

A CASE of extensive wound of the skull and brain is reported in the Russian *Herald of Forensic Medicine*. The patient was a man who had been struck by a piece of an anvil of about seven pounds' weight. The wound extended from half an inch above the concha of the left ear to the right parietal eminence. The fracture of the skull corresponded in length and position with the external wound. In many places it was splintered, the posterior edge of the fracture being raised above the level of the anterior edge. The whole wound was filled with crushed brain-substance, partly grey and partly white. There was both motor and sensory paralysis of the right arm. The power of sensation in the right leg was diminished; the pulse was 80 and the respirations 20; the temperature was also normal. The patient was fully conscious and in a peculiarly placid state of mind, being pleased with everything. He forgot, however, a number of abstract nouns and all proper names; his memory for numbers was also affected, and he had forgotten how to read. The wound was dressed with antiseptic bandages, and completely healed in fourteen weeks. During this time ten splinters were removed. The symptoms of amnesic aphasia gradually passed off. The memory for abstract nouns returned in about a fortnight. The placid humour passed away, and the man became decidedly irritable and suffered from insomnia and headache. The paralysis of the leg passed off during the first few weeks. Sensation returned in the arm and movement also, and after three months contraction occurred. After the lapse of eight months the man was still unable to read, and complained of constant headache and great feebleness of memory.

IS BOAT-RACING INJURIOUS?

THE annual contest between Oxford and Cambridge for aquatic supremacy proved this year to be one of unusual severity, and two, if not three, men in both crews towards the end of the race showed evident symptoms of distress. This fact has led to some sensational statements being made to the effect that some of the men will never get over the consequences of their exertions. We believe, however, that such statements have no real foundation, and, beyond the fact that the men were temporarily distressed, nothing like permanent mischief is likely to result. Some years ago, before the conditions of training were thoroughly understood, such rumours were frequent after each great boat-race, and even very eminent medical authorities set their faces steadfastly against boat-racing as an exercise. But a close inquiry into the after-history of the crews of the Oxford and Cambridge boats has proved conclusively that the mortality among the heroes of the annual race is certainly not greater than among the average of University men generally. The names of Sir Balliol Brett, Bishops Wordsworth, Selwyn, and Macdougall, Dean Merivale, Hon. G. Denman, J. M. Croker, and F. M. Arnold are well known as those of members of victorious crews more than forty years ago, who have survived up to quite a recent date—indeed, some are still living; and to these may be added names, less known to fame, who were still able to answer *Adsum* when the roll was called a few years since Sir George Burrows, who is still living, has told us he took part in one of the earliest of the College races on the Cam, quite fifty years ago; whilst Lord Penrhyn, who has just died at the advanced age of eighty-six, was a member of a crew who in 1824 performed the extraordinary feat of rowing, with five others, from Oxford to Westminster Bridge within sixteen hours, a distance of 118 miles, with many locks to pass through, in one of the heavy wherries and with oars of the period—a performance far more severe than rowing a four-mile race: for, with a heavy six-oared wherry, they had to keep up the pace continuously, except at the locks, for sixteen hours, at eight miles an hour; whilst, with light outriggers, sliding seats, and improved oars, the pace of the racing eight is little over twelve miles an hour for twenty minutes. A reason in favour of boat-racing as an exercise is the fact that the progress from ordinary to severe exertion is made very gradually. The tyro who first commences to row has to learn first to manage his oar; as soon as his muscles get accustomed to the weight, he is taught to bring his whole muscular system into action to propel the boat; but this has to be done gradually, otherwise he will acquire awkward habits. As soon as he has learned to row he begins to cultivate pace, but this has to be practised cautiously, since if allowed to "blow" himself he will soon row out of form; and it is only by degrees that the bursts are lengthened as the "wind" improves. Next, after considerable preparation, come the "trial" races, in which the men's physical and staying powers are closely watched; and then comes the final selection into the crack crew. The result is, that an unsound man is usually found out long before the severe trial comes; whilst, for sound constitutions, a course of systematic and careful training tends to improve the physical and vital powers, and fits men to undergo the strenuous exertions of a boat-race without injury.

DOCTORS' DOOR-KEEPERS.

WE must confess to a strong persuasion that, as a rule, it is better for a "doctor's door-keeper" to be a male than a female. An exception may be made in favour of women servants in attendance at the houses of certain specialists—for example, the gynæcologists; but, speaking generally, we think it is more decorous that the door should be opened by a man than by a woman, looking to the mixed character of the gathering in most waiting-rooms, and the service which has not unfrequently to be rendered to those who are infirm or weakly. As to the idea put forth by a contemporary that doctors' door-keepers are "got up" to look impressive—that, of course, is absurd. Opening the door to a considerable number of sickly-looking folk, for the most part accompanied by friends with anxious countenances, is not an inspiriting occupation, and it is scarcely to be expected that the doctor's door-keeper will wear a particularly jovial expression, but it should suffice that he is respectful, self-possessed, and well-behaved, and if these qualities can be secured both doctor and patient may well be satisfied.

"THE DOCTORING OF THE POOR."

UNDER this heading the *Echo* of April 5th contained an article which proposed the establishment of the local doctor as the parson is established, making him accessible to all. So far as the Poor-law service is concerned, this is already done to the extent which public and social prudence seems to render reasonable. The class a little above the pauper is fairly well provided for at the dispensaries and the out-patient rooms of hospitals. We must confess to thinking that a great deal of weak sentiment is expended on the subject of doctoring the poor. The "poor" are, on the whole, better cared for in respect to their medical necessities than the classes a little above them. The real difficulty of

Digitized by Google

the day is how to provide efficient aid in sickness for those who when they are in health support themselves by honest industry, but who when they are stricken down by disease are not only themselves helpless but place their belongings on the brink of pauperism, and this through no fault or wrong-doing of their own. These deserve our deepest sympathy, and their necessities call for a remedy which it is difficult to devise.

SIR HENRY PITMAN AND THE MEDICAL COUNCIL.

SIR HENRY PITMAN has resigned his office as Representative of the Royal College of Physicians of London in the General Medical Council. Sir Henry Acland is understood to be in the East, and there is no immediate prospect of a meeting of the Council. Sir Henry Pitman's object in resigning at present is to give the College ample time to choose his successor. It will not be easy for the College to find a representative so efficient. Sir Henry Pitman's knowledge of College affairs, his good judgment in professional and medico-educational questions, and his long experience, are qualities not easily acquired. To the Council his loss will be almost greater than to the College, for, in addition to the above qualities, he had a faculty for work and business which made him most valuable as chairman of the Business Committee of the Council, in which capacity he did his best to develop methodical and business-like habits in the Council.

INFANT FEEDING.

THE old difficulty of bringing up children by hand received a fresh illustration at an inquest on the death of an illegitimate child at the Totnes workhouse during the past week. From the report of the *Totnes Times* of the 3rd inst. we gather that the infant in question was taken from its mother when fourteen days old. It came under the care of Dr. Hains, the surgeon to the workhouse, who suspected it to be the subject of hereditary syphilis. Dr. Hains directed that the child should be fed exclusively on milk. When one month old it was somewhat fretful, and the matron on her own responsibility ordered baked flour to be added to the milk. It appears from the report that the doctor had explicitly forbidden to the nurse in charge the use of any solid food for the infant. When fourteen weeks old the child died rather suddenly, and on post-mortem examination solid pultaceous food was found in masses in the stomach, and to the irritation produced therefrom Dr. Hains attributed the cause of death. The matron, on examination, appears to have insisted on the use of baked flour as a routine article of food for young infants, and even maintained that the extra three ounces of bread allowed by the Local Government Board (obviously for the nursing mother) might be used for the food of an infant a day old! Such an observation is hardly worth notice except as an illustration of the views of female Bumbledom; but we gladly seize the opportunity of emphasising the principle that, with all deference to the matrons of workhouses, in the feeding of infants as well as in regard to their physic the doctor's directions should be implicitly obeyed. The mere "quieting" the child, though it counts for something, is not the "be all" and "end all" of bringing it up. But, to be perfectly fair, we must face the difficulty that diluted cow's milk is often an inadequate food for infants. Although in the case in question no doubt Dr. Hains was right as to the origin of the "pultaceous bullets" found in the stomach, yet we can testify to the occasional passage from the alimentary canal of extremely hard, compact masses of solid casein due to the incapacity of the infant digestion to deal effectively with cow's milk. How to treat this idiosyncrasy, which is not so very rare, is a great difficulty when we have to do with ignorant and obstinate nurses. The fretfulness of the child causes the nurse to rush at once to some form of starchy food, which may no doubt to some extent help mechanically by leading to the diminution of casein coagula, but is in itself indigestible. Some very simple and expeditious plan of partial separation and digestion of the casein of cow's milk is a desideratum. As a useful and nutritious diluent of cow's milk we have found the time-honoured barley-water the best of all, and attended with the minimum of disadvantages. But we cannot too often insist on the perils of hand-feeding, and that the way in which many illegitimate English children are often torn at a tender age from the nourishment of a mother's breast, are fed by rule of thumb, and die without organic disease but of practical starvation, is a continual scandal.

HEALING BY FIRST INTENTION AFTER OPERATION FOR FISTULA.

DR. RUIDNOVSKI, having found that after operations for anal fistula in rural districts where there was no hospital accommodation, and where the hygienic conditions were bad, it is often difficult to get the wounds to heal by second intention, determined to make an attempt to obtain union by first intention by means of sutures. A boy of fourteen with an anal fistula was operated upon in this manner; the sinus was found to be not single, but complicated with two lateral sinuses. After the incision had been made into the gut, the soft tissue between the sinuses and the granulations were all scraped away with a Bruns sharp spoon, the surfaces of the wound being brought together by a deep and a superficial row of sutures. Opium was given, and in a week's time the dressings were removed and the wound was found to have healed perfectly by first intention.

EDUCATION OF THE BLIND IN BOARD SCHOOLS.

THE late Mr. Fawcett believed that every occupation which is ordinarily possible for people with sight may and should become possible for the blind. The right hon. gentleman was able during a not very long life to show that his courageous creed was no mere theory, but that it could be carried out with marked practical success by one possessed of education though deprived of the sense of sight. Education, however, is the indispensable qualification to all profitable advancement. That special difficulties stand in the way even of its partial attainment by the blind cannot be denied, but it is also beyond question that such impediments have often been completely surmounted; and it is probable that care and method inspired by past example will greatly lessen their power of opposition in time to come. We are inclined to think that our Education Department might realise more fully than it does this capability of the blind for receiving instruction, as well as its own comparative fitness and capacity for imparting it. Societies, endowed schools, and hospitals are understood to be charged with the culture of this outlying field, and they have accomplished, without doubt, a great amount of really good work. Such efforts, however, must needs have but a limited influence. Is there no means of contriving that a part of the machinery of the Board of Education should be utilised to supplement the efforts of these older charitable establishments? The question has already suggested itself to one of the blind themselves, Mr. William J. Day, who in a pamphlet on the subject recommends that the training of blind persons should form part of the national system of elementary instruction, and should be compulsory. He denies that any considerable departure from present usage or any need of special qualification, is implied in the necessary employment of embossed as compared with ordinary printed letters. In the general tenour of these remarks

Digitized by Google

we concur. Some inconvenience, it must be allowed, may conceivably arise from the general introduction of this plan. We might, for example, find ourselves confronted with the anomalous spectacle of one or two blind pupils in a school, and under tuition by teachers more numerous than themselves. A comparatively large district might furnish but few blind inhabitants, while of these a still smaller class —the young—would be eligible for ordinary elementary instruction. The incongruities which must result if each of these attended different schools would, however, be obviated, at all events in towns, by selecting one school in every such district, and making provision in it for blind scholars. We are not without hope that some such plan may yet be found to be practicable, and while we are unwilling to wander far from the central theme of this discussion, we venture to make the suggestion that another defect, still more difficult to treat—that of deaf-mutism,—may also some day come to be included within the widening range of the School Board administration.

CHOLERA IN BRITTANY.

THE reported recurrence of cholera in Brittany enforces the caution contained in our recent issue as to the danger which this country may have to face during the rainy season on account of cholera on neighbouring coasts. For the moment no news is forthcoming as to the prevalence of the disease on the north coast of Spain, but there can be little doubt that cholera is prevalent in certain portions of Brittany, and especially in and about Treboul. Probably the disease is of a more or less sporadic character, and hence the denials as to the existence of Asiatic cholera; but whatever form the disease assumes, it is clear that it is an affection having very near affinities to the epidemic which prevailed in France in 1884 and 1885; and in view of the communications between the coast of Brittany and our own coasts by means of fishing-boats, &c., it is important that our port and riparian sanitary authorities should be on the alert.

JONATHAN HUTCHINSON, LL.D.

THE University of Glasgow has been singularly happy this year in its selection of those whom it pleaseth to honour. We announced last week that the University had conferred the degree of LL.D. on Professor Pettigrew, and we have now the great pleasure to add that the same honour has been offered to, and accepted by, Mr. Jonathan Hutchinson, who although not an *alumnus* of that University, or, we believe, of any university, is, of all medical scholars, one of the worthiest recipients of so truly eminent a distinction.

BOARDING-OUT OF PAUPER CHILDREN.

MR. STANSFELD, in answering a question on this subject on April 9th, expressed his strong approval of this system, and said that there were 141 unions in which guardians were empowered to board-out children under duly appointed committees. He also said that a lady had been appointed to visit the children, and that her report will soon be published. We have repeatedly expressed approval of this system. It requires, however, the supervision of persons interested in the children.

THE FATE OF THE LOCK HOSPITALS.

NOW that short-sighted agitators against the Contagious Diseases Acts have ridden their hobby to the death, what is to become of the nine Government Lock Hospitals, providing in all 626 beds? Are these most useful agencies in the cause of moral and physical health to be disestablished, or simply left to rot in idleness? From 1864—when the first of the Acts, now unhappily repealed, was passed—to 1870, the total number of beds available for the treatment of these special diseases was raised from 40 to 666, and mainly by the action of the Government. Unless something be done, and at once, it must be anticipated that a great and good work will be summarily arrested, to the lasting injury of the services and of the general population, and the further degradation of public morals.

SEWER AIR IN THE HOUSES OF PARLIAMENT.

THE Committee appointed to investigate the ventilation of the Houses of Parliament has hastened to report the all-important discovery that sewer air pollutes the contained atmosphere of the Houses. Great structural reforms will be indispensable for the final remedying of this grave fault; but, without waiting for this, the Committee recommend immediate measures to mitigate the evil. There ought not to be a moment's avoidable delay in adopting the course suggested. If the air of St. Stephen's be not simply unduly carbonised, but actually tainted with sewage exhalations, it is manifest that our legislators are exposed to grave perils, which cannot be permitted to exist after they have been pointed out.

INVERSION OF THE TEMPERATURE CURVE.

DR. CORIVEAUD draws attention in the *Journal de Médecine de Bordeaux* to some cases of pneumonia in children in which the ordinary temperature curve was inverted. A similar observation has, it seems, been made by Damaschino in a thesis published in 1867, as he says: "In broncho-pneumonia the evening exacerbation is not always constant. In some cases the fever is as high in the morning as in the evening; in others the morning readings are even higher than those taken in the evening." Hirtz, too, in his article "Chaleur," in Jaccoud's Dictionary, mentions that in acute phthisis the morning temperature is occasionally higher than the evening.

TYPHUS IN LONDON.

IN 1869, when the deaths from "fever" in the Registrar-General's reports were first returned under the three headings, typhus, enteric or typhoid, and simple or ill-defined, 716 deaths were referred to typhus in London. Since that date the deaths referred to this cause have remarkably and almost steadily declined, and it appears from the Annual Summary for 1885, just issued, that only 28 deaths were referred to this disease during last year in London, against numbers declining from 92 to 32 in the preceding four years, and against an average (corrected for increase of population) of 106 in the ten years 1875-84. Typhus, under the influence of more energetic sanitary administration, is undoubtedly becoming a rare disease in England, but part of the rapid decline of deaths from typhus in London in recent years is more apparent than real, for formerly a very considerable number of deaths were incorrectly referred to typhus, which was used (as, unfortunately, it was in the Registrar-General's reports until 1869) as a generic term for "fever." There is very good ground for doubting whether all the 28 deaths referred to this disease in London last year were really cases of typhus; 2 were of children under five years of age, 8 of young persons aged between five and twenty years, 4 of persons aged between twenty and forty, and 14 of persons aged between forty and sixty. It may be noted that 6 of the 28 fatal cases were recorded in the fever hospitals of the Metropolitan Asylums Board, corresponding with the number in 1884, when the total deaths referred to this disease were 32. It appears from the Registrar-General's annual summary that, after distributing the hospital cases, 8 of the 28 last year belonged to East London,

Digitized by Google

including 3 to Poplar and 2 to Whitechapel sanitary areas; 10 belonged to South London, including 5 to Camberwell and 2 to Greenwich; and 3 belonged to Islington and 2 to Hackney sanitary areas. It is noteworthy that only one fatal case of typhus belonged to Central London, where the density of population is greatest, and where the general death-rate shows so large an excess; this death from typhus belonged to the sanitary area of St. Luke's. With a view to finally stamping out the disease in London, the isolation of a larger proportion of the occurring cases is essential, and it is scarcely satisfactory to note that of the 556 deaths referred to this disease in the past eight years only 143, or 26 per cent., occurred in those hospitals. It may perhaps be assumed, however, that the remaining 413 included all those cases that were incorrectly referred to typhus.

THE ATMOSPHERE OF RAILWAY CARRIAGES.

A CONTEMPORARY expresses a preference for death by "asphyxia," to death by cold from sitting in a draught. We are not quite sure that, even granting the somewhat shaky use of a technical term, this preference is well grounded; but, however that may be, there is no sort of reason for making a selection. It is not necessary to choose between closed and open windows in travelling by rail. Nothing could possibly be easier than to ventilate a carriage moving rapidly, by a very simple and obvious contrivance of air-chambers in the roof. There need be no down draught, and certainly no difficulty exists in providing effectually for the egress of impure air and the introduction of pure air. The fact of movement overcomes the obstacle to ventilation which exists in the case of a fixed chamber.

SCURVY AFTER BAD HARVESTS.

FROM the report of the medical department of the province of Perm, in the eastern part of Russia, we learn that, owing to bad harvests in 1883 and 1884, the inhabitants suffered severely from scurvy in the succeeding years, the localities where the harvest had been the worst suffering the most. Statistics show that each year the disease began to manifest itself in the month of February, increasing in severity till May, when it attained its maximum, from which time it regularly decreased till September, when it was at its minimum.

COLONIAL EXHIBITION HOSPITAL FUND.

A SUGGESTION made by Dr. J. H. Aveling that donation boxes to collect a general fund for the London hospitals should be placed in the Colonial Exhibition, has, we learn, been approved by H.R.H. the Prince of Wales, and steps are being taken to obtain the fullest advantages from this important concession.

TOY BALLOONS.

IT seems that the little toy balloons or indiarubber bladders which children inflate with the breath may be readily reversed by inspiration and even drawn into the air passages. In two instances recently death has occurred by suffocation, a balloon of the sort being drawn into the opening of the glottis. This is a matter of danger which ought to be recognised. Parents and nurses should be on their guard.

FOREIGN MEDICAL APPOINTMENTS.

DR. C. DELYANNI has been appointed Professor of Clinical Medicine in the University of Athens. It is announced that a chair for Syphilis and Dermatology is to be established in Athens. Dr. J. Steiner has been appointed Extraordinary Professor of Physiology in the Medical Faculty of Heidelberg.

IN his report to the Registrar-General on the results of his analysis of the water distributed during the month of March by the several metropolitan water companies, Dr. Frankland states that, taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, he finds that the proportional amount contained in an equal volume of water supplied by each of the metropolitan water companies and by the Tottenham Local Board of Health was—Kent, 0·6; Colne Valley, 1·2; New River, 1·2; Tottenham, 1·6; West Middlesex, 2·4; Southwark, 2·5; Grand Junction, 2·6; Lambeth, 2·7; East London, 3·1; Chelsea, 3·4. The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained in every case less organic matter than was present in the February, and still less than in the January, samples. The water drawn from the Lea, and distributed by the New River and East London Companies, exhibited a similar reduction in the proportion of organic matter present. All the samples were clear and bright on delivery.

DEPUTY SURGEON-GENERAL SKEEN, whose death we announced last week as having occurred on the 2nd inst., was born in 1833, and, having received his professional education at King's College, obtained in 1855 the licence of the Royal College of Surgeons of Edinburgh, and in 1859 the degree of M.D. at King's College, Aberdeen. In 1855 he entered the army, and after considerable service on the Gold Coast he was elevated to the rank of staff surgeon, and in 1861 took part in the Gambia expedition against the Mandingoes. He afterwards served in the West Indies and in India. From 1876 to 1879 he was stationed at Aberdeen, and during the latter year was sent to South Africa; here he was engaged in the Boer war, acting as senior medical officer of the Transvaal, and being with the forces in Pretoria during the siege. For his services in South Africa he was frequently mentioned in the despatches. In 1880 he was made brigade surgeon, and was appointed Deputy Surgeon-General in 1884, when he returned to this country.

MR. T. FISHER UNWIN is about to publish a work entitled "Medical Missions: their Place and Power." It is written by the Rev. John Lowe, the secretary of the Edinburgh Medical Missionary Society, and will contain an introduction by Sir William Muir. It will also be further embellished with a medallion portrait of Dr. John Abercrombie, the founder of the above Society.

AT their last meeting, the Council of King's College promoted Dr. Urban Pritchard to the Professorship of Aural Surgery, in consideration of the great services he had rendered to the hospital as Aural Surgeon during the past ten years. We believe that this is the first professorship in aural surgery that has been instituted in this country.

DR. THEODORE WILLIAMS, having completed fifteen years' service as Physician to the Brompton Hospital for Consumption, has, on the recommendation of the medical committee, been unanimously re-elected by the Committee of Management for a further term of five years.

MR. OULESS has finished the portrait of Sir Henry Pitman, and it will be presented to the College by Sir Risdon Bennett, on behalf of the subscribers, at the meeting on the 19th inst., previously to the election of the President.

THE death is announced of Dr. Joseph Nowak, Professor of Hygiene in the University of Prague.

Digitized by Google

PROF. F. S. DENNIS, of New York, has recently had under his care a case of double gluteal aneurysm. The treatment he adopted was to perform a laparotomy, turn aside the viscera, and then ligature the two internal iliac arteries in the pelvis. The patient succumbed to chronic renal disease a week after the operation.

ON the 11th inst. the death occurred at Liverpool of Mr. Thomas Pennington. The deceased, who was born in 1807, obtained the licence of the Society of Apothecaries in 1828 and was admitted a member of the Royal College of Surgeons in 1829.

MR. CUBITT NICHOLS' report on the sanitary condition of Clerkenwell has just been presented to Parliament, and will shortly be published.

M. VULPIAN has been elected, after a sharp contest with M. Milne Edwards, as permanent secretary to the Physical Science section of the French Academy of Sciences.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Blackpool Urban District.—Dr. Welch issues a very complete report on the sanitary state of this borough, and it calls for the more attention because Blackpool constitutes one of the most important of the holiday resorts in the north-west of England. The infant mortality is excessive in Blackpool, and this is due in the main to such causes as diarrhœa, chest and wasting diseases, and so-called convulsions. As regards diarrhœa, Dr. Welch, who has mapped out the cases which occurred according to locality and to soil, is of opinion that it is mainly due to excessive moisture and high temperature acting conjointly on filthy surroundings, and he urges that it is in the direction of increased cleanliness, such as will aim at securing perfectly clean air, food, soil, and water, that improvement must be looked for. The suggestion as to the connexion of diarrhœa with filth is certainly borne out by the fact that enteric fever, which, though less frequent than it was, is still too frequent, coincided in point of distribution with diarrhœa, and of sixteen separate occurrences of enteric fever eleven were found to be associated with filthy conditions of premises or serious drainage defects. In some respects there is in Blackpool considerable scope for an active sanitary authority. The sewer ventilation has for some time past been a matter calling for attention, and Dr. Welch points that he is in entire concurrence with Dr. Page of the Local Government Board as to the need for improvement in this respect. He urges too, and with reason, that the fitting of charcoal trays to ventilating shafts is mainly instrumental in preventing the dilution of sewer air, and hence of ventilation, because the trays act as a barrier to the in-current of fresh air. He also presses for a proper hospital for infectious diseases, instead of the make-shift, which, by reason of site and accommodation available, fails to satisfy the most reasonable demands either of the public or of the medical profession. Blackpool has compulsory registration, and yet it has made no permanent arrangement for the isolation of two separate infectious fevers. But still the town can lay claim to a death-rate of only 15·3 per 1000, and this may be taken as an indication of what its possibilities are as a health-resort.

Coventry Urban District.—With a population of 46,739, Coventry may be congratulated on an annual death-rate for 1885 of only 16·2 per 1000. There were also only two deaths from any of the continued fevers during that period; and altogether the deaths from infectious fevers have been exceptionally low for at least two whole years. This result is doubtless, in the main, due to the persistent efforts which have for some time past been made in this ancient borough to get rid of causes of preventable disease, and to isolate the first attacks which come under notice. Dr. Mark Fenton's report gives evidence of maintained activity in these respects, and especially so in the closure of wells and in the extension of the public water-service to houses and to closets. Then, again, Coventry has long worked successfully with a temporary iron infectious hospital, and during 1885 as many as 101 patients were admitted, a corresponding number of centres of infection being thus removed from amidst the population. But the advantages secured by early isolation have been made so evident that a more attractive and suitable building was last year completed on a site of some five acres, where accommodation for twenty patients, each with 2184 cubic feet and 153 feet of floor space, has been provided. Dr. Fenton now urges his authority to go forward in other directions, and above all to deal with certain unwholesome areas and to provide a public abattoir, both of which are eminently necessary in order to secure permanency in the improved condition as regards mortality which has been attained, and with a view to wholesomeness not only of premises now bordering on existing slaughter-houses, but of one of the principal food-supplies of the population.

Sunderland Port District.—The increase in the inspection of vessels in this port is most satisfactory. In 1876 the number inspected was 965; last year it had reached 2142, and it involved inquiry as to the accommodation of no less than 23,490 persons, including crews and passengers. The effect of these inspections and of the operations resulting from them must be very widespread, and, indeed, Mr. Harris tells us that the sanitary condition of the ships is steadily improving; the average percentage of those which are good, or fairly so, being 84. Of 478 foreign vessels examined, 12·3 per cent. were in a distinctly insanitary state, but amongst British ships the rate reached 16·5 per cent. This is the reverse of creditable to a nation that professes to take the lead in such matters at sea as well as on shore; but from reports which we have received as to other ports we believe the Sunderland experience to be exceptional. German and French vessels compared unfavourably with British ones; the Dutch and the Danish ones were best kept. All reports as to port districts refer to the bad ventilation of forecastles; and it is to be hoped that the attention of shipbuilders may before long be pointedly drawn to this matter. A cowl with which Mr. Harris has experimented goes far to remedy the evil, and it has the advantage of getting rid of the foul air without risk of admitting water. Difficulties are experienced in Sunderland port in connexion with the isolation of infectious diseases. Perhaps in the action now being taken by the urban authority a solution of the question may ultimately be found.

Southend Urban District.—Excluding the deaths amongst visitors, the death-rate for 1885 was 15·2; including these it reached 17·7 per 1000. The little make-shift cottage hospital served to prevent a spread of small-pox. The dust question is a difficulty here, as elsewhere, where the authority try to get the scavenging done by contract instead of doing it themselves. Efficiency in filth removal is what should be aimed at, and not a mistaken economy, and this especially in a town which is professedly a health-resort. Mr. Phillips points out that improvements in connexion with the system of sewerage have been effected by the provision of tall ventilating shafts, and that the through-ventilation of new house drains is being enforced.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6120 births and 3500 deaths were registered during the week ending April 10th. The annual death-rate in these towns, which had been equal to 29·3, 26·4, and 22·2 per 1000 in the preceding three weeks, further declined last week to 20·1, and was lower than in any previous week of this year. During the thirteen weeks of last quarter the death-rate in these towns averaged 24·4 per 1000, and corresponded with the mean rate in the first quarter of the ten years 1876-85. The lowest rates in these towns last week were 15·5 in Hull, 15·9 in Bradford, 16·3 in Wolverhampton, and 16·6 in Sheffield. The rates in the other towns ranged upwards to 25·6 in Manchester, 26·8 in Blackburn, 27·8 in Preston, and 28·7 in Portsmouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 430, 406, and 359 in the preceding three weeks, were 364 last week; they included 131 from whooping-cough, 121 from measles, 37 from diarrhœa,

Digitized by Google

26 from "fever" (typhus, enteric, or simple), 21 from scarlet fever, 21 from diphtheria, and 2 from small-pox. No death from any of these zymotic diseases was recorded last week in Hull, Huddersfield, or Halifax; whereas they caused the highest death-rates in Blackburn, Preston, and Portsmouth. Whooping-cough caused the highest death-rates in Manchester and Derby; measles in Oldham, Birmingham, Plymouth, Blackburn, and Portsmouth; and "fever" in Preston. The 21 deaths from diphtheria in the twenty-eight towns included 15 in London. Small-pox caused 1 death in London and its outer ring, 1 in Bristol, and not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 7, 8, and 11 on the preceding three Saturdays, had further increased to 13 at the end of last week; 3 new cases were admitted to these hospitals during the week, against 5 and 4 in the previous two weeks. The Highgate Small-pox Hospital contained 3 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 917, 710, and 506 in the preceding three weeks, further declined last week to 350, and were so many as 160 below the corrected weekly average. The causes of 77, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes were duly certified in Birmingham, Leicester, and in three other smaller towns; and the largest proportions of uncertified deaths were registered in Cardiff, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 27·9, 24·7, and 21·6 per 1000 in the preceding three weeks, further declined to 21·2 in the week ending April 10th, but was 1·1 above the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 15·1 and 17·8 in Dundee and Edinburgh, to 23·4 in Paisley and 24·6 in Glasgow. The 524 deaths in the eight towns showed a further decline of 10 from the numbers returned in recent weeks, and included 12 which were referred to diarrhœa, 11 to whooping-cough, 6 to measles, 4 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 2 to scarlet fever, and 1 to small-pox; in all, only 39 deaths resulted from these principal zymotic diseases, against 62 and 46 in the preceding two weeks. These 39 deaths were equal to an annual rate of 1·6 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The 12 deaths from diarrhœa slightly exceeded the numbers in recent weeks, and were 4 above the number in the corresponding week of last year. The fatal cases of whooping-cough, which had been 29 and 14 in the previous two weeks, further declined last week to 11, and included 9 in Glasgow. The 4 deaths from measles exceeded the number in the previous week by 2; 4 occurred in Edinburgh. The 4 deaths referred to "fever" were below the average of recent weekly numbers, and 6 below the number in the corresponding week of last year; they included 2 in Glasgow. The fatal cases of scarlet fever and diphtheria were also below the average. The death classed as small-pox (contrary to the system of classification used by the Registrar-General of England) was one attributed to chicken-pox in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 204, 148, and 134 in the preceding three weeks, further declined last week to 109, and were 25 below the number returned in the corresponding week of last year. The causes of 90, or more than 17 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 40·5, 34·6, and 34·4 per 1000 in the preceding three weeks, further declined to 33·0 in the week ending April 10th. During the thirteen weeks of last quarter the death-rate in the city averaged no less than 33·5 per 1000; the mean rate during the same period did not exceed 24·8 in London and 20·0 in Edinburgh. The 223 deaths in Dublin last week showed a further decline of 10 from the number returned in recent weeks, and included 16 which were referred to the principal zymotic diseases, against 18 and 15 in the previous two weeks; 11 resulted from whooping-cough, 3 from "fever" (typhus, enteric, or simple), 2 from scarlet fever, and not one either from small-pox, measles, diphtheria, or diarrhœa. These 16 deaths were equal to an annual rate of 2·4 per 1000, the rates from the same diseases being 2·3 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 12 and 6 in the preceding two weeks, rose again last week to 11. The 3 deaths referred to "fever," on the other hand, showed a decline of 2 from the number in the previous week; and the fatal cases of scarlet fever were fewer by one. Eight inquest cases and 9 deaths from violence were registered; and 65, or considerably more than a quarter of the deaths, were recorded in public institutions. The deaths of infants and of elderly persons were fewer than those returned in recent weeks. The causes of 21, or 9·4 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Grenadier Guards: Surgeon Hugh Rayner, M.B. Medical Staff, to be Surgeon, vice G. B. Stuart, M.B., promoted.

ARMY MEDICAL STAFF.—Surgeon-Major Edward Joseph Boulton is granted retired pay, with the honorary rank of Brigade Surgeon. Surgeon Oswald Gillespie Wood, M.D., to be Surgeon-Major. The undermentioned Surgeons to be Surgeons-Major:—Lloyd Brereton Ward, William Birkmyre Miller, M.D., George Blake Hickson, John Prendergast, James Adolphus Smith, John Martin, John Joseph Greene, M.B., Nathaniel McCreery, Joseph Andrew Gormley, M.D., John Edward Vaughan Foss, M.D.

INDIA OFFICE.—The Queen has approved of the retirement from the service of the undermentioned officers of Her Majesty's Indian Military Forces:—Brigade Surgeon John Houston, M.D., of the Madras Army, and Surgeons-Major Richard Thomas Lyons, M.D., and James Kelly, of the Bengal Army. The undermentioned officer is granted a step of honorary rank on retirement:—Brigade Surgeon George Alder Watson, of the Bengal Army, to be Deputy Surgeon-General. The Queen has approved of the following promotion, amongst others, among the officers of the Staff Corps and Indian Military Forces made by the Governments in India:—Surgeon-Major Henry Potter, M.D., of the Bengal Medical Establishment, to be Brigade Surgeon.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Connolly, M.D., has been placed on the retired list of his rank.

The following appointments have been made:—Inspector-General of Hospitals Timotheus J. Haran, to Plymouth Hospital; Staff Surgeon George H. Madeley, to the *Phaeton*, and Staff Surgeon Robert Turner to the *Hotspur*.

MILITIA INFANTRY.—4th Battalion, the Royal Welsh Fusiliers: Surgeon John Richards is granted the honorary rank of Surgeon-Major.—3rd Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon J. Corbet is granted the honorary rank of Surgeon-Major.—Nottinghamshire (Southern Nottinghamshire): Surgeon I. Massey, M.D., is granted the honorary rank of Surgeon-Major.—3rd Battalion, the Royal Irish Regiment: Surgeon John Percy Waddy is granted the honorary rank of Surgeon-Major.—5th Battalion, the Rifle Brigade (the Prince Consort's Own): Surgeon George P. Bate, M.D., is granted the honorary rank of Surgeon-Major.

ARTILLERY VOLUNTEERS.—1st Aberdeenshire: Surgeon J. Rodger, M.D., is granted the honorary rank of Surgeon-Major.—4th Durham: Surgeon S. Gourley is granted the honorary rank of Surgeon-Major.—1st Inverness-shire: Finlay Matheson Mackenzie, Gent., to be Acting Surgeon.—1st London (the City of London):—The undermentioned Surgeons are granted the honorary rank of Surgeon-Major: F. G. Bennett and V. Ambler, M.D.—2nd Middlesex: Surgeon R. T. Daniell is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment): Surgeon O. C. Maurice is granted the honorary rank of Surgeon-Major.—3rd Durham (the Sunderland): Surgeon C. Nattrass, M.D.,

Digitized by Google

resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.—1st Edinburgh (the Queen's, City of Edinburgh Rifle Volunteer Brigade): The undermentioned Surgeons are granted the honorary rank of Surgeon-Major: R. J. B. Cunynghame and F. Cadell.—3rd Volunteer Battalion (the Essex Regiment): The undermentioned Surgeons are granted the honorary rank of Surgeon-Major: David MacEwan and Alexander Campbell.—1st Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon Henry Penfold, M.D., resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the Battalion on his retirement.—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Surgeon J. P. Purvis is granted the honorary rank of Surg.-Major.—3rd Volunteer Battalion, the Norfolk Regiment: Surgeon S. M. Hopson is granted the honorary rank of Surgeon-Major.—2nd Volunteer Battalion, the Northumberland Fusiliers: Surgeon A. Wilson is granted the honorary rank of Surgeon-Major.—1st Tower Hamlets (the Tower Hamlets Rifle Volunteer Brigade): John William Jackson, Gent., to be Acting Surgeon.—1st Volunteer Battalion, the Gordon Highlanders: Surgeon A. D. Davidson, M.D., is granted the honorary rank of Surgeon-Major.—1st Dumbartonshire: Surgeon P. F. Robertson, M.D., is granted the honorary rank of Surgeon-Major.—8th Lanarkshire (the Blythswood): The undermentioned Surgeons are granted the honorary rank of Surgeon-Major: A. Fergus, J. E. Brodie.—20th Middlesex (Artists'): James Cagney, Gent., M.A., M.D., to be Acting Surgeon.—24th Middlesex: Surgeon J. T. Powell, M.D., is granted the honorary rank of Surgeon-Major.—1st Volunteer Battalion, the Royal Warwickshire Regiment: Surgeon Thomas Thompson is granted the honorary rank of Surgeon-Major.

"Audi alteram partem."

THE BAROMETER AS A GUIDE TO HEALTH.

To the Editor of THE LANCET.

SIR,—A short while ago there came under my notice an abstract of the observations of Dr. M. A. Veeder of Lyons, New York, on the barometer as a guide to health. He says he has noted the occurrence of several deaths from apoplexy at times when rapid fluctuations of the atmospheric pressure were indicated by the barometer, and suggests the cause to be a difficulty in the adjustment of the volume and rate of the circulation of the blood to the varying atmospheric pressure upon the surface of the body, and consequent unusual strain on the weakened bloodvessels. He believes that at such times over-excitement, over-eating, improper clothing, and the like, act as determining causes of the rupture, and would warn persons who are advanced in years, or subject to symptoms that indicate an apoplectic tendency, to exercise great moderation in all things whenever the mercury is seen to be unusually active in its movements.

My attention was directed to this subject many years ago, and in the year 1872 I casually mentioned my opinions to Professor Gairdner of Glasgow, where I met him in consultation on a case of aphasia. I have often noticed a remarkable sequence of cases of cerebral and other hæmorrhages, and convulsions in children, during periods of great electrical disturbances and sudden and extreme fluctuations in the barometer. There is great difficulty, however, in obtaining an accurate reading of the barometer at the moment of seizure, the exact time of it being rarely noticed, and often considerable delay elapses before the message is brought to the medical man, during which the barometer may have made one of its sudden changes. On this account I have been unable to record many cases with the accuracy I could have wished. In two cases, however, I was more fortunate.

On Monday, March 1st, 1880, whilst spending the evening at the house of a friend, I received an urgent message to attend two patients who had been seized with cerebral hæmorrhage within a few seconds of one another. They were both past the middle period of life, one (a male) dying in a few hours, the other (a female) surviving for four days. My friend, who was in the habit of frequently consulting his barometer, examined it immediately after seeing me to the door, and found it standing at 28·10, the lowest reading he had ever seen it register. From the *Scotsman* of Tuesday, March 2nd, 1880, I extract the following notes of the storm:—"The following telegram was received at the East Coast Signal Stations from the Meteorological Office, London, yesterday: 'Deep depressions off north of Scotland; hoist north cone for west to north-west gale, Monday, 10.20 A.M.' A severe gale was experienced in Glasgow on Feb. 26th. The barometer by 10 A.M. stood at 28·8, a fall of 0·5 from Sunday. The barometer at Kirkwald registered 28·34, the lowest point registered since Nov. 22nd, 1877. At Longhope, Orkney, the barometer registered at midnight on Sunday 28·45, and at 9 A.M. on Monday 28·10, when broke forth the severest storm from the west witnessed since Nov. 16th, 1877. Between 2 and 3 P.M. peals of thunder were heard at Edinburgh."

I think that there can be no hesitation in connecting the cerebral hæmorrhage in the above cases with the sudden fall in the barometer. Indeed, so convinced am I of the connexion that for many years past I have been in the habit of advising my elderly patients to remain in-doors, and avoid intemperance in eating or drinking and over-physical or mental exertion, when the barometer suddenly rises or falls. Such sudden changes of atmospheric pressure must be attended with great danger to persons with weak hearts and diseased arteries. As none of our text-books, nor any of the authorities I have been able to consult, make any mention of the connexion between cerebral hæmorrhage and sudden variations of atmospheric pressure, I have cited the above cases in the hope that some of your contributors may be able to throw some light on the subject.

I am, Sir, yours sincerely,

WILLIAM F. MURRAY, M.D., F. & L.R.C.S.

Forfar, March, 1886.

P.S.—On Wednesday last, April 7th, the barometer suddenly sank to 28·4 in the evening, and remained at that point for a considerable time on Wednesday evening and Thursday morning. On my way to Perth on Thursday forenoon I ascertained from Mr. Robertson of Coupar Angus, who reports for the Meteorological Society, that his instrument had stood at exactly 28·4 the same evening and morning. On Wednesday night I had one case of convulsions in a child, and two cases of uterine hæmorrhage ending in abortion in the early months of pregnancy. In the *Dundee Advertiser* three cases of sudden death are reported to have occurred on the same evening within a radius of about twelve miles. They were all males—one seventy-two, one seventy-eight, and one above eighty. They had all been apparently in good health. This must be more than a mere coincidence.

SUPRA-PUBIC CYSTOTOMY.

To the Editor of THE LANCET.

SIR,—The danger of wounding the peritoneum in epicystotomy depends, I believe, to a great extent on the condition of the urine in the bladder. In a large proportion of cases of vesical calculus, bladder tumour, or cystitis (not induced by external agencies, dirty catheters, &c.), the urine is not septic. In some instances it is peculiarly suited to the growth of micro-organisms, so much so that, if passed into anything but a carefully purified vessel, it becomes putrid in a few hours. Even in these cases, as my valued teacher, Sir Joseph Lister, first pointed out, it is not necessarily septic when voided. I have now in my possession several specimens of urine from cases of cystitis and pyelitis, which I have preserved for a considerable time without any change having occurred in them (in one instance for more than six months), showing the absence of putrefactive organisms in the urine of these cases. These specimens have not been boiled, but were simply passed into purified vessels.

Numerous experiments on the lower animals, and cases of wound of the bladder in the human subject, during operation or otherwise, show that the contact of healthy urine with the peritoneum does not necessarily produce peritonitis. I believe that urine which contains muco-pus or pus, provided it is not septic, would be as little irritating to that membrane as healthy urine. From the examination of numerous subjects in the post-mortem theatre, I have satisfied myself that in a small proportion of them epi-

Digitized by Google

cystotomy could not have been performed without wounding the peritoneum or stripping that membrane off the bladder, as in M. Autal's case.

Major Tremaine has written in THE LANCET of April 10th, in reference to M. Polaillon's case: "Stranger yet that it [epicystotomy] should have been abandoned through dread of wounding the peritoneum; as this may occur without disaster, the following case will show, &c." This case supports my prediction at the British Medical Association meeting at Cardiff last year[1]—"That in a short time some malignant growths of the bladder with the portion of bladder wall to which they are attached, even when implicating the peritoneum, would be successfully removed, &c." At a meeting of the Bristol Medico-Chirurgical Society on Jan. 13th, I ventured to state my belief that in all cases in which the urine is not septic the peritoneum can be wounded with impunity in epi-cystotomy, provided strict antiseptic precautions are carried out. In those rare cases of low distribution of the peritoneum, complicated with a septic condition of urine in the bladder, it would be advisable to adopt the perineal route.

I am, Sir, yours obediently,

Clifton, Bristol, April 12th, 1886. W. J. PENNY, F.R.C.S.

NOTE ON ACUTE KERATITIS.

To the Editor of THE LANCET.

SIR,—In the many excellent treatises and manuals on diseases of the eye, the descriptions of the objective symptoms of acute inflammation of the cornea leave nothing to be desired in respect to minuteness and accuracy. Its constitutional relationship to syphilis and struma is also duly recorded and explained. But, so far as my reading extends, the acute constitutional disturbance with which it is not unfrequently accompanied in the case of children and some adolescents, also exceptionally among adults, has escaped the attention of writers. The local disease is ushered in by a febrile disturbance; the child has not only lost its appetite, but is thirsty and chilly, creeping up to the fire. The pulse is quick and easily compressed. It is under these conditions that small doses of tartarised antimony in combination with liquor ammoniæ acetatis prove useful. Our object, of course, is to restore the action of the skin; and until this has been effected, tonics, oils, or antisyphilitic remedies are useless and out of place. Quinine I have not found to reduce the febrile symptoms.—I am, Sir, yours faithfully,

Birmingham, March 31st, 1886. J. VOSE SOLOMON, F.R.C.S.

THE ROMAN SCHOOL ON M. PASTEUR.

(From our own Correspondent.)

THE universal interest now taken in the Pasteur treatment of hydrophobia is specially marked in Italy, where, according to the statistics recently collected by Mancini, cases of the disease occur in the proportion of 0·04 to every 10,000 of the inhabitants. Seldom, indeed, has the Reale Accademia Medica of Rome discussed any topic with more animation than the treatment in question, and a *résumé* of its proceedings on the 4th inst. will be found instructive in more than one phase of the subject. After Drs. Marchiafava and Brunelli had spoken, and Dr. Carruccio (the secretary of the Academy) had read Pasteur's letter on the necessity of forming a great international institution in Paris for the reception of hydrophobic cases of all countries, Professor Colasanti related the experience of Italian physicians who had watched Pasteur's methods in that physiologist's own laboratory, and, taking it as proved that of 500 hydrophobic patients under his care Pasteur had had but three failures, he contended that this result more than justified Rome in following the example of St. Petersburg, New York, Buda-Pest, and Berlin, and establishing a special hospital for the practice of the Pasteur treatment.

The next note struck was a slightly sceptical one. The President, Dr. Guido Baccelli, hoped that Pasteur's method would come out unscathed from the critical ordeal to which it was about to be subjected, but he counselled caution in accepting and still more in practising it, and reminded his audience that something very like the same experiments had already been carried on in Italy—notably, by Dr. Agostino Cappello of Tivoli, more than sixty years since. These experiments, though made with the scientific resources of 1820, had still an appreciable value, if only as suggesting that rabies of the second degree is not transmitted. In Pasteur's experiments a distinction must be drawn between prevention on the one hand and cure, properly so-called, on the other; and on this point further light is to be desired. If, as Cappello asserted, rabies of the second degree is not transmitted, then multitudes of those who flock to Pasteur are already safe from the disease without his inoculations. Dr. Baccelli thought that, without committing itself further, the Academy should send a competent representative to Paris to watch the treatment with the vigilance it required. At this stage of the proceedings two telegrams were read for Dr. Politini announcing the despatch of a paper giving details as to the inoculation of the virus practised by him for a series of years.

Then followed an encounter between Dr. Colasanti and Professor Francesco Scalzi (Cesalpino's apologist), the former maintaining that Cappello's experiments differed from those of Pasteur, in that Cappello inoculated with the saliva of the hydrophobic dog, while the superior science of the Frenchman saw that the virus resides in the medulla spinalis, and used this, specially prepared, for the inoculations. Dr. Scalzi rebutted this charge, till an accurate acccount of Cappello's papers, as read before the Accademia dei Lincei in 1823 and 1826, had to be produced. This was done by Dr. Carruccio, who, recapitulating Cappello's attempt to neutralise the hyprophobic virus by the canine saliva, read the author's conclusion that, "from numerous experiments made on dogs and cats, he is satisfied that the rabies, after its first passage into another animal, not excluding those of the species *canis*, no longer preserves its venefic force, but is quite destroyed, and hence is not reproducible as contagious maladies are reproduced." Cappello, it seems, was able to predict with singular accuracy what cases bitten by a mad dog would die and what would recover—his thesis being that rabies of the first degree is alone capable of transmission, while that of the second (that is, one remove from the original mad dog) is not. Dr. Gualdi showed that Cappello's observations were most accurate, and were largely confirmed in France, where Brachit in 1840 and Regnault in 1844 published a long series of cases to prove that the hydrophobic virus in its second and third passage had lost its contagious virulence. As to Pasteur's statistics, Dr. Gualdi contended that their scientific value was often more than doubtful, because many patients subjected to the treatment had already been cauterised immediately after the bite; that others had been bitten in parts covered with their clothes; while very few, bitten on the naked skin, had not received some sort of therapeutic aid at the time. He mentioned what had occurred in the hospital of S. Gallicano, where a family of seven had been brought, all bitten by the same hydrophobic dog. Of these, three had their garments torn and the skin divided, but they escaped; two bitten on the bare skin died; and the remaining two, who had also been bitten on the bare skin, lived. He concluded by saying that if Cappello's observations and well-known practice had not been correct, the canine race in the Roman Campagna would have been stamped out long ago.

Dr. Bastianelli, in confirmation of the efficacy of clothes in preserving those bitten by mad dogs from the virus, cited the case of a countryman who, after a genuine hydrophobic bite, escaped, while his sister, who mended his trousers torn by the animal's teeth, and who had imprudently drawn through her teeth the thread which had been in contact with the saliva-stained garment, died of hydrophobia. Professor Marchiafava admitted the sagacity and diligence of Dr. Agostino Cappello, but dissented from Dr. Gualdi as to the validity of Pasteur's experiments, which, he said, rested on the grand impregnable principle of the attenuation of the virus, a principle demonstrated in the prevention of small-pox, carbuncle, the cholera of fowls, the red disease of pigs, &c., and established by the fifty animals which Pasteur had rendered scatheless from the bites of hydrophobic dogs. He was followed by Dr. Piermarini, who read from a former bulletin of the Academy (1881) an extract from a paper by himself to show the protective influence clothes exercise against the passage of the virus into the wounds inflicted by mad dogs; and the President, Dr. Baccelli, summed up the debate in a few succinct periods, in accordance with which was framed and unanimously voted the order of the day already given in THE LANCET.

Rome, April 9th.

MANCHESTER.

(From our own Correspondent.)

CASES OF POISONING.

Two cases of poisoning under unusual circumstances have lately occurred here. Two patients of a medical man in Openshaw, one a woman aged thirty-nine, and the other an infant of five months, had medicine made up for them on the same day by his assistant, and both died with symptoms of narcotic poisoning, the woman within twelve hours and the infant on the second day after. From the evidence at the inquest, it was found that in both cases the medicine supplied contained morphia—to the extent of 18¾ grs. per oz. in that supplied to the woman, and nearly double the amount in that supplied to the infant, though in the latter case the dispenser denied having used either morphia or opium. The verdict in the case of the woman was death from opium poisoning owing to negligence on the part of the dispenser; in the second, although the evidence was, if anything, less strong, a verdict of manslaughter was returned; but on the following day evidence was adduced in the police-court that death in this case might have resulted from disease of the lungs, and the stipendiary therefore refused to commit the defendant for trial.

SIR H. ROSCOE.

Sir Henry Roscoe, as one of our members of Parliament, has already brought his special scientific knowledge to bear upon matters before the Legislature, and was largely instrumental in getting Mr. Hastings' "Bill for the Purification of Rivers" rejected upon its second reading, as being under present conditions impracticable, and so hostile to the interests of manufacturers in this part of the country that, if passed, it would impose such restrictions and burdens upon many industries as would render it impossible to carry them on. Still later, he has been placed upon a committee charged with the duty of endeavouring to discover the cause of, and remedy for, the odours which so often offend the nostrils of our legislators within the House of Commons.

ST. MARY'S AND THE LOCK HOSPITALS.

A suggestion was thrown out at the annual meeting of St. Mary's Hospital that the time had arrived when an endeavour should be made to obtain a better and more modern building for this important charity, and now an appeal is before the public asking subscriptions for the same; but it is questionable whether the time is opportune, and at present the response has not been so encouraging as could have been desired. At the annual meeting of the Lock Hospital, at which the Dean of Manchester presided, it was stated that by dint of the most rigid economy the expenditure had been kept within the income, though this unobtrusive charity is perforce of limited funds compelled to keep one-half or more of its beds empty. That the management has, indeed, been careful is shown by the fact that the cost of food was less than ninepence per patient per day. The skin department of this institution also suffers from want of funds. It is now carried on in a separate building, and some good work is, as far as means will allow, being carried on there by Dr. Brooke.

FREE BREAKFASTS.

During the severity of the past season a scheme, which cannot be too highly commended, has been carried out under the auspices of the School Board authorities of providing free breakfasts to those poor children who were known to belong to parents in necessitous circumstances. It was stated at the last meeting of the School Board that 2500 children has thus been fed at a cost of four-fifths of a penny per head. The funds for providing the same were from voluntary contributions.

OPEN SPACES.

Our corporation has of late come in for a goodly share of criticism, not to say abuse, from certain quarters, but it cannot be denied that in many ways they endeavour to look after the interests of the health of the community. The Council has lately had under consideration the question of provision of open spaces, and a subcommittee has been appointed to consider and report as to the extent of its powers, and how best it may be brought about that, in laying out for building purposes land in the suburbs of the city, a due proportion shall be reserved open and free for the use of the inhabitants. Again, the Health Committee has for some time past seriously taken in hand the subject of unhealthy dwellings and homes of the poor, and at the Council meeting held recently a report was presented thereon, but it met with considerable opposition, the cry of vested interests being, as usual, raised against it, and the discussion was postponed.

Prosecutions for offences under the Adulteration Act are frequent; milk, butter, and coffee have all received attention, and the latest delinquents have been the bakers. In one case alum to the extent of forty grains per 4lb. loaf was discovered, and the offender fined £5 and costs.

The compensation to the Local Board officials of Bradford and Rusholme upon the amalgamation of these townships with the city has, after much delay caused by opposition from some members of the corporation, been settled. The two medical officers of health will receive annuities of £8 and £24 per annum respectively.

Sir Wm. Roberts has been placed upon the Commission of the Peace for Merionethshire. In this instance, at least, it cannot be said that the honour has been conferred for political motives, for few men have associated themselves less with politics than Sir William.

Manchester, April 12th.

LIVERPOOL.

(From our own Correspondent.)

THE QUEEN'S VISIT.

THE approaching visit of Her Majesty to Liverpool and her residence there on the 11th and 12th proximo are being looked forward to with much interest. It will be her second visit to this city, her first having taken place in 1851, when she was accompanied by the late Prince Consort. Thirty-five years is a sufficiently long interval to cause great changes in the ranks of the medical profession in any locality, and but comparatively few of the present local medical practitioners can remember Her Majesty's first visit, while many who were then living and practising have passed away. The Exhibition, commonly known by its short title of the "Shipperies," will be held upon the site where it was proposed to erect the hospital for infectious diseases, but the site was condemned as unsuitable by the profession and the public in consequence of its close proximity to a large and extremely noisy railway junction.

THE LADIES' CHARITY AND LYING-IN HOSPITAL.

Dr. Glynn Whittle has been elected surgeon to the hospital, in the place of the late Dr. R. A. H. Wood. Dr. Whittle, who has very high qualifications, has been one of the district surgeons of the charity. The hospital will have in him a most useful medical officer, and the present staff a very genial colleague.

THE ROYAL SOUTHERN HOSPITAL.

Mr. Paul performed the Tagliacotian operation for an ulcer of the leg at the Royal Southern Hospital on Tuesday last. The patient was an otherwise healthy young man. He had a large ulcer in the usual position, which, probably on account of the large amount of cicatrix over the bone, always broke down after it had healed directly he got about. A broad flap of skin was dissected up from the opposite calf and attached to the freshened edges of the ulcer, the legs being fixed in suitable apposition by a plaster-of-Paris bandage. This is the sixth operation of the kind, and so far all have succeeded. In the children's ward is a case of rather severe stab in the back in a boy of eleven. This is the second example of the use of the knife amongst mere children which has come under the care of Mr. Paul within the last six months. The cause here was a religious party fight. The police will do well to prevent the spread of this most unfortunate tendency amongst boys.

ASSAULTS UPON AND BY POLICE CONSTABLES.

In so large a city as this it is only to be expected that there should be numerous assaults upon the police by the drunken and savage roughs to be found in every large community. Such cases, when clearly proved, are generally severely punished. It occasionally happens, however, that policemen are themselves guilty of violence towards prisoners in their custody, which is not surprising, seeing that in so large a force as 1300 men there must of necessity

Digitized by Google

be a few "black sheep." Formerly it was not uncommon for these cases to be hushed up, the complainant being induced for a consideration not to appear. Captain Nott-Bower, the present head constable, has most resolutely set his face against this practice, and has resolved that every case shall be fully inquired into by the magistrates as well as by himself and the Watch Committee. His resolution is much to be commended, as it is only by this means that perfect confidence can be felt in the police.

Liverpool, April 14th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

UNIVERSITY OF DURHAM.

THE number of candidates for the approaching examinations on the 19th and 26th of this month is as follows:—1st M.B. (under the new regulations), twenty-eight entries; Sanitary Science, certificate for proficiency in, two; 1st M.B. (old regulations), twenty-six; 2nd M.B. (new regulations), thirty-two. In the 1st M.B. (old regulations) and 2nd M.B. (new regulations), Mr. Frederick Treves is associated as foreign examiner in Anatomy with Dr. Mears; Mr. Golding-Bird as the foreign examiner in Physiology, with Dr. Thomas Oliver. Mr. McBean is examiner in Materia Medica in the 2nd M.B. (new regulations). This gentleman, I believe, will this summer give lectures on Therapeutics as well as Materia Medica, Dr. Barron having retired from the chair of Therapeutics.

PHOSPHORUS-POISONING.

Another case of phosphorus-poisoning from lucifer matches, in a man, was admitted to the infirmary about ten days since. His symptoms were from the first mild. This makes the sixth or seventh case admitted into that institution during the last four months.

NEWCASTLE CHEST HOSPITAL.

The full title of this institution is the Northern Counties Hospital for Diseases of the Chest, and it held its annual meeting on the 5th ult. The mayor presided, and spoke of the great benefit of hospitals to the public. The year, on the whole, had been a successful one; 554 patients had been treated. This institution, like others doing good work, had felt the pressure of the times in the diminished subscriptions of the past year. The committee regretted the resignation of Dr. J. C. Murray, who had removed to Stranraer, his place being filled by Dr. F. C. Coley of Newcastle.

SMALL-POX AT WEST HARTLEPOOL.

At a late special meeting of the Hartlepool Port Sanitary Authority Dr. Biggart reported that there were now twenty-two cases accommodated in the tents. It was decided to ask the Commissioners to grant the authority the use of a portion of the waggon works.

NEWCASTLE INFIRMARY.

The Committee of the Newcastle Infirmary have issued an appeal to the public for increased support, stating that the present annual expenditure is £13,949, and its receipts only £10,437, and that if its work is to continue £3000 will have to be added to the yearly income. At present the banking account is overdrawn to the extent of £3000. One of the grounds of appeal is that "the infirmary is really the parent of all the numerous medical charities, and that the increase in the number of such charities has not diminished the work of the infirmary, though without doubt it has materially lessened the support which would have been given to it." Though the number of patients has increased from 14,294 in 1863 to 39,360 in 1885, the amount of subscriptions have only increased during this time £500 per annum. On the other hand, Mr. C. S. Jeaffreson, who was formerly connected with the Newcastle Infirmary, but is now one of the surgeons to the Eye Infirmary, writes to one of our local papers pointing out that the statement that the infirmary is the parent of all the medical charities of this city is entirely at variance with facts. Mr. Jeaffreson says—"None will deny that a very large amount of useful and valuable work is done by the infirmary, but that those who best know the workings of our medical charitable system will agree with me that with due economy, proper management, and proper supervision of the class of patients who receive the benefits of the charity, £10,500 a year should amply suffice for its requirements."

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

IN addition to the names already mentioned as having recently been elected Honorary Fellows of the Royal College of Surgeons in Ireland, may be added that of Sir Spencer Wells, whom the Council at their meeting last week duly elected to that honour, and I am informed that he will be present at the banquet to be given by Sir Charles Cameron, the President, on the 28th inst. A History of the College, which the President has been engaged upon for a considerable time past, is now almost finished, and it is hoped that a copy of the work will be in time for the ceremony on the 28th inst. By the kindness of Mr. Farrell, the well-known sculptor of this city, I have had an opportunity of seeing his statue of Mr. Dease, one of the founders of the College. It is an excellent work of art, and is sure to give every satisfaction to all interested in the matter.

ROYAL UNIVERSITY OF IRELAND.

A deputation from the Senate, which included Lord Emly, the Vice-Chancellor, had an interview with the Lord-Lieutenant last week, for the purpose of asking his Excellency to impress on the Government the necessity of granting a sum of £10,000 for providing laboratories and scientific apparatus for the new buildings now being erected. A deputation from the University, with a similar object, some time since had an interview with the Financial Secretary to the Treasury, without any result. Lord Emly stated that when the University was founded it was understood the buildings should be provided by Government with all necessary appliances, and that, in point of fact, the buildings recently erected by the Government would be perfectly useless, as the University could not furnish the necessary apparatus out of the grant of £20,000 a year at present allowed. His Excellency said that the view of the Government appeared to be that the endowment was ample, and that all University appliances could be provided out of it. However, if the Senate would state their views on paper, he would forward them to the Treasury, with an endorsement as to his own opinions.

OUTBREAK OF FAMINE FEVER IN LISMORE UNION.

Last week five cases of famine fever were admitted to Lismore Fever Hospital from the district of Cappoquin, and the following remarks, as bearing on the subject, may be of interest. During the winter severe distress prevailed in Cappoquin district owing to the want of employment among the labouring classes, and, in consequence, the guardians instructed their engineer to report as to the condition of the labouring poor, and, if necessary, to carry out any sanitary works that might be required. He reported that he found many of the labourers without a morsel of food, and employment was therefore given to about fifty for a few weeks, and then ceased, as the guardians could not open up special work to cope with the distress without the consent of the Local Government Board. However, the labourers were placed on half out-door relief, and consequently many families existed in a state bordering on starvation on an allowance of one shilling per week. The medical officer of the union, Dr. Dennehy, brought the matter of the outbreak of fever before the guardians, and it has been stated that an inspector of the Local Government Board has been sent to inquire into the state of the district. So far as has been ascertained, the fever is confined to the locality where it originated, and by proper precautions and by additional employment being given to those most in need, it is expected that the distress will be alleviated. No additional cases, it is believed, have occurred.

BOARDING OUT OF PAUPER CHILDREN.

This procedure has generally been attended with satisfactory results not alone to the children but also to the ratepayers, as the nurses almost invariably adopted the children placed under their care. Exceptions, however, occasionally occur, and last week an instance of the kind was reported at a meeting of the guardians of the North Dublin Union. It was discovered that a woman to whom two children had recently been given out of the workhouse to nurse and rear had thirteen additional children who were living in a cottage of only two apartments, and very properly the children in question were at once removed from her custody.

Digitized by Google

NORTH DUBLIN UNION.

A deputation from the guardians recently waited on the Governors of the Richmond Lunatic Asylum in order to obtain a capitation grant of four shillings for the pauper lunatics sent into the workhouse from the asylum under the 9th section of 38th and 39th Vic., cap. 67. The governors of the asylum, however, were of opinion that these lunatics were sent in under the provisions of the 11th section, and not of the 9th, of the Act referred to, and declined to make any payment or to enter into the matter until the guardians could produce the consent of the Local Government Board and of the Lunacy Inspectors to the claim. As the sum claimed is £1600, and as the South Dublin Union are endeavouring to establish a similar demand, the matter will be again brought forward, and doubtless will ultimately be granted. The refusal of the governors to acknowledge their indebtedness is said to arise from the fact that the present accommodation and attendance given to harmless lunatics sent into the workhouse is very deficient.

Dublin, April 13th.

PARIS.

(From our own Correspondent.)

DEATH OF PROFESSOR BOUCHARDAT.

THIS eminent physician expired on Thursday, the 8th inst., at his residence in Paris, in the eightieth year of his age. He died from extreme exhaustion resulting from great depression of spirits, by which he had become affected since his retirement from the Professorship of Hygiene, which he held at the Paris Faculty of Medicine since 1852. For some time before his retirement he became rather deaf, in consequence of which he was obliged to refrain from taking part at the examinations for the Doctorate. He was otherwise in good health, but his forced retirement from an active life so preyed on his mind that he gradually broke down and nothing seemed to renovate him. Professor Bouchardat did not do much in the way of practice, but devoted his whole time to the improvement of his office and to scientific and literary work. He wrote a good deal, and the mere enumeration of his works would fill some columns of THE LANCET. He wrote principally on Materia Medica, Pharmacology, and Hygiene. The works bearing these titles are the text-books of the Paris Faculty, and will probably remain so for some years to come. His "Annuaire de Thérapeutique," which was commenced forty-five years ago, and his "Nouveau Formulaire Magistral," which has passed through nineteen editions, are well known to the profession. He took his degree in 1832, and was soon after promoted to agrégé, but, as he evinced a predilection for pharmacology, he was appointed pharmacien to the hospitals, in which capacity he was attached to the Hôtel Dieu from 1834 to 1853. He was a member of the Academy of Medicine since 1850, and became its president in 1866. He was also an officer of the Legion of Honour. He leaves two sons, one of whom is a surgeon-major in the French Army, and the other is a professor at the School of Pharmacy. The funeral of the deceased physician took place on Saturday last, in the presence of a large concourse of persons of all ranks in and out of the profession, among whom were many of his patients of both sexes; and to give your readers an idea of the number that attended I may mention that the old cathedral of Notre Dame, his parish church, and where the service was performed, was at least half full. Though his desire was that his funeral should be as simple as possible and without any official pomp, yet the members of the Faculty and the Academy of Medicine considered it their duty to attend in a body, though not in their official garbs.

DEATH OF DR. AMÉDÉE FORGET.

I have also to report the death of Dr. Amédée Forget, which took place on Sunday, the 11th inst., in the seventy-fifth year of his age. He was for many years in failing health, which induced him to retire from practice. He was once president of the Société de Médecine of Paris, and at his death was consulting surgeon to the Institution of the Legion of Honour, of which he was also an officer. His medical knowledge was very extensive, and he more than once received a prize from the institute in recognition of the value of his works.

A VENERABLE SAVANT.

There are three men whose names have been for some time almost constantly before the public: M. Pasteur, for his remarkable discoveries; M. de Lesseps, as a pioneer of civilisation; and M. Chevreul, as an illustrious chemist, academician, and centenarian. M. Chevreul styles himself the "doyen des étudiants." In order to celebrate his hundredth birthday, which is on Aug. 31st next, the various learned societies of France propose having a public demonstration in his honour. It is also proposed to celebrate the centenary of the introduction of the potato into Europe by Parmentier in the form of a banquet, which will be presided over by the three illustrious men above named, and on which occasion "la pomme de terre" will be the "plat d'honneur."

M. PASTEUR.

The Stanley Club at Paris gave this evening a dinner to M. Pasteur, which was presided over by the American Minister. In replying to the toast of the evening, M. Pasteur, referring to his system of treatment by inoculation, said that the insults of anti-vaccinators and anti-vivisectors, the hesitation, temporising, or jealousy of newspapers, were immaterial to him. He could afford to wait with confidence, albeit there were some who waited with the hope of his failure. I may here mention that the Sultan of Turkey has decided upon sending a mission to Paris composed of two medical men and a veterinary surgeon to study the anti-rabic method of M. Pasteur. One of the party is the bearer of the Grand Cordon of the Medjidieh and a sum of 10,000 fr., which are to be given to M. Pasteur in the name of the Sultan, the latter being intended for the Pasteur Institute. At the last meeting of the Société d'Hygiène, M. Pasteur announced the death of another patient (which will be the third) of the first Russian party from Smolensk. He died on April 2nd, at the Hôtel Dieu, with the symptoms of hydrophobia. M. Pasteur is by no means discouraged by these deaths; he will only be induced to study more particularly the phenomena attending the bites of wolves, which he considers more grave than those of dogs or other animals.

Paris, April 14th.

MEDICAL NOTES IN PARLIAMENT.

Contagious Diseases Acts Repeal (No. 2) Bill.

IN the House of Lords on the 9th inst., Lord Sandhurst, in moving the second reading of this Bill, said that it was intended simply to carry out public opinion, which had of late years gone in one direction—viz., in that of the repeal of the Acts. Viscount Cranbrook agreed that when Acts were inoperative they should be removed from the Statute Book, but protested against the idea of local authorities being called on to undertake a duty which the Legislature refused to carry out. The motion was then agreed to.

On the 12th inst. the Bill passed through Committee, and on the 13th inst. it was read a third time and passed.

The Idiots Bill.

On the 12th inst. this Bill was read a third time.

The Medical Act, 1858.

In the House of Commons on the 14th inst., a Bill to amend the Medical Act, 1858, was brought in by Mr. Morgan Howard, and read a first time.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 8th inst., and when eligible will be admitted to the Pass Examination:—

W. H. L. Copeland and H. S. Tuppen, Cambridge University and St. Thomas's Hospital; Montague Tench, J. Kynaston Couch, J. A. T. Woodgate, and F. G. Parsons, Middlesex Hospital; A. E. Norburn, R. Devereux Mothersole, and C. Price-Jones, Guy's Hospital; A. H. Cheatle, King's College Hospital; J. England Brogden, St. Bartholomew's Hospital; W. S. Sharpe, G. Coleridge Davis, and Alexander Lewers, St. Mary's Hospital; F. Grange, Charing-cross Hospital; W. B. Ransom, Cambridge and University College Hospital; W. Harris Best, London Hospital; A. J. Adkins and C. J. Martin, St. Thomas's Hospital.

ANATOMY ONLY.—H. Lee Green, Toronto University; John Griffith, St. Mary's Hospital; A. H. Blunt, St. Thomas's Hospital.

PHYSIOLOGY ONLY.—P. W. Turnor, St. George's Hospital; P. Christian de Wet, St. Thomas's Hospital.

Digitized by Google

Passed on the 9th inst.:—

ANATOMY AND PHYSIOLOGY.—W. L. Liston, Owens College and St. Mary's Hospital; J. Mansbridge and William Morrison, Charing-cross Hospital; E. T. Larkam and J. W. Gill, Middlesex Hospital; F. R. P. Taylor, Westminster Hospital; C. S. Dowdell, University College Hospital; Arthur Fagan, London Hospital; A. E. P. Hughes, St. Thomas's Hospital.

ANATOMY ONLY.—E. D. Kell, University College Hospital; E. A. Nicholletts, London Hospital; Herbert Fraser, St. Thomas's Hospital; Reginald Hedley and James Smith, Bristol Medical School; Mallard Martin, Sheffield Medical School; John Robertson, Guy's Hospital.

PHYSIOLOGY ONLY.—R. W. Anderson, University College Hospital; A. E. Howse, King's College Hospital; J. M. Fry, Westminster Hospital; D. J. Aaron, London and Madras; A. W. Gray and R. S. M. Groves, Birmingham School of Medicine; P. R. Hird, Yorkshire College, Leeds; W. J. Watkins, Bristol Medical School; J. A. Wood, University College Hospital.

The Library of the College of Surgeons will be closed on Friday and Saturday, the 16th and 17th inst., for the purposes of the Final Examination for the Membership, 280 candidates having entered for this examination.

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS.—The following gentlemen passed their Second Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 5th inst., and when eligible will be admitted to the Pass Examination:—

J. E. Briscoe, Yorkshire College, Leeds; S. W. Morgan, Hedley Hill, H. F. Mole, and J. T. Grey, Bristol Medical School; Thomas Watts, Oliver Eaton, Patrick Rowan, J. H. Barker, B. Wiseman, J. Halliwell, Aubrey Conway, J. A. Cooke, and E. H. Robinson, Owens College, Manchester; S. Farrage Gibbs, H. N. Crossley, H. E. Knight, C. H. Roberts, and F. B. A. Colby, St. Bartholomew's Hospital; R. A. Bremner and J. E. F. Hosking, Guy's Hospital; H. E. Skyrme and Samuel Davey, London Hospital; A. S. Milner and B. F. F. Jackson, Charing-cross Hospital; G. E. Weary and J. Tertius Clarke, St. Thomas's Hospital; R. T. Gravely, St. Mary's Hospital.

ANATOMY ONLY.—A. C. Gaskin and H. C. Titterton, Owens College, Manchester.

PHYSIOLOGY ONLY.—H. K. Ramsden, Owens College, Manchester; Masha A. Khan and E. J. Reynolds, London Hospital; G. H. Humphreys, St. Bartholomew's Hospital.

Passed on the 7th inst.:—

ANATOMY AND PHYSIOLOGY.—F. E. Forward, H. H. Hulbert, and T. P. Cowen, St. Thomas's Hospital; E. Beddoe Hulbert and Harry Davis, University College Hospital; J. T. Clapham, W. G. Willoughby, Ransom Pickard, W. F. Cholmeley, Bedford Price, A. R. Poulter, G. H. D. Robinson, H. G. G. Cook, and C. Evelyn Ormerod, St. Bartholomew's Hospital; Percy J. Kingston, Oakley E. Higgens, William Henry, and F. W. Lewitt, St. Mary's Hospital; Maxwell Le Cronier, W. Marshall Davidson, and H. Higgins, St. George's Hospital; H. C. H. Parham, P. J. Duncan, and E. J. Appleton, Charing-cross Hospital; T. Boswall Beach, King's College Hospital; Louis Beckett, London Hospital.

ANATOMY ONLY.—Colin E. W. Bennett, Middlesex Hospital.

PHYSIOLOGY ONLY.—Frederick Bell, St. Bartholomew's Hospital; R. H. Tompsett and Harry Gervis, St. Thomas's Hospital.

Passed on the 8th inst.:—

ANATOMY ONLY.—Cyril Ogle and W. S. Heberden, St. George's Hospital; R. J. Hutchinson, London Hospital.

Passed on the 12th inst:—

ANATOMY AND PHYSIOLOGY.—E. A. Edelsten, B. C. Oldham, Robert H. Elliot, Alfred Willson, J. C. Shaw, A. W. L. Jones, S. Browning Smith, C. E. Hutt, and J. A. Hayward, St. Bartholomew's Hospital; L. H. Bennett and C. H. Duncan Morland, St. George's Hospital; E. A. Falkner and B. H. Deare, Middlesex Hospital; J. R. Plant, Westminster Hospital; J. W. Higginson, University College Hospital; P. C. Thomas and E. A. Roberts, St. Thomas's Hospital; A. E. Baker, Charing-cross Hospital; H. S. Ballance, King's College Hospital; Arthur M. Hickley, St. Mary's Hospital; H. B. Bolus, Guy's Hospital; W. Soltan Fenwick, London Hospital.

ANATOMY ONLY.—P. Napier Jones, St. Mary's Hospital; E. R. Streeten, St. George's Hospital; F. E. Marshall, King's College Hospital.

PHYSIOLOGY ONLY.—A. Talman Ilott, Charing-cross Hospital; E. D. Y. Pode and F. R. S. Milton, St. Thomas's Hospital; A. C. Davies, University College Hospital; Charles Spurrell, Guy's Hospital.

Passed on the 13th inst., and when eligible will be admitted to the Final Examination:—

ANATOMY AND PHYSIOLOGY.—W. J. Foster, St. Mary's Hospital; J. Gilbert Ogle, E. M. R. Bryant, and E. G. Carpenter, St. Bartholomew's Hospital; A. N. Boycott, H. G. Turney, and F. C. Abbott, St. Thomas's Hospital; F. Bernard Betts, Westminster Hospital; A. B. Watson, J. Ring, J. A. Hutton, and G. Colborne, Middlesex Hospital; B. M. H. Rogers and Arthur Gale, University College Hospital; K. Worsley Poole, F. S. Harris, and Ernest Burchell, London Hospital; R. T. Hewlett, King's College Hospital; H. W. Clarke, Charing-cross Hospital.

ANATOMY ONLY.—W. Metcalfe and Lennard Cutler, St. George's Hospital; H. W. Reynolds and Frank T. Long, St. Bartholomew's Hospital; Walter Gibson, Guy's Hospital; Edgar H. Strong and W. V. Eaves, University College Hospital.

PHYSIOLOGY ONLY.—P. T. B. Beale, King's College Hospital; D. Lawson, and C. L. Howe, Middlesex Hospital; Charles Wilson, William Thomas, W. H. Coates, and Stuart R. Blake, London Hospital; N. A. A. Trenow, St. George's Hospital; Arthur Boulton, Charing-cross Hospital; Francis Dugon, Guy's Hospital; D. D'Auvergne Wright, University College Hospital.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 8th inst.:—

Burnside, Eustace Augustus, Richmond-road, Bayswater.
Pain, Francis, M.R.C.S., Stratfield House, Thurlow-park-road, Dulwich.
Whitten, Samuel, Fairfield-road, Bow.

On the same day the following gentleman passed his Primary Professional Examination:—

Conolly, Charles Hamilton, St. Bartholomew's Hospital.

THE library of the Royal Medical and Chirurgical Society will be closed from Good Friday to Easter Monday, both days inclusive.

MR. M. C. SOUTTER, M.R.C.S., A.K.C. Lond., of Finsbury Park, has been elected a member of the South Hornsey Local Board of Health.

ANTI-VACCINATION AT LEICESTER.—Of the thirty-eight guardians elected for the Leicester board this week twenty-six are stated to be pledged to resist the operation of the Vaccination Acts.

THE Duke of Connaught presided on the 14th inst. at the festival dinner in aid of the funds of the British Home for Incurables. During the evening subscriptions amounting to about £1000 were announced.

VACCINATION GRANTS.—Mr. Garrett Horder, of Crockherbtown; Mr. R. G. Price, of Treorchy; and Mr. Geo. Lowther, of Kingston-upon-Hull (fifth time), have received the Government grant for efficient vaccination in their respective districts.

A NEW sanatorium for infectious diseases, erected at Alcester by public subscription as a memorial to the late Marquis of Hertford, was publicly opened on Saturday last by the Marchioness of Hertford, in the presence of a distinguished company.

AMONGST the guests present at a banquet given at the Mansion House by the Lord Mayor, on the 13th inst., to the representatives of the learned societies, were Sir James and Lady Paget, Mr. W. S. Savory (President of the Royal College of Surgeons), Sir Andrew and Lady Clark, Sir William Gull, Dr. B. W. Richardson, and Dr. Edwards.

MEASLES IN BERLIN.—An epidemic of measles is, it is reported, prevailing to a considerable extent amongst the upper classes of Berlin, one of the latest sufferers being the Crown Prince of Germany. His Highness's age being fifty-four, the disease cannot be considered entirely free from danger, but fortunately the attack appears to be of a mild character.

SANITARY ASSURANCE ASSOCIATION.—At a meeting of the Council on the 12th inst., General Sir Peter S. Lumsden, C.B., C.S.I., G.C.B., was elected a member of the Executive Council on the motion of Sir Joseph Fayrer, F.R.S. Mr. Mark H. Judge, A.R.I.B.A., submitted a draft Bill for the better sanitation of dwellings. This draft was referred to a Committee for consideration and report. One of the provisions of the proposed Bill is as follows:—"After January 1st, 1888, it shall not be lawful for any dwelling-house, school, hotel, or other public building used, or intended to be used as such, to be so used unless and until a certificate has been deposited with the local authority in accordance with the provisions of this Act."

PRESENTATIONS.—In recognition of his having given two courses of instruction in ambulance work to the members of the Leith police force during the past winter, Dr. O. H. Garland has recently been presented with a silver cigarette case by his pupils.—On the 3rd inst., at a meeting presided over by Sir Andrew Clark, a testimonial, consisting of a timepiece and an illuminated address, was presented to Dr. Dundas Grant in recognition of his services as chairman of the late East London Industrial Exhibition.—On the 4th inst. the boys of Marlborough College presented Dr. Fergus with a silver tea service, he having, as previously intimated, resigned his post as medical officer of the College after a tenure of thirty-seven years.—On the 8th inst., previous to his departure for Cape Colony, Mr. Davidson was presented by several of the inhabitants of Alnwick with an illuminated address, a valuable case of surgical instruments, and a purse of gold as a mark of their appreciation of the manner in which he had performed the duties of medical officer of health of the town and house surgeon to the local infirmary.—On the 5th inst. Dr. Lionel Weatherly was presented by the working men and women of Portishead with a timepiece and an address, on the occasion of his quitting the neighbourhood.

Digitized by Google

AT the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on the 13th inst., T. Russel Pickthorn, Esq., Inspector-General, in the chair, the sum of £64 was distributed among the several applicants.

THE SEWAGE QUESTION.—The treatment of sewage formed the subject of a paper introduced at the Society of Arts on the 14th inst. by Dr. Meymott Tidy. The paper was exceedingly voluminous, and although the author did not present it in more than outline, the reading of it occupied the entire morning, discussion being postponed until a future date. Sir Frederick Abel presided, and there was a large attendance of engineers, chemists, and others interested in the question.

THE HOSPITALS ASSOCIATION.—The annual meeting of the members of this Association was held on the 14th inst., Sir Andrew Clark presiding. The report, which was read by Mr. F. Almond Hunt, and ultimately adopted by the meeting, divided the work carried out by the Association into three main heads—the collection, classification, and arrangement of figures and facts bearing upon the administration of hospitals and asylums, and their publication; the appointment of sectional committees; and the dissemination of information likely to benefit hospital economy. Mr. H. Burdett, in moving the adoption of the report, detailed the progress which is being made by the Association. Amongst the other speakers were Mr. Pease, M.P., Dr. Bristowe, and Major-General Keating. Sir Andrew Clark was elected president of the Association.

THE LIVERPOOL LOCK HOSPITAL.—For reasons more obvious than logical, lock hospitals receive few or none of the gifts so lavishly showered upon other hospitals in the shape of books, engravings, prints, flowers, &c. It is therefore very gratifying to give an exception to this general rule. Some years ago, at the request of Mr. F. W. Lowndes, one of the surgeons to the Liverpool Lock Hospital, the proprietors of the *Graphic* forwarded to the hospital a large parcel of back numbers with separate large engravings, both coloured and plain. With the assistance of some influential friends these were framed and glazed, and were sufficient to cover the walls of the female wards. Recently, Mr. Lowndes received another parcel from the same donors, with engravings for the male wards.

SOCIAL SCIENCE ASSOCIATION.—At a special general meeting of this Association held on Wednesday, the 14th inst. (Mr. Hastings, M.P., in the chair), a motion, of which due notice had been given, for the dissolution of the Association and its amalgamation with some other body, and an amendment recommending a continuance of the annual Congresses having been considered and ultimately withdrawn, it was unanimously resolved, on the motion of Mr. Hastings, M.P., seconded by Mr. Mark H. Judge: "That the action of the Association be suspended for the present, and that a committee of twelve be now appointed to reduce within the smallest practicable limits the expenditure, and to clear off the existing liabilities; to dispose of any of the books or other property of the Association; to call the Society into active existence whenever the circumstances of the time may seem favourable; and to report to a special general meeting of the Association on a requisition signed by at least twenty members."

ASSOCIATION OF MEDICAL PRACTITIONERS QUALIFIED IN SANITARY SCIENCE.—At a largely attended meeting held on the 9th instant, the above Association was inaugurated. It was proposed by Dr. H. F. Parsons, and seconded by Dr. Louis Parkes, that the body be called "The Association of Medical Practitioners qualified in Sanitary Science," which was carried unanimously. The main object of the Association is to obtain the registration of sanitary science degrees and certificates of universities and corporations whose medical degrees and licences are at present registrable. Among others who have joined the Executive Council are the following:—P. Hinckes Bird, F.R.C.S. Eng.; D. W. Finlay, M.D. Glasg.; A. Newsholme, M.D. Lond.; Louis C. Parkes, M.D. Lond.; H. F. Parsons, M.D. Lond.; C. E. Saunders, M.D. Aberd.; W. R. Smith, M.D. Lond; W. E. Steavenson, M.D. Cantab.; J. F. J. Sykes, M.B., B.Sc. Ed.; E. F. Willoughby, M.B. Lond.; D. S. Davies, M.B. Lond. (Bristol); R. Bruce Low, M.D. Ed. (Helmsley); and J. F. W. Tatham, M.B. Dub. (Salford)—Hon. Secretaries: J. Edwin Cooney, L.R.C.P. Ed. (20, Vereker-road, West Kensington, S.W.); H. A. Fotherby, L.R.C.P. Lond. (St. George's Infirmary, Fulham-road, S.W.)

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BALDWIN, T. A., M.D Dub., L.R.C.S.I., has been appointed Assistant Surgeon to the Hull Royal Infirmary.

BOND, B. M., M.R.C.S., L.R.C.P., has been appointed Resident Clinical Assistant to the East London Hospital for Children and Dispensary for Women, Shadwell.

DE'ATH, GEORGE HANBY, M.R.C.S., L.R.C.P.Lond., has been appointed Coroner for the Winslow Division of Bucks; Medical Officer to the Buckingham Workhouse; Medical Officer for the Leckhampstead District of the Buckingham Union; Medical Officer of Health for Buckingham; and Medical Officer of Health for the Leckhampstead District of the Buckingham Union.

FISHER, H. HOLDRICH, M.B.Lond., M.R.C.S., L.R.C.P.Lond., has been appointed Surgical Assistant to the Glasgow Royal Infirmary.

HOWLETT, E. H., F.R.C.S., has been appointed Assistant Surgeon to the Hull Royal Infirmary.

MURDOCH, ANDREW, M.B., C.M.Glas., has been appointed Medical Officer for the Rainford District of the Prescot Union.

PETCH, RICHARD, M.D.Lond., M.R.C.S., L.S.A.Lond., has been appointed Honorary Medical Officer to the York County Hospital.

PHILLIPS, H. A., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Dunham District of the East Retford Union, for the Newton-on-Trent District of the Gainsborough Union, and for the Clifton District of the Newark Union.

PIGEON, H. W., M.B., B.C., F.R.C.S., has been appointed Assistant Surgeon to the Hull Royal Infirmary.

ROCKLIFFE, W. CRAVEN, M.A., M.B.Cantab., M.R.C.S., &c., has been appointed Honorary Ophthalmic Surgeon to the Hull Royal Infirmary.

SHEPERD, R. J., L.R.C.S.I., L.K.Q.C.P.I., &c., has been appointed Medical Officer for the Rednorshire District of the Hay Union; and Public Vaccinator and Medical Officer of Health for the District, vice Applebe, resigned.

STANILAND, SAMUEL, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Stapleford District of the Wilton Union.

TANNER, HERBER, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Audlem District of the Nantwich Union.

TURNER, RICHARD, M.B., has been appointed Honorary Medical Officer to the York County Hospital.

Births, Marriages, and Deaths.

BIRTHS.

DICKSON.—On the 11th inst., at Great Marlow, Bucks, the wife of John Dunbar Dickson, M.D., of a son.

FENNER.—On the 7th inst., at Cromer, the wife of Robert Fenner, M.R.C.S., L.R.C.P., of a son.

IMLACH.—On the 9th inst., at Canning-street, Liverpool, the wife of Francis Imlach, M.D., of a son.

PEARCE.—On the 14th inst., at Lennox Villa, Hurstp'erpoint, the wife of Henry Pearce, M.R.C.S., L.S.A.Lond., of a son.

WAGSTAFF.—On the 9th ult., at Acre-lane, Brixton, the wife of John Philip Wagstaff, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.Lond., of a daughter.

MARRIAGES.

DAVIDSON—HENDERSON.—On the 6th inst., at St. Augustine's, Forest-hill, by the Rev. J. H. Morgan, D.D., James McKenzie Davidson, M.B., C.M., of Aberdeen, to Georgiana Barbara Watt, daughter of the late W. Henderson, of Aberdeen.

FRASER—WEIR.—On the 7th inst., at the Cottage Moor Farm, Tain, Scotland, by the Rev. Colin MacNaughton, of Tain, Alexander Fraser, Esq., M.B., Professor of Anatomy, Royal College of Surgeons, Dublin, to Joanna Calder, second daughter of the late Rev. James Weir, A.M., Minister of Drainie.

DEATHS.

ALEXANDER.—On the 7th inst., at Margery Hall, Forest-gate, E., Frederick John Alexander, M.R.C.S., in his 63rd year.

BENSON.—On the 6th inst., Patrick Benson, M.R.C.S., L.S.A.Lond., aged 83.

BRAMWELL.—On the 10th inst., at 23, Drumsheugh-gardens, Edinburgh, Effie, youngest daughter of Byrom and Martha Bramwell, in her 11th year.

BROSTER.—On the 10th inst., at Marland-place, Southampton, John Broster, M.D., aged 52.

FOWLER.—On the 8th inst., at Brockett Hall, Torquay, Elizabeth Clara Emily (Lilly), only daughter of Oliver H. and Caroline Fowler, of Cirencester.

LOGIE.—On the 6th inst., at Queensborough-terrace, W. (of heart disease), Cosmo Gordon Logie, Surgeon-General, late of the Royal Horse Guards (Blue).

PICKFORD.—On the 13th inst., William Henry Pickford, formerly Surgeon-Major, Grenadier Guards, and late Surgeon-Major, Scots Guards, in his 52nd year.

RAYNER.—On the 8th inst., at Tiviot Dale, Stockport, William Rayner, M.D.Lond., aged 75.

TATE.—On the 9th inst., at Camden-road, N.W., George Tate, M.R.C.S., L.S.A.Lond., aged 84.

TAYLOR.—On the 4th inst., at Crow Trees, Bradford, Yorkshire, William Taylor, M.D., aged 72.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EUROPEAN CAPITALS AND THEIR WATER-SUPPLY.

ROME heads the list with her 204,000,000 litres of pure water every twenty-four hours. Her population being 345,036, every inhabitant can dispose of 591 litres per diem. London comes next, for every one of whose 4,085,040 inhabitants there are 300 litres daily. Paris takes the third place, her population amounting to 2,240,124, and each inhabitant having for alimentary uses 58 litres per diem, and for secondary purposes 169—a total of 227 litres. Berlin has 1,302,283 inhabitants, for each of whom there are 140 litres daily; Vienna, 770,172 inhabitants, with 100 litres each per day; Naples, 463,172, with 200 litres; and Turin, 278,598, with 98 litres a head every twenty-four hours.

A CURIOUS COINCIDENCE.

To the Editor of THE LANCET.

SIR,—You may think the following rather remarkable coincidence worth recording. Soon after it was published I recently purchased a work on Medicine in the Borough. About a fortnight or so ago I found that an error had been made in binding it—viz., pages 817-32 left out and pages 833-48 inserted in duplicate. The publishers very promptly undertook to rectify the mistake on my notifying it to them. They returned it on April 1st. On April 8th I purchased of the same bookseller a copy of another work, and on inspecting my purchase later on I discovered that an exactly similar error had been made in binding it—viz., pp. 65-80 left out and pp. 81-96 inserted in duplicate. Considering the number of books issued daily, the small percentage of mistakes that occur in binding them, and the variety of mistakes that might be made, it certainly is strange that two books similarly imperfect should have been issued by the same publishers, pass through the same booksellers, and finally reach the same purchaser—the one exactly a week after the corrected copy of the other had been returned. Perhaps some mathematician would like to calculate the chances against such a coincidence occurring again before the end of this century!—or next!

I am, Sir, yours truly,

April 12th, 1886. C. L.

DON JUAN CUESTA Y CKERNER.

THE death of Dr. Tejada, editor of the *Genio Médico Quirurgico*, which we noticed a short time ago, has been followed by that of another representative of the Madrid medical press—viz., the venerable and much esteemed editor of the *Correspondencia Médica*, Señor Don Juan Cuesta y Ckerner. One of the last paragraphs he penned was for the issue of March 16th, on the death of his friend and rival, Dr. Tejada, in which he stated his regret that, owing to infirmity from which he had long suffered, causing dyspnœa, he was unable to be present at the funeral, adding, almost prophetically: "How often I have thought during the attacks of asphyxia which seize me that he and I would be travelling the path of eternity together."

ROYAL COLLEGE OF SURGEONS.

THE following are the questions put to the candidates at the late examination in Anatomy and Physiology:—

Anatomy.—From 2 to 5 o'clock P.M. Candidates to answer at least four questions.

1. Mention the muscles which are attached to the following parts of the skeleton—(*a*) Great wing of the sphenoid, (*b*) angle of the inferior maxilla, (*c*) coracoid process of scapula, (*d*) coronoid process of ulna, (*e*) internal cuneiform bone of the foot. Give the nerve-supply of each muscle.

2. Describe the dissection necessary to expose the common femoral artery.

3. Describe the under-surface of the liver, and state the relative position of structures in contact with that surface.

4. Give the origin, course, and distribution of the spinal accessory nerve.

5. Describe the innominate artery, and give its course and relations.

6. Describe the arrangement of the superficial veins of the upper extremity.

Physiology.—From 2 to 5 o'clock P.M. Candidates to answer at least four questions.

1. Describe the circulation of the blood through the liver. Give the structure and functions of a hepatic lobule.

2. Describe the structure of a bronchial tube. Mention the uses of each of its constituents.

3. Explain the processes by which the normal temperature of the body is maintained and regulated.

4. Give the microscopic structure of a striated muscle-fibre. How may a muscle be excited to contract? What phenomena accompany contraction?

5. Describe the development and structure of a ripe Graafian follicle. What change does it undergo after the discharge of the ovum?

6. What is the meaning of the term "blood-pressure"? By what circumstances may blood-pressure be modified?

CASE OF STRANGULATED HERNIA.

To the Editor of THE LANCET.

SIR,—The following particulars of a case of strangulated hernia may be of interest to some of your readers.

On the evening of Sept. 2nd, A. B——, fireman, came to my surgery, stating that he had fallen on a joist while cleaning the engine-room skylights, and saying "he thought he had ruptured himself." He fell at 4 P.M., and at the time did not experience any uncomfortable feelings. A short time afterwards he found a small tumour, which very quickly got larger as he continued working. I examined him, and found his scrotum an enormous size. I immediately placed him on the surgery floor and endeavoured to reduce the tumour by taxis. Having failed, I got the chief engineer to administer chloroform, under my superintendence, and again tried to reduce the swelling. For three-quarters of an hour I steadily laboured at the case, and, giving up all hope, I determined to operate. Having placed the patient on a suitable bed in one of our hospitals, I operated at 7.15, having up to then tried every effort at reduction. I was assisted by Mr. Kennedy (engineer), who gave chloroform (the chief engineer being tired) and Mr. Helberg (purser), who gave me most valuable assistance throughout. In operating, when I came to the sac I found it much congested, being caused, as I thought, by the efforts previously made at reduction. I divided the constriction, and returned the tumour with slight difficulty. Having tied the few vessels, I waited to see if any more were bleeding, but finding none, I brought the edges of the wound together, applying some carbolised oil, a pad, and spica bandage. After the operation he was quite cheerful. In an hour and a half I saw him again, when he said "the tumour was coming down." I immediately undid the bandage, and found a tumour at the site of the wound, also the scrotal bag enlarged. I cut the sutures, removed some clots of blood (for of such the tumour was composed), and, having discovered two small vessels bleeding, I tied them, and once more brought the edges of the wound together. I then applied some pounded ice in a napkin to the wound, the application of ice being carefully repeated throughout the night. At 11 o'clock I gave him half a drachm of tincture of opium. In the morning he felt very well. Pulse and temperature normal. We then arrived at Adelaide, and the Government inspecting medical officer, Dr. Toll, came on board. He kindly took the case into hospital, while we proceeded on our way to Melbourne. While in hospital the case was as follows:—The first night there was an elevation of two degrees in temperature, which went down again next morning. The bandages were undone, and the wound on examination looked healthy. It was dressed with carbolic lotion (1 in 40), and improved daily, healing by granulation. The bowels, which up to this had not been moved, were relieved on the seventh day. The patient was able to go about in twenty days after the operation. He is now on board, and is quite well. I have advised him to discontinue his work as a fireman, for I consider labour in the stoke-hole unfit for a man in his condition.

I am, Sir, yours very faithfully,

P. H. ROCHFORT,

March, 1886. Physician and Surgeon, Royal Mail *s.s. Soracta*.

A HEALTHY CITY.

SPEAKING of Goulburn, in New South Wales, a recent English visitor, Dr. J. E. Taylor, says: "It is a picturesque and clean town, with wide streets and fine buildings, surrounded by a breezy, open country on one side, and a bold, craggy ridge, half forest-clad on the other." He then proceeds to state that "Goulburn is said to be so healthy that the doctors rely on the natural increase of population for a living! People are neither in a hurry to be sick nor to die."

Mr. W. Rayner.—There is high legal authority for the statement that workhouse *infirmaries* are not included under the term "hospitals" in relation to the Coroner's Inquiry Act. But although we believe that technically a medical man could claim fees for giving evidence as to the cause of death taking place in workhouse infirmaries, long usage to the contrary has become an "unwritten law."

Mr. T. E. Young.—Any saccharine substance will answer the purpose.

CONGENITAL NÆVOID LIPOMA.

To the Editor of THE LANCET.

SIR,—I have thought that the notes of the following case might prove of interest to some of your readers.

J. B——, aged eight weeks, is anæmic, emaciated, and has snuffles. No other specific history or symptoms. In the left axilla there is a nævoid growth, somewhat larger than a walnut in size, and over the spine of the left scapula two nævus stains. The veins of the arm on the same side are dilated and tortuous, without heat, pain, thrill, or pulsation of any kind. The skin and subcutaneous tissue between the shoulder and elbow are pendent, flabby, and pervaded by an indolent and incompressible growth, apparently consisting of large meshes of connective tissue containing numerous fat-cells, and being traversed by thickened and dilated vessels, constituting a distinctly vascular element. The subcutaneous tissue is adherent to the skin. In the forearm there are two swellings, one about the size of a pea, the other rather more than twice that size, produced partly by a tortuosity of the vessels and partly by fibro-fatty growth. The terminal phalanges of the left hand are double-jointed, the middle finger deviating considerably towards the ulnar side. The ends of the fingers occasionally become cyanosed. Over the manubrium sterni on the left side is an enlarged lymphatic gland. The right shoulder and arm present no nævoid appearance or discolouration; nevertheless, the integuments on this side from the elbow to the shoulder are pendent and soft, being involved by a fibro-fatty growth, identical with that existing on the opposite side. The growth at present causes no pain or inconvenience to the child, nor does it much impede the movements of the arms. The mother says that the growth still increases.

I do not consider this a case for operative interference at present, since, as stated above, it does not now cause any distress or material inconvenience, and, moreover, since former cases prove that these growths have a strong tendency to recurrence. Again, the anatomical relations to the growth in the axillary region would in most minds preclude the idea of any operative interference. It is when these growths are situated in the anterior part of the thigh, just below Poupart's ligament, close upon and almost in relation with the femoral vessels, that they cause most inconvenience by the pressure which they exert on the femoral vein, producing œdema of the limb, and necessitating some surgical interference. The mother states that during the time she was carrying the child, and just prior to the period of quickening, she had a fright. As she was passing along the street one day a monkey suddenly sprang from a window on to her shoulder, and tore off her shawl. She considers that this incident may perhaps account for this strange anomaly.

I am, Sir, yours obediently,
Hounslow, March 3rd, 1886. C. GOWER LEMMITTE, M.R.C.S., &c.

SALICIN.

THE willow is now being largely cultivated in America for medicinal purposes. The switches at the end of two years are from four to seven feet long, and are cut and gathered into bunches like sheaves of wheat. In the stripping building they are steeped in water, and the bark at the larger end is loosened for a couple of inches by machinery. One by one the switches are placed in the mechanical stripper, and with a pair of pliers are pulled through with a sudden jerk. They are then wiped off with a woollen cloth, bundled, and laid away to dry. All the leaves and bark are dried and baled, when they command a price of twenty-five cents a pound. On one farm in Georgia there are at present 400,000 willows growing, and 80,000 additional slips have recently been put in, it being intended eventually to devote sixty acres to this crop. The average yield is a ton to the acre. When dried, the willows command 200 dollars per ton, and find a ready market.

"DOCKED FEES."

To the Editor of THE LANCET.

SIR,—The question of guinea *versus* sovereign may be considered as finally settled. In a question of fees submitted to the arbitration of the highest authorities not very long ago their award was expressed in pounds. From this it must be inferred that, as regards the medical profession, the guinea is now abandoned. None of the classes alluded to by "M.B. Dub." are the least likely to follow our example, and so we shall be still more victimised. I am, Sir, your obedient servant,

April 9th, 1886. M.D.

ACORN-COCOA AS FOOD IN CHILDREN'S DISEASES.

DR. GUSTAV V. HÖSSLIN writes in the *Münchener Medicinische Wochenschrift* that he has tried a food called "acorn-cocoa" (eichelcacao), which had been used in Prof. Senator's polyclinic and the Augusta Hospital in Berlin, and has found it as valuable as it had been reported to be. It is composed of cocoa, baked acorns, sugar, and baked flour. He employed it in the cases of thirty children, varying in age from four weeks to six years, suffering from chronic diseases of various kinds, in twenty-nine of whom it produced an immediate and permanent improvement. The youngest children were given no other nourishment, beyond some milk, with it, the elder ones only having soup in addition. The little patients liked the food, and their appetites soon began to increase. Dr. v. Hösslin has also tried the acorn-cocoa in phthisis in the case of adults, and thinks that it has been of benefit, but suggests that further observations are required on this head.

PECULIAR FORM OF WHOOPING-COUGH.

To the Editor of THE LANCET.

SIR,—I should feel obliged if any of your readers would state whether they are acquainted with the following peculiar form of whooping-cough occurring in an elderly man, a little over fifty years of age. It commenced with an irritating laryngeal cough, attended with slight expectoration. But in about three weeks from the commencement, on the termination of each paroxysm of coughing, the patient was seized with a violent attack of suffocation, caused apparently by spasmodic closure of the glottis, and lasting from thirty to sixty seconds. These attacks caused very great distress, especially during the night; but a cough-mixture containing hydrochlorate of morphia was of great benefit, and prevented the patient from being utterly exhausted by want of sleep.

Two weeks later—that is to say, five weeks from the commencement of the cough, several characteristic "whoops" occurred during the attacks of coughing, while the spasms of suffocation after each attack continued as before. It was then decided to treat the affection as whooping-cough, with full doses of the tincture of belladonna, while the morphia was entirely stopped. Almost immediately the spasms of the glottis seemed to be subdued by the belladonna, and after three days they almost entirely ceased. The patient now continues to suffer from the characteristic "whoop"; but the cough has greatly decreased in frequency and severity, and the spasms of the glottis have disappeared. If, however, the belladonna were to be entirely discontinued, there is reason to fear that the spasms would return. The patient had whooping-cough in his childhood, but only very slightly.

The peculiarity of the case consists in the occurrence of the spasms of the glottis so long before any distinct symptoms of whooping-cough had appeared. The inhalation of chloroform during each spasm gave very decided relief. I am, Sir, yours faithfully,

Naval and Military Club, Piccadilly, W., April 14th, 1886. M.D.

FOOD FOR THE POOR: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—Since the end of the Russo-Turkish war I have not had the need to write to you, but lately I have felt I might offer you a few observations. In the first place, with regard to food for the poor and unemployed in London. I have seen no mention of a trial having been made of Indian corn meal—the "polenta" of Italy, the "mamaliga" of Roumania,—and yet, I assure you, it is excellent. In Roumania we have no starving population, but the peasants content themselves with mamaliga, which is prepared by Indian meal being stirred into boiling water until it becomes a very thick batter; it is then poured out on to a wooden platter, when it becomes solid. It is eaten hot, alone or with an onion, or a dried fish, or "tourt" (thick sour milk), or with a slice of goat's milk cheese. It is rarely that our peasants taste bread, and yet they are as a rule strong and healthy. Mamaliga is served very often at the table of the rich, but then the meal is sifted before boiling, and it has the addition of fresh butter. As an experienced housekeeper, I think in English kitchens, where they complain of insufficient cooking accommodation, it would be a welcome innovation were they to serve occasionally a lump of hot mamaliga and a morsel of cheese rather than the eternal soup. I am, Sir, yours faithfully,

Caimata, Bucharest, Roumania, April 2nd, 1886. EMMA B. MAWR.

THE TREATMENT OF GONORRHŒA CHRONICA BY INJECTIONS.

To the Editor of THE LANCET.

SIR,—There can be no question, as Dr. Casper says, ordinary injections in gonorrhœa chronica do not reach the real seat of the mischief; but if they are applied by means of Brichsen's liquid caustic catheter, quite as rapid an effect is produced as with Dr. Casper's grooved bougies. Three or four drops only are injected by this means; but this quantity is quite sufficient for the purpose, and the operation rarely requires repeating more than three or four times at the most, and then only at intervals of from five to seven days. The inflamed spot is easily detected by the pain the catheter produces on reaching it.—Your obedient servant,

Surbiton, Feb. 19th, 1886. F. P. ATHINSON.

ERRATUM.—In the seventh line from the bottom of our notice last week of Dr. Spencer's binaural stethoscope, for "consultation" read auscultation.

Medical Diary for the ensuing Week.

Monday, April 19.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. John Morgan: Notes of a case of Littré's Hernia.—Dr. Day: Two cases of Simple Meningitis in Children, their Difficulties in Diagnosis.

Tuesday, April 20.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Lockwood: (1) Congenital Fatty Tumour from Sole of Foot; (2) (for Mr. W. Adams) Fatty Tumours from Palm of Hand; (3) Abnormality of Colon.—Dr. Sharkey: Meningeal Hæmorrhage.—Mr. E. H. Fenwick: Stone impacted in Prostatic Urethra.—Mr. Arbuthnot Lane: The Pathology of Rheumatoid Arthritis.—Mr. R. Williams: Colloid Cancer of a Uterine Fibro-myoma.—Dr. Charlewood Turner: Specimens of Pulmonary Thrombosis.—Mr. R. W. Parker: Obliterative Tracheitis and Bronchitis in Congenital Syphilis.—Dr. Dalton: Tumour of the Ventricle from a case of Diabetes.—Mr. Mansell-Moullin: Primary Sarcoma of Spermatic Cord (card).—Dr. Silcock: Glandular Epithelioma from the Lung of a Dog (card).

Wednesday, April 21.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 8 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Thursday, April 22.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, April 23.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, April 24.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
To CHINA AND INDIA	One Year		1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES	Ditto		1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Croonian Lectures
ON
SOME POINTS IN THE PATHOLOGY OF RHEUMATISM, GOUT, AND DIABETES.

Delivered at the Royal College of Physicians of London, April, 1886.

By P. W. LATHAM, M.A., M.D., F.R.C.P.,
DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—The metabolic function of the liver may be interfered with in diverse ways. From the stimulating effect of food during digestion in the stomach or duodenum two things should take place in the liver—dilatation of the vessels of the gland and certain changes in the gland cells; results which may be compared to those obtained from the submaxillary gland by stimulating the chorda tympani, the metabolic events being dependent upon the absorption and transformation of certain constituents of the blood by the hepatic cells, and this action controlled by the nerve fibres in connexion with these cells. But these two processes, vascular dilatation and metabolic activity, are independent of each other. The vessels may dilate, but if the terminal portions of the nerves of the secreting cells are paralysed, the blood will pass through the gland more or less unchanged; and the same effect will be produced by paralysing the nerve either at its central origin or along its course. We know that, as regards the innervation of the tongue and the sense of taste, there are nerve filaments which respond only to particular kinds of stimuli; so it is not unreasonable to assume that, distributed to the liver cells, there are various nerve filaments, one set regulating the transformation of saccharine, the other the nitrogenous elements conveyed to the cells by the portal circulation; and if either set be paralysed, we should have the metabolism of the corresponding elements interfered with. How far the secretory power of the liver cells is influenced by the vagus is not very clear; but the vessels are under the control of the dominant vaso-motor centre, which is located in the medulla oblongata, where also we have the nucleus of the vagus. If, then, there is a want of harmony between the vascular dilatation and the action of the liver cells—if blood containing the products of digestion is passing through the liver in larger quantity than the cells can act upon (whether that inaction be due to exhaustion of the cells themselves or to exhaustion of the secretory nerves in connexion with them), then there will be imperfect metabolism, and consequently the formation of uric acid in the manner I have described. So far as the imperfect metabolism of the saccharine elements is concerned, we have illustrations of what I mean in the results which take place from the "diabetic puncture," or, as shown by Dr. Pavy, from section of the sympathetic filaments ascending from the superior thoracic ganglion, or from the removal of the superior cervical ganglion.

There may be also imperfect metabolism of nitrogenous material, in another way—viz., if too much is introduced into the portal vein from the alimentary canal. The portion then which is least readily acted upon (viz., the glycocine) will not be transformed, and so the formation of uric acid is promoted. We see the same thing constantly even when the liver is in a healthy and normal condition, if it has too much work imposed upon it—that is, if more nitrogenous material is introduced into the portal vein than can be transformed in the gland. And so an occasional indulgence at the table is very generally succeeded by the appearance of urates in the urine. If the liver cells are already exhausted by long-continued over-stimulation, with how much greater difficulty will the perfect metabolism of nitrogenous food be effected!

In either of these modes, then, arising from defective changes in the liver, uric acid may be formed in excess, and then eliminated, or circulate as a poison in the blood. Why in some cases is it eliminated as urates or as uric acid in the urine or as renal or vesical calculi, without any arthritic symptoms? Why in others does it develop the arthritic symptoms to which we give the name of gout?

If the kidneys are sound, as in the majority of people below middle age, the uric acid, unless in large excess, will be excreted directly it is formed, and there is little overflow of the product into the circulation; if the urine has a neutral reaction, it will appear as urates of ammonia, soda, &c.; if, however, other acids, such as lactic acid, are formed at the same time and eliminated by the kidneys, the base will be separated, and uric acid, as such, excreted, and, according to the amount, will give rise to gravel or renal or vesical calculi. But gradually the kidneys may become weakened or diseased, and then, as the blood passes through them, the acid is formed, and a portion passes on and is not eliminated. Being an abnormal product, we are making no violent assumption in saying that it will act as an irritant upon some portion of the nervous system. We have seen how distinctly the similar body caffein acts as a stimulant to certain portions of the nervous system. According, therefore, to the susceptibility or sensitiveness of different portions will be the outward manifestations of this irritation. Such a susceptibility or sensitiveness of the nervous system is constantly observed in different individuals. In some the nerve of smell is much more easily stimulated by certain odours than in others. In some, again, the nerves of taste recognise differences in flavour which are totally imperceptible to others. In children, too, and in persons in enfeebled health, how readily is pyrexia developed by irritation of the nerves of the intestine or the digestive glands from improper diet!

If the nucleus of the vagus is the sensitive spot, then gastric uneasiness, asthma, or cardiac irregularities might be developed.

Dr. Buzzard has suggested that in locomotor ataxia "the frequency of the coincidence of gastric crises with the osseous lesions gives reasonable ground for the hypothesis that the latter may depend upon an invasion of a part of the medulla oblongata closely adjacent to the roots of the vagi. It is only as a working hypothesis that I make the suggestion. Is there something which we may call provisionally a trophic centre for the osseous and articulatory system in the immediate neighbourhood of the roots of the vagi? As I have suggested on a previous occasion, the discovery of such a centre would materially help us to explain the remarkable association of cardiac complications with the joint-affection of acute rheumatism, as well as the sweating characteristic of this disease, and the occasional hyperpyrexia which occurs in it. And it might also help to throw light upon the obscure pathology of arthritis deformans."[1] In a subsequent paper he further adds: "In a communication brought before the Pathological Society of London, in February, 1880 (Transactions of the Pathological Society, 1880), I made the suggestion that the gastric crises depend upon irritation of the nuclei of the vagus by sclerosis. At that time I had no anatomical evidence to offer in support of the hypothesis, which was based upon the paroxysmal character of the attacks, so completely in accord with that characterising the attacks of lightning pains. It appeared evident to me that if sclerosis, which, when it attacked nerves of common sensation, produced pain, came to invade the nucleus of the vagus, it might be expected to give rise to symptoms like those of the gastric crises. During the meeting of the International Medical Congress in London, Professor Pierret, of Lyons, has shown me sections of the medulla oblongata which he has lately made from a case of tabes with gastric crises. I was greatly interested in his demonstration that the fasciculus gracilis in immediate relation with the nuclei of the vagus exhibited distinct sclerosis."[2]

Professor Roy and Dr. Graham Brown have recently stated[3] that "in the curarised dog stimulation of one uncut vagus with an induced current causes contraction of the bronchi of both lungs, the contraction being usually powerful, but to this there are exceptions. Section of one vagus usually causes a marked expansion of the bronchi of the correspond-

ing lung, which may be preceded by a slight temporary contraction, apparently due to the stimulus of the section. Stimulation of the peripheral end of one cut vagus always causes a much more powerful contraction of the bronchi of both lungs than when the uncut nerve is stimulated with the same strength of induced current," and that these and other experiments enable them to understand how asthma may be produced.

If portions of the spinal cord, in connexion with the nerves distributed to the joints are more than usually sensitive, this sensitiveness or susceptibility being either inherited or acquired, then stimulation or irritation of these portions would lead to changes in the respective joints similar to those which result from nerve wounds or from injuries to the spine. At first the uric acid might produce little effect, but with repeated or constant stimulation, these portions of the spinal cord would become more susceptible to the action of the morbid product, and so nutritive changes or inflammation would be developed in the joints connected therewith. Suppose for a moment that the portion of the nervous system most susceptible to the action of the uric acid is the vaso-motor centre, the dominating portion of which, as we know, is located in the medulla oblongata, what effects should we expect to follow? The most powerful vaso-motor nerves are those which act upon the bloodvessels of peripheral parts—e.g., the toes, fingers, and ears,—while those that act upon central parts seem to be less active;[4] consequently we should expect the toes and fingers to be first affected, and just as by stimulating the sympathetic nerve of the sublingual gland we have contraction of the vessels and altered secretion from the gland, so in the toes and fingers we should have contraction of the vessels and the metabolism of the parts more or less modified. In addition to contraction of the vessels caused by impulses affecting the blood-supply, there are impulses affecting directly the activity of the protoplasm. The constructive metabolism about the joints is stimulated, whilst the blood-supply and destructive metabolism are lessened, and so there is increased development or growth about the part. Further, the blood which goes to the part contains sodium urate; consequently this is deposited, along with the other substances, in the metabolism or inflammatory changes which take place in the tissues around the affected part.

But whilst the vaso-motor centres may be directly stimulated by the irritant, they may be also stimulated by irritation of the efferent or sensory nerves. Stimulation of the centripetal end of a divided efferent nerve causes increased blood-pressure. Have we not here, then, an explanation of the phenomena of a gouty paroxysm? The uric acid stimulating both the sensory nerve, and through it or independently the more active portion of the vaso-motor centre, causes pain in the joint and contraction of the vessels; the pain increases with the continued stimulation, but after a time the nerve is exhausted or paralysed, as we know is the case from continued stimulation of other nerves—as, for instance, in tetanising a muscle. The vessels now dilate, destructive metabolism is stimulated, there is relief from pain, and with the relief another indication of paralysis of the sympathetic shows itself—viz., more or less perspiration. A similar explanation may, I think, be given of the mode in which arthritic symptoms result sometimes from nerve wounds. The wound may be such that the sensory or efferent fibres in the nerve are injured, whilst the vaso-motor and other fibres are intact. From the irritation set up either by the cicatrix or otherwise, the sensory fibres, and through them the vaso-motor centres, are stimulated in the manner I have just described as occurring in gout, but as uric acid is not the irritant and is not circulating in excess in the blood, there is no deposit of this substance in the metabolic changes taking place in the joint. And, further, if irritative inflammatory or degenerative changes take place in the spinal cord anywhere along the course of the sensory nerves, by which the sensory nerves are stimulated, this would lead to stimulation of the corresponding portion of the vaso-motor centres, and so to the development of those symptoms which we know under the name of arthritis deformans, or rheumatoid arthritis. In this way we can easily understand how dysmenorrhœa may be the starting-point of this joint affection—a clinical fact which has been recorded by Dr. Ord.

Among the peculiar local affections in connexion with gout, we have, as pointed out by Dr. Graves, congestion of the lobes of the ear; a singular affection of the teeth, which consists in an insuperable desire to grind them; the occurrence of tic douloureux of several branches of the fifth pair; and daily paroxysms of intense heat of the nose, which continues for three or four hours, the part becoming first of a bright and then of a purplish-red colour. All these symptoms may, I think, be ascribed to irritation in that portion of the nervous system where the roots of the fifth nerve and the vaso-motor centre are in close proximity—namely, in the medulla oblongata. To this spot I shall have to refer again.

But independently of any functional or organic change in the liver or its nervous connexions, there is a third way in which uric acid may be developed, and that is from the excessive formation of glycocine in the muscular tissue, in the manner I have already referred to as the result of what is commonly called a feverish cold. This glycocine, passing in the blood to some glandular organ—the liver or spleen it may be,—is there conjugated into hydantoin, and afterwards further transformed into uric acid. If the nervous system and the kidneys are sound, this product is eliminated by the kidneys, and the attack subsides. But suppose the individual who is exposed to damp or cold has been previously reduced in strength, is tired out or exhausted—that is to say, his vaso-motor system or some portion of it is in a weak state, the weakness either developed from bodily or mental exhaustion, or, it may be, inherited. Then following the chill there would be the same effects produced as I have described when referring to the effect of cold applied to the skin, but the vaso-motor centre being enfeebled, the nerves regulating the vessels of the muscular area would be more completely paralysed by the external cold, and when reaction, induced in some degree by the lactic acid, sets in on the surface of the skin, there would be less power in the muscular nerves to recover from that paralysed condition; and more than this, so far as these vaso-motor elements are concerned, the morbid products are still circulating in the system, and the vaso-motor centre not having recovered itself, the continued stimulation by glycocine or uric acid on that exhausted centre no longer excites it, but gives rise to further exhaustion, and consequent further dilatation of the vessels in the vascular area connected with it, and more complete falling asunder of the molecular elements of the tissue.

Let me illustrate what I mean by reference to the sciatic nerve.

"Division of the sciatic nerve of a mammal causes dilatation of the small arteries of the foot and leg. Where the condition of the circulation can be readily examined—as, for instance, in the hairless balls of the toes, especially when these are not pigmented—the vessels are to be seen dilated and injected; and a thermometer placed between the toes shows a rise of temperature amounting, it may be, to several degrees."[5] "But the dilatation so caused after a few days disappears; the foot on the side on which the nerve was divided becomes not only as cool and pale, but frequently cooler and paler than the foot on the sound side. If the peripheral portion of the divided nerve be stimulated with an interrupted current immediately or very shortly after division, the dilatation due to the division gives place to constriction: the sciatic nerve acts then quite like the cervical sympathetic, except, perhaps, that this artificial constriction cannot be maintained for so long a time, and is very apt to be followed by increased dilatation. If, however, the stimulation be deferred for some days, until the dilatation has given place to a returning constriction, the effect is not constriction but dilatation; the nerve then acts, so far as its vaso-motor fibres are concerned, like a muscular nerve, and not like the cervical sympathetic."[6] So also with regard to the mylo-hyoid muscle. Section of the nerve produces dilatation, but the dilatation is transient. The vessels speedily return to their former calibre, and then it is found that stimulation, of whatever strength, of the peripheral portion of the divided nerve brings about, not constriction, but dilatation. If, then, the vaso-motor fibres of the muscular nerves have been weakened, the result would be that the normal stimulating effect of uric acid on the vaso-motor elements connected with motor nerves generally would be transformed into a depressing or paralysing effect; the vessels of the muscular area would be still further dilated; the molecular constituents of the tissue would be loosened; hydration and oxidation would go on causing fresh development of heat; there would

[4] Landois and Stirling: Physiology, 1885, p. 893.

[5] Foster's Physiology, fourth edition, p. 199. [6] Ibid., p. 209.

Digitized by Google

be the continuous formation of glycocine and lactic acid, the glycocine giving rise to uric acid, which accumulating in the system, produces its deleterious effect in modifying the function of the nervous system; the lactic acid dilating the smaller arteries[7] and stimulating the sweat centres, passing off in part by the skin. With increased stimulation of the paralysed centre of the muscular nerves complete dilatation of the vessels in the muscular area will take place; the molecular constituents of the tissue now fall completely asunder, the $CH_2\begin{cases}OH\\CN\end{cases}$ and $C_2H_4\begin{cases}OH\\CN\end{cases}$ being entirely hydrated into glycollic acid and lactic acid with the rapid production of heat, and the heat is further developed by the ready oxidation of these products. In this way to some extent the so-called hyper-pyrexia of rheumatic fever is produced.

But whilst uric acid affects in this way the vaso-motor fibres of muscular nerves, it also affects the nutrition of the joints. I have endeavoured to explain how it does so in gout, producing first of all contraction of the arteries and constructive metabolism by the stimulating effect of the poison on the sensitive nerve centres, followed by dilatation of the arteries and destructive metabolism when the centres are exhausted. In rheumatism, however, the dominant centre is exhausted to begin with, and so we have destructive metabolism and vascular dilatation, preceded by very slight, if any, constructive metabolism and contraction of the vessels. In gout the uric acid is the result of modified innervation of the liver or exhaustion of the hepatic cells, and so there is non-transformation of the glycocine and the consequent formation of uric acid. In rheumatism the glycocine results from changes in the vascular area and in the metabolism of the muscles, and along with its formation there is also the formation of lactic acid by hydration, both from the cyanalcohol $CH_2 \cdot CH_2\begin{cases}OH\\CN\end{cases}$ and the cyanalcohol $CH_3 \cdot CH\begin{cases}OH\\CN\end{cases}$; the nutrition of the joint is modified, as above described, by the uric acid, but the nutrition is further modified by the presence of the lactic acid in the blood, producing dilatation of the arterioles, more particularly of those in the cutaneous area. In this manner, then, I venture to suggest, are the characteristic changes about the joints in acute rheumatism developed.

Again, if the dominant vaso-motor centre is in an enfeebled or exhausted state, and irritative, inflammatory, or other changes take place in the spinal cord along the course of or adjacent to the sensory nerves, by which these nerves are stimulated, we should have, quite independently of the presence of uric acid in the blood, destructive metabolism and vascular dilatation about the joints, the extreme effects of which are seen in Charcot's disease accompanying locomotor ataxia. Regarded in this light, Charcot's disease bears the same relationship to arthritis deformans that rheumatism does to gout.

In a similar way, also, I would explain the joint affection known as gonorrhœal rheumatism. Here we have prolonged irritation of the sensory nerves of the urethra, acting through an enfeebled or weakened vaso-motor centre, and in this way the nutrition of the joints in connexion with that centre is modified.

I have referred to that portion of the sensory tract in the medulla oblongata in the neighbourhood of the nucleus of the vagus, the root of the fifth nerve, and the dominant vaso-motor centre, as the part which controls the nutrition of the joints, and which is more particularly affected by external cold. The following facts give support to this view and can be explained on the same hypothesis.

Cases occur in which the solitary local affection associated with a feverish cold is an outbreak of herpes on the lips, nose, or buccal mucous membrane, the so-called "febris herpetica." "We find a sharp attack of fever in a child or young person without any local cause; we expect the onset of some serious disease, but our anxiety is soon allayed: in a few days there unexpectedly appears on the lips, nose, or cheeks, a closely-packed group of vesicles, which at once removes our uncertainty and shows us that we have to do, not with the early stage of one of the more serious fevers, but with a feverish cold which will end favourably in a day or two."[8] Here we have, as the result of "catching cold," disorder of nutrition showing itself in parts supplied by branches of the fifth nerve—viz., the labial and nasal branches of the superior maxillary nerve.

Rheumatism not infrequently after a short interval follows tonsillitis. Attention was prominently called to this a few years ago by Dr. Kingston Fowler, and I have seen several instances where it has occurred. Now we may assume either that the condition of the central nervous system in the individuals so affected is such that slight injurious influences, such as the effect of a slight chill or exposure to cold acting upon the central nervous system, will produce an attack of quinsy, whereas more severe injurious influences will cause rheumatic fever; or we may assume that in quinsy the continued irritation of the sensory nerves distributed to the tonsils produces exhaustion of some portion of the dominant vaso-motor centre, and as in quinsy uric acid is largely developed, this acting on the enfeebled centre exhausts it still more and develops the arthritic symptoms of rheumatism in the manner I have described. Either hypothesis will illustrate my argument. The tonsillar nerves are derived from the fifth nerve—the middle descending branch from Meckel's ganglion—and from the glosso-pharyngeal portion of the eighth nerve. This branch of the fifth, to which I have referred, is derived from the larger root of the nerve, which may be traced back to the lateral tract of the medulla oblongata immediately behind the olivary body, and is connected with the grey nucleus at the back part of the medulla, between the fasciculi teretes and the restiform columns. The deep origin of the glosso-pharyngeal may be traced through the fasciculi of the lateral tract to a nucleus of grey matter at the lower part of the floor of the fourth ventricle, external to the fasciculi teretes. Both these nerves receive filaments from the superior cervical ganglion of the sympathetic.

The occurrence of arthritis in the course of hemiplegia, a point to which I referred in my second lecture,[9] would at first sight appear antagonistic to the theory which ascribed the joint symptoms to neurotic changes in the medulla oblongata. But it only requires a little reflection to show that it gives the strongest support to the theory. Following apoplexy there is descending sclerosis of the lateral columns, which proceeds slowly. When it shows itself in the medulla, irritation may be set up around the degenerating portion, and this, extending to the grey matter and anterior cornua, may set up the arthritic symptoms, which sometimes show themselves in from fifteen days to a month after the apoplectic seizure.

As regards megrim, Dr. Edward Liveing[10] writes: "There can be no question, then, I think, as to the frequent connexion of megrim, whether in its blind, sick, or simply hemicranial forms, with a gouty diathesis and its occasional replacement by fits of regular gout." Some years ago I endeavoured to prove[11] that megrim was due to vaso-motor disturbance—to uncontrolled action, or as I should now say to stimulation of certain branches running from the superior cervical ganglion of the sympathetic followed by exhaustion. Dr. Haig in a recent number of the *Practitioner*[12] asks the question: "May not excess of uric acid in the blood cause such vaso-motor irritation?" Certainly, and in persons who are subject to megrim, whose sympathetic ganglia have this sensitive constitution, the causes which will lead to the formation of uric acid in the system will with tolerable certainty develop an attack of this particular disorder.

Again, with regard to chorea. If the vaso-motor fibres proceeding from the upper cervical ganglion to form the carotid plexus have through prolonged stimulation become exhausted or weakened, there would be, as the result of that exhaustion, vascular dilatation and perivascular change in the track of the middle cerebral artery. But there would also be nutritive changes in the nerve cells of the brain and exhaustion of their metabolic powers. We should, in fact, have a similar condition produced to that of the submaxillary gland when the chorda tympani is stimulated after the injection of atropine, and, *as far as the nerve cells are concerned*, the same result would be produced as ensues from embolism. Their coördinating action would be paralysed in both cases, and such changes would produce the incoördinated movements of chorea. Nor is it difficult to

suppose that sudden shock would give rise both to vaso-motor paralysis and to inhibition of the assimilating power of the nerve cells. Dr. Dickinson has made out very clearly that it is in the tract of the middle cerebral artery and in the posterior and lateral parts of the grey matter and in the upper portions of the cord that vascular dilatation and perivascular change take place both in chorea and diabetes, and I venture to suggest that they are induced in the manner I have indicated.

Will the theory I have here advanced offer any explanation of the shifting character of the rheumatic affection? My application of the theory is as follows: Vaso-motor centres are distributed throughout the whole spinal axis. "They can be excited reflexly, but they are also controlled by the dominating centre in the medulla oblongata."[13] "Now this *general* vaso-motor centre in the medulla oblongata is really a *complex composite centre* consisting of a *number* of closely aggregated centres, each of which presides over a particular vascular area."[14] Some of the nerve cells or some portions of this dominating centre may be more readily exhausted by the continued stimulation of an irritant circulating in the blood than the others, and after the development of the irritant (uric acid) in the system it will of course produce exhaustion first in these particular cells and in the subsidiary ganglia in connexion with them, and so lead to dilatation in the vascular area directly under their control. The other cells in the dominating centre and the subsidiary ganglia in connexion with them, possessing a healthy tone, will be stimulated to action in the normal manner and contraction will take place in the vascular areas connected with them. This action itself would have the effect of driving more blood to the paralysed vascular area and intensifying the symptoms there. But with continued stimulation of these healthy centres, exhaustion will sooner or later be induced; further stimulation increases the exhaustion, and then dilatation of the vessels under their control will be induced; with this dilatation in a new area, the amount of blood in the parts primarily affected will be lessened, and simultaneously will the symptoms which were associated with this increased blood-supply be modified or lessened.

If at any time a joint has suffered injury in any way, this joint will be more sensitive than natural, perhaps more easily fatigued, and we can readily understand that this condition must be associated with some change in that part of the central nervous system which controls the nutrition and sensation in the joint; that this spot in the central nervous system will be more sensitive, more easily acted upon by irritating causes than other parts; that by the irritation the nerve cells in the part will be more easily exhausted, and therefore in rheumatic individuals this particular joint will be the one first affected, and perhaps solely affected, in all attacks of rheumatism. A most interesting case of "Inflammation of the Joints following Injury of the Spine," which is recorded in THE LANCET by Mr. Wherry,[15] illustrates, I think, very well the development of arthritic mischief from irritation of the central nervous system, the irritation chiefly localised in the medulla oblongata, and affecting the vaso-motor centre.

Dr. Dyce Duckworth, in an extremely suggestive and able essay,[16] contends that gout is a primary neurosis, and that the portion of the nervous system specially involved is situated in some part of the medulla oblongata. I hope that what I have advanced will tend not only to confirm this view, but also—to use the words of Sydenham, which he quotes—to clear up and explain some of "the difficulties and refinements of the disease itself."

(To be concluded.)

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—The thirty-seventh anniversary dinner in aid of the funds of this institution was held at Willis's Rooms on the 8th inst., the Duke of Connaught presiding. The hospital, established in 1848, contains accommodation for 164 patients, and, whilst its annual expenditure amounts to £10,000, its ordinary income does not exceed £3500. In the course of the evening the secretary read a list of donations and subscriptions, amounting to £2342, of which £1272 had been raised in the East-end of London.

Gulstonian Lectures

ON

SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

BY SEYMOUR J. SHARKEY, M.B., F.R.C.P.,
ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE III.

(Concluded from p. 730.)

III. FUNCTIONAL SPASMS.

THE result of our consideration of those diseases which produce many varieties of spasm, and which are represented by gross lesions of the nervous system is, that a very large proportion must be put down to the credit of the cerebral system of fibres, or pyramidal tract. The spinal mechanisms are less prolific causes of these affections; but those spasmodic conditions which do occur in connexion with them have been considered under the heads (1) Peripheral—Motor Nerves; (2) Afferent Nerves; (3) Centres. It is only reasonable to suppose that, if functional spasms resemble those which result from gross lesions, they may admit of a similar explanation. In nerves and muscles which during life have been the seat of motor disorders, we may find no naked-eye or microscopic pathological changes after death. But clinical observation shows that, so far as function is concerned, marked changes have occurred. Now we know that healthy function must depend upon fine molecular re-arrangements which are at present a closed book to us; and we conclude that, if molecular changes form the basis of healthy function, they form that of pathological conditions also. If this be so, it is legitimate to argue that the molecular changes in question might affect the same parts which are the usual seats of the grosser lesions, and consequently give rise to similar abnormalities of function; and then the anatomical classification which has already been attempted in the case of tangible disease might serve also for those cases which are the result of impalpable alterations in nerve and muscle. I propose, therefore, to consider shortly certain forms of functional spasm, and I shall use the same divisions for classification which I have already used for grosser diseases.

1. Do functional disorders of the cerebral motor mechanism, or pyramidal tract, produce spasmodic conditions at all resembling those resulting from gross disease? They do. In hysteria not only does hemiplegia occur, but hemispasm, both fixed and mobile, is not uncommon. There is this difference between the hysterical conditions and those which are seen in gross disease—the leg is affected most, the arm less, and the face not at all. But the facts observed in gross disease, where the leg is usually less affected than the arm, are probably to be explained mainly by the fact that the vessels which bleed most frequently and interrupt the functions of the internal capsule are those which are situated towards the anterior part of its motor division—that part, in fact, which contains the fibres controlling the face and arm. But apart from these points, the spasmodic contractions of the leg and arm are similar in the two conditions. In functional diseases there is simply removal of the voluntary impulses which, in health, travel down the pyramidal tract. The muscles and nerves of the limbs remain practically healthy, and if rigidity is not too great the tendon reflexes are increased. Fevers and other exhausting conditions—such, for instance, as that of the patient with anæmia to whom I have already referred—may give rise to increased reflexes, and even to clonus and rigidity. Moreover absence of portions of the motor area of the cortex, such as, is occasionally seen congenitally, is accompanied by non-development of the corresponding portion of the pyramidal tract, and gives rise to spastic conditions like those found in hemiplegia. Absence of the voluntary impulses, then, is enough to give rise to the phenomena in question; and certain cases of hysteria have died after long-continued contraction of limbs, and the most careful examination with the microscope has failed to disclose any palpable pathological changes. Such a case is recorded by Dr. Bristowe

Digitized by Google

in *Brain* for October, 1885. This case I often saw myself, and, as Dr. Bristowe remarks, "at the end of two years she seemed as well in general health as when she first came to the hospital; but she was suffering from headache, sickness, ophthalmoplegia externa, complete anæsthesia of the right side, with rigid paralysis of the arm and leg, and repeated hæmorrhages of both ears." Dr. Hadden made a most complete microscopical examination of the central nervous system in this case, but found no evidences of disease. As we know, however, that mere absence of the voluntary motor impulses along the pyramidal tract is sufficient to give rise to this condition, it is legitimate to conclude that suppression of the functions of this tract is the cause of functional hemispasm. We are still further supported in this view by cases like that just quoted, where there is at the same time clear evidence of suppression of the functions of the sensory area as well.

Clinical and pathological observation has shown that monospasms having similar characters may be produced by certain limited lesions of the motor convolutions; and after what has been already said, it is not too much to assert that when spasm limited to a leg or arm occurs in hysteria, it is due to suppression of the functions of the pyramidal tract, which in health controls the action of the affected member. In discussing the question of athetosis and other allied mobile spasms, we arrived at the conclusion that they were due to affections of the same tract of fibres, which were not severe enough to stop the passage of voluntary impulses. Now, similar conditions occur in hysteria, and may probably be explained in the same way. Weir Mitchell, in his work on Nervous Diseases, records cases of "hysterical motor ataxy" and of "hysterical athetosis." It appears probable that changes, ending in greater or less functional abeyance of the pyramidal tract, lie at the root of unilateral, and sometimes of bilateral spasm, both in functional and in gross disease. The only difference is that in the latter case we can appreciate by our present methods of investigation the alterations which have been wrought, while in the former they are hidden from our view.

There is another class of functional spasmodic affections which are hardly represented among the forms of spasm due to gross lesions, and which I believe have their origin in suppression of the functions of certain portions of the pyramidal tract. I refer to those conditions which are sometimes termed "professional hyperkineses." They include histrionic spasm, writers' cramp, pianists' cramp, telegraphists' cramp, &c. The striking peculiarity of these affections is that, when a voluntary effort is made to perform the accustomed muscular acts, spasm of the muscles involved occurs and prevents further efforts. Before this stage of the affection is reached great fatigue often accompanies endeavours to work. In a considerable number of cases, at any rate, the muscles can be employed in other ways without difficulty. What has occurred is probably that after long-repeated acts of the same kind that part of the pyramidal tract which is used gets fatigued, and its functions are partly suppressed, so that a condition of "latent contracture" of the muscles, over the voluntary actions of which it presides, is developed; the lower centres are "let go," as Hughlings Jackson says, and are in a state of "hyper-physiological activity," just as the spinal centres of one side are in hemiplegia accompanied by slight rigidity.

In describing "latent contracture" in connexion with hemiplegia from gross disease, Ross says: "The patient may perform all the simple movements of the limb, and probably with undiminished power; but when his attention is specially directed to the movements, as when he wishes to perform any manual operation requiring a little dexterity, the muscles instantly become rigid, the fingers are flexed on the palm, and the deformity which was present during the period of fixed contracture reappears." Surely this description suggests the true explanation of professional spasmodic affections, which present symptoms resembling very strikingly those which Ross portrays.

Erb divides the professional hyperkinesis into spastic, tremulous, and paralytic. The tremulous cases are perhaps due to similar but slighter paralytic affections of the pyramidal tract, and the condition probably resembles in kind though not in degree, paralysis agitans. The pathology of the latter disease is not known, but those cases which one meets with where rigidity of the limbs and exaggerated reflexes occur, suggest forcibly degeneration in the pyramidal tract as the physical basis of the affection. The paralytic variety of the professional hyperkinesis is probably the result of extension of disease to the motor cells in the anterior cornua of the cord, at any rate in those cases where marked atrophy occurs[1]. I should remind my hearers, in passing, that the term "pyramidal tract," as used here, includes not only fibres but the motor cells of the cortex in which they originate.

2. We have seen that spasm of muscles resulting from gross disease of the pyramidal tract has its representative among functional diseases; let us now consider that which owes its origin to affections of peripheral motor nerves. Is it likewise represented among functional disorders? Actual gross pathological changes in motor nerves give rise to muscular spasm, as has already been pointed out, in two ways—the one direct, and the other indirect. In the latter case, certain muscles atrophy and disappear, and, undergoing cicatricial shortening, produce distortion; or else their opponents, being left to act in their absence, give rise to abnormal positions of the limbs. Now, one of the striking peculiarities in functional nerve disease is the absence of such degeneration and destruction of muscles. Hence we should not expect to find any functional spasms which were due to such indirect causes; nor do we, so far as I know. We also came to the conclusion that direct irritation of motor nerves is a very rare originator of spasm; and there is no reason to suppose that it is less rare as a cause of functional affections. Nerve centres seem much more prone than nerve fibres to functional disorder. I am not sure that the latter condition, originating in centres, may not so affect even peripheral nerves which are connected with them as to give rise to symptoms which are found in gross disease only when peripheral nerves are involved. Dr. Norris, of Windsor, sent a girl, aged sixteen, to me for treatment in the hospital, who had lost the use of her left hand for eighteen months. She was a strong, healthy girl, and free from evident hysterical tendencies. The affection commenced with swelling and blueness of the fingers, such as is seen in chilblains; and the hand was cold and numb. When she came to me the hand was completely paralysed and had a swollen puffy look; the skin was paler and smoother than that of the right hand, and the backs of the fingers far less wrinkled. The left hand was much more influenced by external conditions than the right, and rapidly became warm when covered and cold when exposed. She got suddenly well after the application of a blister to the wrist, but then lost power in the left leg; the latter also suddenly recovered power. But although slight alterations, such as those which were observed in this patient, may occasionally occur in peripheral motor nerves in cases of functional disease, I am not aware that they give rise to muscular contraction.

3. Nor is there any proof that chronic spasm is produced by molecular changes of afferent nerves alone. Even in gross disease of an afferent nerve giving rise to reflex spasm, the lesion is often so trivial as to make it very probable that functional disorder of the centres is present as well, and is the main factor in the production of spasm. When speaking of reflex spasm from gross disease, I pointed out certain cases of what appeared to be rhythmical spasm due to affections of tendons; and I cannot help thinking that this class has frequent representatives in functional diseases. But they are due more to the abnormal condition of the centres than to that of the peripheral nerves. There can be no question that one of the peculiarities of nerve centres in hysteria is their abnormal irritability; so that slight afferent impressions give rise to muscular acts, which pass with great ease into neuro-muscular habits. Such a condition is well exemplified in cases due to imitation. The patient sees a certain form of muscular spasm, and the idea produces the same in her. For instance, a healthy girl, aged seventeen, came to my out-patient room complaining of involuntary movements in her right hand and tongue. On examination, it was seen that the thumb was rhythmically adducted, and there was simultaneous flexion of the fingers, most markedly of the index-finger, which moved in such a way that she appeared to be rolling something between it and the thumb. At the same time she was troubled by being suddenly unable to finish a sentence, owing to the tongue refusing to act properly. The girl worked in a confectioner's shop, where one of her comrades became affected with uncontrollable movements in the left hand and catching in her

[1] See Brain, vol. vi., p. 233: "A case of Sawyer's Cramp," by G. V. Poore, M.D.

Digitized by Google

speech. After a short time my patient became similarly affected.

The following is another case of suddenly developed neuro-muscular habit, though it originated in a somewhat different way. A healthy, dark-haired girl of sixteen, who had never had any illness, and had no evident neurotic peculiarities, went for a row on the Thames with some friends in the summer of 1885. She rowed without much intermission for five hours, which was to her quite an unaccustomed length of time for such recreation. She used to row every morning at Wandsworth, where she was at school, but only for an hour at a time. About an hour after returning from this long row her arms began to twitch, and movements continued uninterruptedly, and remained of a precisely similar kind, up to Dec. 29th, 1885, when Dr. Bristowe, under whose treatment she had been, very kindly asked me if I should like to see her. Both arms were the seat of similar and synchronous movements occurring regularly about 160 times a minute. They consisted of rapid elevation and retraction of the arm at the shoulder and of the scapula, partial flexion at the elbow, and slight extension of the wrist; in fact, they bore a very marked resemblance to the movements of the arms and hands in rowing, the extreme rapidity of the "stroke" making up for the limited extent of the movements. In these rhythmical contractions it is not at all improbable that the slight stretching of the tendons of the affected muscles which naturally results from the action of their antagonists gives rise to another contraction, and so on for an indefinite number of times. Such a condition, though much less marked, is sometimes seen when the spinal centres are cut off from connexion with the cerebral cortex by gross disease.

A case of caries of the cervical vertebræ was under my care in St. Thomas's Hospital last summer, in which paraplegia with rigidity had been present for five years. The legs were always flexed at the knee and hip, but could be extended by continuous gentle traction. As this was being performed, movements of flexion and extension, which were involuntary, occurred. When the tendons of the flexor muscles were stretched, the latter contracted, and in so doing they put the extensor tendons on the stretch and so caused their contraction. Weir Mitchell has noticed these "alternate spasms" in hysteria, in which, as he remarks, the action of the flexors calls the extensors instantly into play, and this, in turn, summons the flexors into activity. "These spasmodic motions," says he, "were the more curious in the last case I saw, because of the general and profound paresis, which made every volitional effort excessively difficult." Such an absence of voluntary power in the case of which Weir Mitchell speaks shows that the functions of the cortical motor centres were in abeyance. Instances of alternating spasms are far from rare in hysteria, and probably owe their presence to excessive irritability of the spinal centres, and the development of a habit through the intermediation of tendon reflexes. "Saltatory spasm" is a good instance of this class of cases.

4. The fourth and final heading under which we have to compare spasmodic conditions arising in connexion with gross nerve lesions, with functional disorders, is disease of the spinal motor centres. We have already seen that tangible pathological alterations in these cells give rise to paralysis and subsequent atrophy of muscles, but we could quote no facts to show that muscular spasm ever originates from such disease. Those impalpable molecular changes which result from the anatomical separation of the cerebral motor centres from the spinal centres produce a condition of hyper-physiological activity of the latter, to which many spastic conditions are due. Does abnormal functional activity ever exist primarily in the spinal centres and result in spasm? This is a question which is very difficult to answer. In the case of gross lesions which interrupt the continuity of the pyramidal tract fibres, even where no actual spasm has resulted, there exists a condition of excessive excitability of the spinal centres, which gives rise on the slightest provocation to rigidity of muscles. An injury, even of a trivial nature, may in such cases produce contracture. Exactly the same state of things is found in hysterical subjects; and Charcot, in his lectures on Nerve Disease, gives instances of the most trifling injuries suddenly producing spasmodic conditions of limbs in such patients. But we must remember that persons may have those peculiarities of their nervous system which are usually embraced under the term "hysteria" without ever presenting striking emotional or other tendencies which are wont to call attention to the existence of the disorder. The first evidence of the latter may be the sudden supervention of spasm from a very slight external injury. If this condition of the spinal centres depends mainly upon the amount of cerebral control exerted over them by the functional activity of the pyramidal tract, it is evident that there must be infinite gradations between the normal and abnormal. Indeed, it is impossible to give any strict definition of health and disease. All we can say is, that the more cerebral control retires into the background the more likely are spasmodic conditions to come to the fore.

It is quite impossible to answer the question, whether hyper-excitability of the spinal centres occurs in the absence of diminution of cerebral influence to account for it; but it probably does. We know that strychnine, in certain doses, produces an excitable condition of the spinal centres, which Charcot has likened to that which is seen in "latent contracture" due to gross lesions of the pyramidal tract, and to hysteria. In comparing strychnism with the latter, Weir Mitchell says:[2] "Perhaps I shall in a measure clear your minds as to the nature of what I mean by functional spasms if I recall to you the influence of strychnine in large doses, such as you have seen given here many times. You will remember that, in certain spinal maladies, such as those of syphilitic birth, it is my habit first to give iodides in heavy doses, then to suspend them for a time, and to give strychnine up to the limit of physiological endurance—that is to say, until I cause an approach to spasm. When, for example, you give hypodermically from one-fifth to one-eighth of a grain daily, the patient will have little or no annoyance, if you are careful to insist that he remain at absolute rest in bed for two hours after each injection. If there be any tendency to spastic twitchings of the muscles, the will is competent to control them, unless—and this is the point I would make—the patient attempts to exercise. Should he do this, the effort results at once in irregular movements of an incoördinate character, and in slight or more grave spasms of the muscles employed. While at rest there is no obvious trouble, but voluntary movement occasions spasms, which are the offspring of the poison. They are, in a word, functional spasms, and would not be seen at all with a limited use of strychnine, were it not for the efforts of voluntary action." If, then, a substance circulating in the blood can directly produce this condition of the spinal centres, in which they may almost be said to be watching their opportunity to produce muscular contraction, it is not improbable that molecular alterations may arise from other causes, and produce a similar excitable condition of these centres. We know, however, little, if anything, about the changes which act thus. What are called phantom tumours of the abdomen, and sometimes of other parts, may have some such origin; Weir Mitchell records one in which all the abdominal muscles had remained violently contracted for a year. But whether this be the explanation of such cases or not, the hyper-physiological activity, due to lack of cerebral control, which exists in the spinal centres of some subjects, is probably the principal factor in a very large number of tonic and clonic functional spasms.

In the comparison which has been attempted between the results of gross disease on the one hand, and molecular or so-called functional alterations on the other, the pyramidal tract stands prominently forth as the greater offender in the production of muscular spasm. Its action is indirect, it is true, as it only looses the reins of the spinal centres, which it should keep well in hand. Still, it rules the situation. Spasm rarely ensues directly from injury or disease of peripheral motor nerves, and although it frequently results from reflex causes, it is very likely that the spinal centres are, in a considerable proportion of cases, more at fault than the afferent nerves. It may be thought somewhat curious that, in speaking of diminution of cerebral control, the voluntary motor tract should alone have been referred to as liable to suffer from depression of its functions. But the only reason why it has been thus signalled out is that these lectures have dealt with motor phenomena. The sensory functions of the brain suffer, too, in a very striking manner, so that complete hemianæsthesia is far from a rare occurrence in hysteria, the loss of function being evident in the realm of the special senses, as well as in that which has to do with common sensation. And although at first sight these functional defects appear to be confined to one side,

[2] Lectures on Diseases of the Nervous System, especially in Women p. 100.

Digitized by Google

careful investigations show that they are not. For in cases of hemianæsthesia, both fields of vision are contracted, although that on the anæsthetic side is the most affected. Again, in cases where the loss of function appears to be confined to the sensory area, a careful comparison of the muscular power on the two sides will show that this is not so. In a case of the kind which I lately saw, I found that on the hemianæsthetic side the patient could only reach 45 on the dynamometer scale, although this was the right side, while with the left she reached 50. In such hysterical patients it is probable that nerve power is deficient in all parts, and on both sides of the brain, although this deficiency is more marked on one side than the other, and more so in some portions of that side than in others. Considering how late the pyramidal tract develops in man, and what a high pitch of evolution it represents, it is not to be wondered at if it is one of the first parts to suffer in the process of dissolution.

If we are right in considering deficient nerve power, especially in the brain, as the condition which is at the root of functional nerve disease, the term "neurasthenia," a product of modern times, would be a more suitable general title for such disorders than the older term, "hysteria." When we review the history of nerve disease in families, we cannot but conclude that people are born with very different physical bases both in their nervous and other systems; and no line can be drawn between those that are normally stable and enduring under unfavourable circumstances, and those who are liable to lose equilibrium. Some patients would remain perfectly well had they not accidentally met with some catastrophe, and then they get into the category of hysterical patients. And yet there are many of their friends and acquaintances who are as liable to functional disorder as they are, and who yet may never have their weakness brought to light, owing to their not having been exposed to a sufficiently severe trial. Even small portions of nerve centres may become hysterical, if I may be allowed to say so—as, for instance, in writers' cramp, pianists' cramp, and other professional hyperkineses. All that we know of this matter is, that functional nerve disease, even in the case of apparent exceptions, such as spasm, is due to deficiency of nerve power. How the condition is actually brought about we cannot tell. Some think the centres are starved by contraction of their nutrient vessels. It seems to me more likely that the nerve centres are exhausted by their own action. Thus, sudden emotional excitement may bring on hysterical phenomena, indicating nerve exhaustion, such as hemi-anæsthesia, paralysis, or spasm. It is important to remember, too, that exhaustion of one arena seems to affect the whole system. This may indicate that the various differentiated centres draw nerve force from some common supply. Considering the enormous amount of cells which are found in the cerebral grey matter, many without evident connexions, is it going too far to suppose that a large number of these are factories for the production of nervous energy, which is necessary for the continuous and regular action of the highest centres, and which flows in increasing quantities towards those centres which are from time to time brought into action? Constant supply would mean constant power in all centres; and as the latter are all bound together so as to produce a physiological equilibrium, constant power would involve constant control of one by the other. Where the store of constantly produced force (represented, of course, by structural peculiarities) is by inheritance small, or where it has been exhausted by unnatural calls upon it, there would be insufficient to supply all the centres, and those to which the nerve paths are most freely open by habit would command it, while others would be starved, and loss of equilibrium, or the natural control of one centre by the healthy action of others, would be the inevitable result. If we do not suppose any such reservoir of nerve energy, how can we explain the exhaustion of all by the excessive action of some centres? Why is a person who has had excessive mental work less able for the time to do active bodily work? and why when bodily fatigued are we less ready to do intellectual work?

But I have gone, I fear, too far into a region of speculation, which it is hardly legitimate for me to have even entered with so small an equipment of facts. I shall therefore say no more, but bring these lectures to a conclusion by offering an apology for having chosen a subject which is so extensive in range, and at the same time so obscure and little understood, that my treatment of it must fall far short of that which is expected on occasions like the present.

ON AN

IMPROVED OPTOMETER FOR ESTIMATING THE DEGREE OF ASTIGMATISM AND OTHER ERRORS OF REFRACTION.

BY JOHN TWEEDY, F.R.C.S. ENG.,

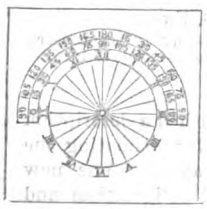
PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY IN UNIVERSITY COLLEGE, AND SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

ABOUT nine years and a half ago I published a description of a cheap and simple form of optometer for estimating the degrees of astigmatism.[1] Since then at least one new method of ascertaining the existence of astigmatism and estimating its amount has been introduced, and many improvements have been effected in the older methods. The novel plan is that which was first employed by M. Cuignet of Lille, and is commonly called keratoscopy or retinoscopy.[2] The introduction of this method has had almost as great an influence upon ophthalmic practice as that of the ophthalmoscope itself. It is at once simple, certain, and *objective*, and in the majority of cases it is sufficiently precise. In young children it is almost the only available plan. There are, however, some conditions in which it is less applicable—such as nebula, or leucoma, or irregularity of curvature of the cornea, small pupil, anterior or posterior synechia, uvea on the capsule of the crystalline lens, haziness of the lens itself or of the vitreous, or a darkly pigmented fundus. It is true that many of these disqualifications may be removed by the use of atropine or other mydriatic. But there are not a few objections to the indiscriminate employment of mydriatics for working out errors of refraction. The temporary abolition or embarrassment of the power of accommodation for some hours, or even days, is by no means the worst of these objections. At least two cases have lately come under my observation in which a solution of atropine applied to the eyes for the purpose of dilating the pupil in order to facilitate the estimation of hypermetropic astigmatism by retinoscopy very speedily gave rise to an outbreak of subacute glaucoma in both eyes. Even without this untoward experience, I have always, as far as possible, endeavoured to avoid using mydriatics for the purpose of estimating errors of refraction, but especially in hypermetropes, in whom the tendency to glaucoma is greater. In all cases in which retinoscopy is difficult, or where great precision is desirable, other methods must be employed. Personally, I prefer Green's tests or my own optometer. With the latter I can in most cases obtain trustworthy results without the use of atropine, though in some instances the result is only approximately correct. But this objection applies to any other single plan or to any combination of plans. In difficult cases it is, therefore, always well to employ at least two different methods, each corrective or confirmatory of the other.

Though the optometer which I now employ is in principle the same as that which I originally described, I have from time to time introduced modifications calculated to increase its efficiency. These modifications have, however, never been formally described, but have been for the most part suggested to various opticians and instrument-makers, who, wishing to copy the optometer, have asked me for information about the working out of some of the details. The chief modifications are—(1) a graduation of the horizontal bar, in accordance with the dioptrical system; (2) an improved dial card; and (3) a vertical bar of adjustable cylindrical lenses. These may be more particularly but briefly described.

(1) Since the year 1879 the horizontal bar has been divided on its upper surface not only into inches and tenths, but also into *focal lengths* of dioptrical lenses and quarters, from three dioptres to forty. These focal lengths I call *dioptrostads*.

(2) The radiating lines on the dial card are indicated not only by the Roman numerals I. to XII., but also by a double row of Arabic numbers. Each number of the lower row records the angle which the corresponding line makes



[1] THE LANCET, Oct. 28th, 1876.

[2] For an excellent account of so-called "retinoscopy," see article by Dr. Charnley, Royal London Ophthalmic Hospital Reports, vol. x., p. 344.

Digitized by Google

with the horizon, beginning from the left; and each number of the upper row serves the twofold purpose of indicating—first, the line which is at right angles to its fellow in the lower row; and, second, the position of the axis of the correcting cylindrical lens. (Fig. 1, and Fig. 2, *j*.)[3] For example, the line at right angles to 135°, running from between I. and II., is seen to be 45°, which will be found to run from between X. and XI. As the two principal meridians of the eye in regular astigmatism are at right angles with each other, it follows that if the line 135° be in one principal meridian, the line 45° will be in the other principal meridian, and so for every other line. The radiating lines may be fine and of equal thickness throughout, or, preferably, they may gradually increase in thickness from the centre to the periphery, as in one of Green's astigmatic disks.

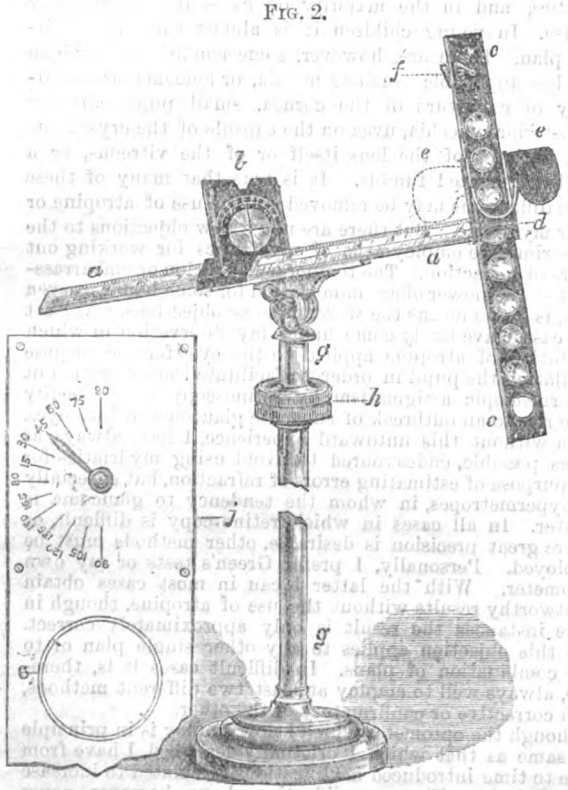


FIG. 1.

Reduced rather more than one-half.

(3) I have always recognised the advantage of having cylindrical lenses affixed to the instrument, but for a long time there seemed no way of carrying this into effect except by a disk like that on Javal's original optometer. To any such arrangement I have always objected, chiefly for the reason that the disk prevents the eye under examination from getting close to the instrument, and compels the patient to twist the head to look out of the outer canthus. Both these conditions tend to vitiate the result. The difficulty has at length been overcome by using a vertical bar of concave cylindrical lenses. (Fig. 2, *c* and *j*.) By a simple arrangement, worked out, now more than eighteen months ago, by Messrs. Pillischer of New Bond-street, all the cylinders may, by turning a tap (*f*) be rotated simultaneously, so that the axes of all the cylinders are always parallel. The cylinders are set by making the indicator on the plate (*j*) point to the number which on the dial card is in the upper row opposite the line most clearly seen at the greatest possible distance in the examination about to be described. The axes of all the cylinders will then be at right angles with this clearest line. The concave cylindrical lenses contained in the vertical plate are 0·5, 1·0, 1·5, 2·0, 3·0, 4·0, 5·0, and 6·0 dioptres. It would be easy to increase the number so as to have finer gradations, but practically these are enough. If, for example, 2·0 D were not enough to correct the astigmatism, while 3·0 D over-corrected, it is clear that 2·5 D would be within 0·25, or $\frac{1}{100}$th of an inch of perfect correction.

FIG. 2.

The optometer should be used in the following way: 1. A convex lens having been slipped into the clip at *d*, in order to make the eye about to be examined artificially short-sighted, the eye is placed as close as possible to this lens and made to look, with head erect, straight through its centre at the dial card beyond on the plate (*b*). (See also Fig. 1.) The lens (myopising lens) which will be required will vary with the refraction of the eye. It is best to select a lens which brings the far point to about 8 in., or 5 *dioptrostads* from the eye. In hypermetropia 8 D to 12 D, or even more, may be required; in myopia 1 D to 3 D may suffice; and in high degrees of myopia—that is, more than M = 8 D—no lens will be needed. The opposite eye should be excluded by the screen (*e*). The height is adjusted by means of the telescopic stem (*g*) and the screw collar (*h*) 2. The dial plate (*b*), placed at first beyond the point of distinct vision, is slowly approximated to the eye until at least one of the radiating lines is seen *clearly and distinctly* throughout its whole length. After this the plate should not be moved, and its distance from the eye should be noted in dioptrostads (δ). Under the circumstances the line is seen at the greatest distance from the eye, and therefore in the principal meridian of *least curvature*.

If *all* the radiating lines come into view with equal clearness at the same greatest distance, there is no astigmatism; but if *one or two* lines be clearly seen, while the others, and especially those at right angles to them, are blurred, there is astigmatism, which may be corrected by placing a suitable concave cylindrical lens in front of the eye, with its axis at right angles to the clearest lines. The suitable lens is the weakest which makes all the lines equally clear. This is ascertained by sliding the vertical bar of cylindrical lenses, properly adjusted, in the groove at *d*, till correction is accomplished. The weakest cylinder that will do this represents the *amount* of astigmatism.

This completes the examination. It only remains to interpret the results.

1. As already stated, if *all* the radiating lines come into view at the same greatest distance there is no astigmatism. (*a*) If the greatest distance in dioptrostads (δ) equals the number of dioptres (D) in the myopising lens, there also is no other error of refraction: $D = \delta$. (*b*) If the greatest distance have *fewer* dioptrostads than there are dioptres in the myopising lens, there is hypermetropia equal to the difference between the two: $H = D - \delta$. For example: If D have 8 dioptres and δ 5 dioptrostads, then the hypermetropia will be 8 − 5, or 3 D, and the patient will require a correcting lens of this strength. (*c*) If the greatest distance have *more* dioptrostads than there are dioptres in the myopising lens, there is myopia equal to the difference between the two: $M = D - \delta$. If D be 5 dioptres and δ be 8 dioptrostads, M = 5 − 8, or −3. D; and the patient will need a concave lens of this strength.

2. If only *one line or two lines* are clearly seen at the greatest distance, there is astigmatism. The refraction of the meridians in which these lines are seen will depend upon whether the distance at which they are seen be *beyond* or *within* the focal length of the myopising lens, as shown above; $x = D - \delta$. (*a*) The astigmatism is, as already stated, represented by the *weakest* concave cylindrical lens which set at right angles to the clearest line makes all the lines clear. (*b*) The correcting lens for distance will be the combination of the spherical lens found by the above formulæ and the weakest concave cylinder which corrects the astigmatism. If $D = \delta$, no spherical lens will be needed, and the cylindrical lens alone will suffice; if D be greater than δ, a convex spherical lens will be needed in addition; and if D be less than δ, a concave spherical lens.

[3] Optometers containing most of the improvements in the marking of the bar and in the card were, I believe, first made by Messrs. Pickard and Curry, of Great Portland-street, about six years ago.

AT the annual meeting of the governors of the Princess Frederica's Convalescent Home for Married Women, at Hampton Court, on the 16th inst., a highly satisfactory report was presented. During 1885 the annual subscriptions and donations had considerably increased, the total income for the year amounting to £796.

THREE EPOCHS IN MEDICINE.[1]

BY M. CHARTERIS, M.D.,
PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, GLASGOW UNIVERSITY.

GENTLEMEN,—In this concluding lecture I desire to briefly draw your attention to certain facts connected with the history of medicine which stand boldly out as means for averting disease and death. I allude to three epochs: (1) Vaccination; (2) Antiseptics; and (3) Hydrophobia. I am induced to do this because we are at the present moment passing through the third epoch, the results from which seem to be very momentous and far-spreading. To a great extent these epochs are distinguished by circumstances obscure in their origin and deduced from observations of common life. All men can see the sun, the moon, the stars, the sea, and the wide expanse of earth, but it requires the man of genius to raise these, as it were, from their surroundings and enhance them by the beauty of song and verse. This idea is revealed notably by the incidents which led up to Jenner's great discovery.

Jenner was a distinguished student in London, and had the privilege of the friendship and instruction of John Hunter, yet he settled in a country practice, and, notwithstanding great inducements, never forsook the field of his early labours. He cared not for fame, for he lived for mankind. Thus he simply states when requested to go to London and make his fortune, "Shall I, who even in the morning of my days sought the lonely and sequestered paths of life, the valley and not the mountain—shall I now, as my evening is fast approaching, hold myself as an object for fortune and for fame? My fortune from what flows from my profession is sufficient for my wants; and as for fame, what is it?—a gilded butt for ever pierced with the arrows of malignancy." As Jenner rode or walked on his daily rounds through one of the most fertile of English country districts, he meditated much on disease, and particularly on that disease which spared neither sex nor age, and which, when not fatal, rendered its victim for the future unseemly and pitted. Small-pox was a dreaded scourge, recognised as the hereditary curse of mankind, and as an inheritance which neither time nor medicine could remove. The practice of inoculation introduced by Lady Mary Wortley Montagu robbed it of some of its terrors, for small-pox so imparted gave rise to a milder form of disease, and there was little if any chance of a fatal issue. But small-pox perpetuates small-pox. All were not inoculated, and in proportion as inoculation was actively undertaken the centres of contagion were multiplied and almost every home was converted into a hospital. Inoculation therefore did not diminish—nay, it actually increased the mortality from small-pox. Country gossip averred that milkmaids who contracted cow-pox when they handled the teats of diseased cows were not afterwards attacked by small-pox. It was only gossip. It might be an idle tale. Many men had heard it before and scouted the idea. It was not so with Jenner. He investigated the matter, and step by step, not in a day, or a week, or a month, or even a year, but after he was forty-nine years of age, he was led to formulate his conviction "that in a certain condition the pustule imparted its protective power to the human constitution." It was, moreover, a protective power from disease in its most repulsive form. Around small-pox there are no æsthetic qualities, no fair features, which in some cases of illness seem to purge away the grosser clay and leave in death's embrace an image pure and bright. The sick room in small-pox is permeated with a loathsome odour from the ripe pustules; the face is swollen, the eyes closed, and in the bloated countenance no gleam of intelligence rests. Yea, even a mother's love I have seen recoil from such a spectacle. The country surgeon, the middle-aged man, was lost in reverie, for he foresaw that in future years this terrible affliction would be removed from the human race, that the lines of beauty would never be scarred, and that glad mothers in every land would bless the name of Edward Jenner. No wonder, when this prospect brightened before him, he wrote: "While the vaccine discovery was progressive, the joy I felt at the prospect before me of being the instrument destined to take away from the world one of its greatest calamities was often so excessive, that, in pursuing my favourite subject among the meadows, I have sometimes found myself in a kind of reverie. 'Tis pleasant for me to recollect that these reflections always ended in a devout acknowledgment to that Being from whom this and all other mercies flow." The progress of vaccination was rapid. It was adopted in America, India, and other colonies, and the continental nations hailed it with delight. Honours flowed upon Jenner. Napoleon had a medal struck in commemoration of the discovery, and presents in money were forwarded to him from the capitals of our Indian presidencies. A touching tribute was sent by five native Indian tribes in America, in which they said: "We shall not fail to teach our children to speak the name of Jenner. We send with this a belt and a string of wampum in token of our acceptance of your precious gift, and we beseech the Great Spirit to take care of you in this world and in the land of spirits."

When I was a student in Edinburgh Joseph Lister lectured on surgery as an extra-mural teacher, and we were not then impressed with his abilities. He was slow and hesitating in his speech, spoke with diffidence, and as an operator lacked dash and rapidity. He was, however, the son-in-law of Syme, and he had possibilities which he has since worthily fulfilled. Appointed to the Chair of Surgery in this University in 1864, he was also made a surgeon in the Royal Infirmary, and in this latter sphere he evinced those thoughtful qualities which have rendered him famous. The surgical hospital of the infirmary was unhealthy, as well it might be, for circumstances afterwards showed it was built on a charnel-house. Behind the lowest male accident ward, a few inches below the ground, with only the basement area intervening, there was found on investigation the uppermost tier of a multitude of coffins, which had been placed there at the time of the cholera epidemic in 1849. The result of this proximity to the ward was evidenced by the fact that compound fractures with open wounds always assumed a bad type and developed pyæmia. Measures were adopted to remedy this nuisance, and were successful. Yet from this polluted atmosphere Lister apprehended how germs aided putrefaction, and subsequent experiments which he made on animals, under antiseptic precautions, showed no trace of putrescence. Based on these facts, he proved that wounds by accident or resulting from surgical operations could be rendered clean and wholesome. Lister did not, however, rush into print with the information all at once. Not until he had carefully satisfied himself on every point, and until conclusive evidence had been accumulated, did he publish his observations in THE LANCET. The sensation produced was marked. It evoked a new era of surgical practice. It surprised and fluttered the timid dwellers in the peaceful dovecots of orthodox routine surgery. Their wonder was intense when they learned how from the odour of a cemetery, round which the slimy Molendinar creeps, a Glasgow professor and a hospital surgeon deduced correctly the antiseptic process of treating wounds. So carefully founded on fact were his conclusions that the surprise deepened into gratitude, and they were accepted without much cavil. THE LANCET thus summarised the importance of the discovery: "If Professor Lister's conclusion with regard to the power of carbolic acid in compound fractures should be confirmed by further experiments and observation, it will be difficult to overrate the importance of what may be called his great discovery. For although he bases his surgical use of carbolic acid upon the researches of M. Pasteur, the application of these researches to the case of compound fractures, opened abscesses, and other recent wounds is all his own." The great characteristic of Lister is his thoroughness. He assumes nothing. He tests the experiments of others. He is open to conviction, and he is never dogmatic. In a word he is a man to be trusted, and hence he occupies a unique position in the scientific world. As a lecturer he greatly improved after he was appointed to this University. His voice was carefully modulated. He never spoke quickly; always distinctly; repeated when necessary his sentences to emphasise his lectures. In 1874 he dedicated to Pasteur his "Researches on Antiseptics," which he says, "for the last nine years I have been trying to bring to perfection. Allow me to take this opportunity of sending you my most cordial thanks for having, by your brilliant researches, demonstrated to me the truth of the germ theory of putrefaction, thus giving me the only principle which could lead

[1] Lecture delivered at the conclusion of the winter course on Therapeutics at Glasgow University.

to a happy end the antiseptic system." Pasteur, it is stated, received this dedication with the most lively satisfaction.

We are living at present in the epoch of the cure for hydrophobia introduced by M. Pasteur. The principle of his method is as follows. The saliva of a rabid dog is the usual medium of communication to a human being. The dog bites and by the insertion of the saliva into the flesh, the poison is introduced. By the blood it is carried to the nervous centres of the brain and spinal cord, and after a certain length of time symptoms of hydrophobia are developed. If now a portion of the brain or spinal cord of a rabid dog is placed after trephining under the dura mater of a rabbit, rabies will develop in the rabbit as a rule after an average incubation of about fifteen days. But the virus so communicated can be intensified in virulence. By the same method the virus from the first rabbit is communicated to a second, from the second to a third, and so on until at the end of the fiftieth inoculation the incubation period is only seven days. The spinal cords of these rabbits are thus rabid throughout their whole extent, with a constant and definite degree of virulence. From one of these rabbits the spinal cord is taken, with due antiseptic precautions, and is suspended in dry air. The virulence, slowly disappearing, is finally extinguished. In this way the cords of rabbits can be had at a different stage of virulence. Soup of a certain kind is mixed with a fragment of cord, not in a very virulent state, and is injected under the skin of a dog. After an interval usually of two days, injections from more recent, and therefore more virulent, cords are used, until a time is reached when a portion of a very virulent cord is injected—i.e., of a cord which has only been kept in the dry air for a day or two. What is the result? The result is that the dog is completely protected. No symptoms of rabies can be produced either by the direct bite of another rabid dog or by injection of rabid matter. Pasteur so experimented with fifty dogs without a single failure, and then he justly considered he could test the experiment on a human being. On July 6th, 1885, an Alsatian boy (Joseph Meister) was brought to his laboratory who had undoubtedly been bitten by a rabid dog, and whose condition was such as to justify the supposition that hydrophobia was incubating in his system. Half a syringeful of a cord that had been kept for fourteen days was injected on the 6th, and on succeeding days injections were made from cords which had been kept for shorter periods, until at the end of ten days half a syringeful was injected of a cord which had only been kept one day. The 6th of July, 1885, was therefore the birthday of the cure of hydrophobia.

It may interest you to know what kind of a man Pasteur is. I was fortunate enough to see him at the last International Medical Congress in London in 1881, and to be so near him that I remember well his physique. He walks with a slight limp, for he once had an attack of hemiplegia due to continuous nervous strain from prolonged examinations with the microscope. He is about middle height, and rather stouter in his development than Frenchmen usually are; his head is massive, and planted on broad shoulders; his eyes are yellowish-brown; his forehead markedly wrinkled; his face full, and his beard short, scant, and grizzled. The whole appearance of Pasteur indicates decision of character, and his career shows that he pursues science from no selfish or pecuniary motives. His laboratory or hospital is open to the inspection of all duly qualified medical men. He exacts no fee, and he courts inquiry of anti-vivisection views. When men, or rather ladies, scoff at his present efforts, they should remember that Pasteur has a character to lose, for he discovered the cure for the silkworm disease, for splenic fever, for fowl cholera; that he defeated the great chemist Liebig in the assertions he made about acetic fermentation; and, further, that in all his researches his strongest wish has ever been to benefit his fellow-men. In a public assembly he uttered these remarkable words when upbraided for cruelty: "I never had the courage to kill a bird in sport, but when it is a question of experiment I am deterred by no scruples. Science has the right to assume the sovereignty of its aims."

Pasteur's treatment of hydrophobia is as yet *sub judice*, but we must all hope that the Royal Commission lately formed to investigate the matter will be able to give a highly favourable report. If Pasteur's idea is true, there is no doubt it has a wide applicability. It is simply the conception of Jenner carried out in another form. Attenuate the virus of small-pox and you destroy the fatality and virulence of variola. Inoculate other animals with the poison of rabies, and from this weakened virus safety seems to be secured to the bitten sufferer if recourse to the proceeding is effected in time. Go further; why remain content with small-pox and hydrophobia? Every seventh death in our country is due to phthisis in some form or other. A child from a phthisical parent, in nine cases out of ten, will, in his growing youth or mature manhood, be attacked by tubercle. That statement is about as certain as any yet made on the etiology of disease. Koch's bacillus stamps a peculiar identity on tubercle, and this bacillus can be isolated and cultivated. It does not originate, but its imprint is a true and unfailing sign of, pulmonary phthisis. Inoculate rabbits or guinea-pigs with this bacillus, and from these inoculations let hereditarily tainted consumptive patients be vaccinated before the constitution is sapped and its vigour impaired. It is a possibility that a safe and simple course of tuberculosis would follow, as safe and perhaps as simple as the vaccine vesicle of childhood, and complete immunity in after-life from the disease might be the result.

It is a painful and humiliating fact that now all original investigations are checked in Britain. We read of Pasteur's work. We cannot accredit or discredit it. We are surrounded with such careful legislation that not a guinea-pig or a rabbit can be sacrificed by a scientific inquiry without the licence of the Home Secretary. If we apply for the licence, we are asked why it is wanted. Is it for idle curiosity or to enlarge the sphere of knowledge? We are considered bloodthirsty men, and we are supposed inhumanly and wantonly to torture the lower animals. A more unjust charge was never made against a noble profession. The examples I have indicated show how humanity has been benefited by the efforts of these men. Advancing science cannot be stayed by odious whisper or sensational laws. Able and enthusiastic workers are ready to take the field in this country to expiscate facts from the domain of credulity and conjecture. Great is truth, and it will prevail, and I venture to say, before a decade passes, that the generous instincts of our newly enfranchised countrymen will sweep away from us every trammel which impedes honest experimental research having for its only object the relief of human suffering. Let us appeal as a profession from sentimental Cæsars to the people whose weal we desire; and let us ask with united voice that the land of Jenner, of Hunter, and of Lister should be as free for scientific inquiries as that of Pasteur and Virchow. Then, and not till then, will our true position among nations be resumed—a position which is ours by right from the mighty men renowned in medicine and surgery and allied sciences which this country has produced, and of whom we are justly proud. We will then lead the way.

CAN PNEUMONIA OCCUR AS THE DIRECT RESULT OF EXTERNAL VIOLENCE?

BY OCTAVIUS STURGES, M.D., F.R.C.P.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN.

IT is no very rare experience to find pneumonia and bodily injury in near association, yet the precise nature of the relationship is still open to dispute. At the present time, when the pathology as well as the causes of this disease are being sought out from a wider field than heretofore, the question with which I have headed this paper has something of new interest. On this account the case of a child lately admitted into the Hospital for Sick Children under my care is worthy of record. It illustrates some of the difficulties that beset us in a correct interpretation of facts, and gives occasion for a brief review of existing opinion upon this subject. The following narrative is abridged from very full and careful notes taken by Dr. Thomson, house-physician.

Charles T——, aged eleven, an ill-nourished, pigeon-chested child, dirty and neglected, was admitted to the Alexandra ward on the morning of Jan. 9th. He was much collapsed, the face pale, and extremities cold and clammy. The breathing was very shallow and rapid; respiration 50. Pulse 176, regular and very compressible; temperature 103°. Lips and tongue dry and cracked. Though drowsy and indifferent, he could yet answer questions, and when

Digitized by Google

moved gave sign of pain in the right chest. There was no tenderness, however, at this place, and no bruising anywhere. When left undisturbed the breathing became slightly stertorous. On physical examination, a patch of impaired resonance was made out below the right scapula, and here the breathing was faint and the bronchial and the vocal fremitus exaggerated. There were rhonchal and sibilant sounds generally throughout the chest, but nowhere crepitation. From such physical and general signs it was concluded that the child had pneumonia in an early stage; but so grave was the prostration and so enduring, notwithstanding free stimulation, as to suggest that there must be something more, as yet unseen, which would be presently revealed. The history obtained, partly from the patient and partly from his mother, an inaccurate, unintelligent woman, was to the following effect:—On the day before admission the boy went to school as usual. Between three and four in the afternoon he came home complaining that while on his way to meet his father, a big boy who happened to be passing had hit him a severe blow with his fist on the right side of the chest. He walked home with difficulty, perhaps a mile, feeling the pain, which movement seemed to aggravate. He had also headache and a sensation of nausea, and it was observed that he would restrain cough owing to the pain it gave him. On reaching home he rapidly grew worse, and, after a restless and feverish night, was brought to the hospital early next day in the condition already described. On a rough calculation some fourteen hours may have elapsed between the time of the blow and the time of admission, but so far as could be gathered only a very short interval between the assault and the appearance of serious symptoms. The apparent origin of the symptoms was sufficiently remarkable—especially, as will be presently seen, when these had fully developed—to make strict inquiry desirable as to the child's previous health; and accordingly, Dr. Thomson, by dint of much questioning, succeeded in eliciting from the mother, on her second visit, some important additions to her original statement. These were to the effect that the boy had "shivered a little two days before the blow"; that he had complained of his throat; and that the mother, who was far from being an anxious observer, had noticed that he "looked ill," and told him to remain at home; and, finally, that on Jan. 5th, three days before the blow, he had been out in the snow all day and got wet through. The after-progress and termination of the case may be dismissed in a few words. The day after admission all the characteristic signs of consolidated lung became apparent as regards the upper third of the right side. Prostration continued; the temperature on the third day reaching 104°. Then came a critical fall of six degrees on the fifth day from admission, and along with it all serious symptoms vanished, and a few days later the boy was convalescent. This crisis, it should be observed, corresponded with the sixth day of illness reckoning from the blow, with the eighth reckoning from the shivering, and with the ninth reckoning from the wetting.

Before considering the character of evidence which this case affords, let me glance for a moment at the authorities. Is external violence (short of lung laceration) capable of producing lung inflammation having all the characters of true lobar pneumonia as regards its course, duration, and end? Fully stated, that is the question. Grisolle, an excellent authority on matters of fact of this kind, hesitates; he hardly admits the possibility of such an occurrence, and uses *à priori* arguments against it; yet he quotes examples, as I will mention presently, of pneumonia resulting from heavy lifting. Dr. Frederick Roberts, also a valuable guide, owing to the wonderful discretion and impartiality with which he brings together the opinions of various authors, places "injury to the chest" among "the exciting causes" of pneumonia[1]. Dr. Bristowe speaks of "the direct action of mechanical irritation," but does not appear to include in this expression external injury.[2] Dr. Wilson Fox, in his well known Treatise,[3] says "injuries and blows to the chest are occasionally followed by pneumonia"; yet he admits that "the mechanism of such cases is obscure," and the single example which he supplies from his own experience is, as he himself seems to imply, far from conclusive. Of earlier authorities, Sir Thomas Watson dismisses the causes of pneumonia in precisely six lines,[4] and in none of the six does he mention injury. Going further back still, we come to foot-note references copied from author to author, and to which time and tradition have given a sanctity seldom invaded by any close inspection. Amongst these is a case quoted by Andral,[5] where the writer himself remarks that the almost complete absence of fever on the fifth day after the accident (a fall from a height) would have negatived the theory of pneumonia were it not for the sputum and the crepitant râle. Modern criticism might not irreverently suggest that at the time these words were written the new-born authority of physical signs was becoming too absolute, while an impartial reading of Andral's description leaves the impression, not that pneumonia was excited immediately by the fall, but that there was an interval of five or six days, and then a true pneumonia with crisis ("amelioration étonnante," in Andral's words, which even his treatment could not always suppress) on the fifth day. So far as authority goes, therefore, we shall violate no canon in regarding this question as an open one. The existing diversity of opinion was exhibited in a very practical way a few years ago in the course of a legal action, in which I was consulted, brought by the relatives of a man who had died of acute lobar pneumonia some two or three weeks after a railway shaking. Compensation was sought at the hands of the company, on the ground that the accident had directly contributed to the man's death; and the medical evidence appealed to on the occasion was described by sober observers as "conflicting."

The case we are now concerned with would seem, at first sight at all events, to give an affirmative answer to the question—Can injury cause pneumonia? After some search, indeed, I am unable to find another so explicit. At the time of the blow the boy was without complaint and walking the streets. It gives him violent pain and he gets home with difficulty. The general symptoms of pneumonia—dyspnœa, fever, pleural stitch—set in almost immediately, and a few hours later, when first medically examined, the physical signs of that disease are discovered. Here surely is proof, the sort of proof we are accustomed to rely on in such matters—better proof, I would go so far as to say, than is afforded either by Andral or Wilson Fox,—that a blow on the chest is a possible cause of pneumonia. And upon first information, in spite of previous experience and preconceptions, I felt compelled to adopt that view.

But further inquiry gave a somewhat different colour to the case. It was ascertained that four days before the injury the boy got wet through, and that he afterwards shivered and looked ill. Now, pneumonia from exposure to cold and wet is common enough, while pneumonia from a blow is, to say the least, very rare. In this contention of causes, therefore, we must prefer the former, and adopting that hypothesis the case stands thus: Pneumonia had already commenced in this boy's right lung when he was dealt a violent blow just over the seat of it. The effect of this violence, acting upon a deformed and yielding chest, was to add to the already commencing trouble a symptom of its own, general collapse; and as this collapse gradually yields, so the proper physical signs of pneumonia develop, until at length the affection declares itself in typical completeness.

A similar explanation would seem to apply not only to external violence, but also to violent muscular effort on the patient's own part. It applies, I believe, to examples quoted by Dr. Grisolle,[6] where pneumonia was attributed to lifting heavy weights. "A violent pain was immediately felt, and in a few hours symptoms of pneumonia declared themselves." Now, if it be difficult to conceive of severe accidents (laceration of lung being put out of the question) producing pneumonia, still more is it difficult to conceive that lifting a burden might have that result. But it is quite easy to suppose that sudden exertion of this sort might *discover* pneumonia. Such extra demand upon the muscular strength, and such extra inspiratory effort as heavy lifting demands, would be exactly calculated to find out a pneumonia which as yet, while the patient was at rest, had given little notice. In like manner other acute affections are sometimes brought to light by means of accidents which could have no possible share in starting them. I remember a sweep carrying forth his bag of soot one morning and falling heavily under its weight. He was brought to hospital in serious collapse, and found to be in the second week of enteric fever, of which he died.

But while it may be doubted whether either external violence, short of lung laceration, or sudden exertion, ever directly excites pneumonia, there is ground for the belief that both one and the other may give occasion for it. For there is a form of the disease of which the predisposing cause—sometimes so far as seems the sole cause—is deterioration of vital energy, a condition to which at present we can apply no more precise expression. Whatever lowers vitality invites pneumonia. In virtue of that principle, severe bodily injury, as well as over-fatigue or alcoholic excess or destitution, or even mental anxiety, may weaken the power of resisting the disease and make its invasions the easier. Pneumonia of this origin needs the more to be recognised, inasmuch as it is a grave and often fatal disorder with quite a different outlook from the pneumonia of exposure. To such category would belong, in my belief, the case just quoted from Andral, possibly also the case of the railway passenger, and other examples which I might quote from my own experience, where individuals debilitated by some injury, but apparently on their way to recovery, die quite unexpectedly by the intervention of a pneumonia of such limited area as to seem at first a mere trifle.[7] Considerations of this sort make us properly cautious in accepting injury or overstrain as efficient causes of pneumonia. Granting that individuals may be up and about in every stage of that disease,[8] granting also that the early symptoms of pneumonia—dyspnœa, pain on deep inspiration, and general muscular weakness—are precisely those which extra exertion or a blow directed against the chest or diaphragm would call into activity and prominence, and it is inevitable amongst a hardworking and boisterous race that accidents of this sort should from time to time call attention to the disease, and appear in the light of causes of the symptoms which they precede.

There is a further question, which I have here expressly excluded, in regard to injuries causing actual laceration of lung tissue, with or without rib fracture. Can such laceration set up true lobar pneumonia? I have no personal knowledge of such an occurrence. But my friend and colleague, Dr. Barlow, has been good enough to tell me of a case of his own which is possibly of that sort. A young stonemason had a heavy stone slab fall on his chest, knocking him down with a very severe blow, yet without fracture of ribs. "He was taken home, and within a day or two developed a typical apex pneumonia. This resolved, but after resolution there was a curious hectic temperature, a condition lasting a considerable time, the morning temperature being normal and the patient meanwhile feeling well and ultimately recovering perfectly," Dr. Barlow adds, "At the time I did not think much of the immediately antecedent injury, but I remember the fact very definitely." Even here it cannot be said for certain that the apex pneumonia was not an intercurrent affection due to the nervous shock of the injury. The facts might be taken in that sense by any reader with predilections of his own in reference to efficient causes of pneumonia. It is indeed the prevalence of predilection on one side or the other which makes the need for further investigation at the hands of independent observers possessed of the rare ability to keep their facts and their theories in separate compartments.

The sum of my contention comes to this. Pneumonia does undoubtedly sometimes follow injury, whether to the chest or elsewhere. In some instances the disease is not really caused by the injury, but only brought to light through its agency; in others it is its indirect consequence—due, that is to say, not to any immediate harm done to the lung, but to nervous shock which, whether it arise from injury or over-fatigue or any other cause, produces a condition of the system favourable to the development of pneumonia. Shall we say, then, that bodily injury is a predisposing but not an exciting cause of pneumonia? It may be so. But as a matter of fact, and notwithstanding that in a country like ours there is generally "weather" to appeal to, the exciting cause often escapes us. That cause, which we call in scholastic phrase "predisposing," be it injury or sewer-gas poisoning, or alcoholic excess, is all that we see. To us it is the *sole* cause. And so it may seem that I demolish the very distinction I have been insisting on. Not so. The distinction is a very real and tangible one, and it is intimately connected with the pathology of pneumonia. For if the relationship of cause and effect be of the nature I have tried to indicate, not only do we bring bodily injury, regarded as a source of pneumonia, within the compass of a large class of causes all acting through the nervous system, but, further, we go far to establish the fact that this pulmonary affection, the true lobar pneumonia of definite duration and orderly sequence of symptoms, is not a lung inflammation merely, but the local expression of a wider, and often of a nervous, disorder.

[7] See British Medical Journal, 1879, vol. i., p. 100.

[8] The number of instances in London alone where people are found in the streets dead or dying of pneumonia in an advanced stage, yet which has never been suspected, is not small. Hospital practice, though it gets a share of these cases, does not adequately represent their frequency. For that we must go to Poor-law infirmaries and coroners' inquests. And not only is this true of what is absurdly called "latent pneumonia," it is true of the acute disease as well, as the following example shows. A working man of middle age, well proportioned and developed as to his frame and muscles, who had been feeling out of sorts for some days, was yet able to take active part in a meeting for political discussion ending with whiskey-and-water. On his way home he met with a fatal accident, falling headlong down some stone steps and fracturing his skull. Post mortem, part of his right lung was found to be solid, and on section and microscopic examination it proved to be a specimen of typical benevolent pneumonia, probably in course of resolution.

HYDROPHOBIA AND THE TREATMENT OF BITES OF RABID ANIMALS BY SUCTION.

BY SURGEON-MAJOR R. PRINGLE, M.D.,
LATE OF THE SANITARY DEPARTMENT, H.M.'S. BENGAL ARMY.

THE treatment now being carried on in Paris for hydrophobia in the stage of incubation, or, to write more correctly, the treatment of conditions which may possibly develop into hydrophobia unless successfully checked by a specific line of treatment, is most deservedly attracting the greatest attention, not only on the Continent, but in this country also; and if continued precautions are not taken to stamp out, or at all events to limit, the disease, by curtailing the means of disseminating it, the subject of this treatment, in the not very distant future, will call for some separate action on the part of the British Government for cases of hydrophobia in the British Isles. Hydrophobia is still in our midst, and only waits the means of propagation, lately supplied in the "plague of dogs," to enable it to burst into another epidemic. On March 19th the stringent police regulations regarding the muzzling and control of dogs expired, and, though these have been renewed in a less stringent manner, yet, as no steps have been taken as regards dog licences to limit if possible the increase of "uncared-for dogs," in a short time the numbers reduced by passage through the "lethal chamber" will soon be made up, and we shall then have again to face conditions peculiarly favourable to the rapid and extensive development of rabies. I yield to none in my fondness for dogs, but the question is *now* not one of likes and dislikes but of public health, and the statistics of bites inflicted by animals supposed to be rabid, if we may judge by those connected with M. Pasteur's experiments, exhibit a prevalence of rabies which appears to call for special action, and, as I believe, demands in the interests of the public health a continuance of the present police regulations on the subject.

Acting on the advice of friends, I have been induced to condense the remarks I made at the meeting held in the Sanitary Institute in London last month, when Professor Horsley read his paper on Hydrophobia. On this occasion I took up the subject of treatment by suction in the case of bites inflicted by rabid animals, as opposed to the ordinary method of applying caustic, or even the actual cautery; and in bringing the following to the notice of the public through the columns of THE LANCET, I do so in the earnest hope that that which was so successful in my own case and in those I shall give hereafter may prove equally so in others. It is sad to think that the present means employed to destroy the virus of hydrophobia seem to be so utterly useless, that to be bitten by a mad dog *now* means a certain looking forward to the most distressing and painful of deaths. In gratitude, therefore, for my own escape, and I repeat in the earnest hope of being able to impart to others the sense of security, or rather immunity, which I realised in an epidemic of hydrophobia, even when having to attend cases of the disease (and this ere the six months had passed since I had been bitten by an undoubtedly mad dog), I enter into the details of the treatment in question, and shall endeavour to do so in a manner which will enable

Digitized by Google

all to practise it, with, I doubt not, the same success which attended my own case.

The other day several people were bitten by a mad dog at Peckham, and more would have been similarly injured had not a brave workman, *pro bona publico*, courageously seized the dog and despatched it, though not before it had bitten him in thirteen places! During the year 1885 I collected the newspaper notices (of which several were inquests) of every case of rabies which has occurred in and around London, and an analysis of these discloses some remarkable data regarding the primary treatment of the bites, and the apparent utter futility of the means employed, I might say in nearly every case almost immediately after the bite was inflicted, to prevent fatal absorption of the poison into the system; and perhaps the saddest feature in these melancholy records of suffering is the fact that, judging by analogy, had the treatment I adopted in my own and the other cases, given in detail hereafter, been carried out, some, if not all, of the sufferers might have escaped the most painful disease to suffer from, and the saddest to witness. In every case except one, that which occurred at Blackheath, and proved fatal with the most distressing symptoms, either caustic or the actual cautery seems to have been used, and we are informed that the wounds healed without at the time any unfavourable symptoms, and yet *in every one of these cases rabies followed and proved fatal.* Another point is worthy of note: in one case in London four persons were bitten by the same dog, and the period of incubation in each case was different, as the record of the fourth closes with—"This is the last of the four persons bitten by the same dog, and all have died of hydrophobia." This variety in the period of incubation is an important point for M. Pasteur to note, as it would tend to the conclusion that the period of incubation is regulated by individual circumstances and conditions in a manner and to an extent not noticeable in any other disease that I know of, the period varying in my own observations from three weeks to six months. There are other important points to which I might draw attention, observable in the previous histories of the dogs affected, which are carefully given in some of the cases, but it would require too much space to allude to them here. The chief objects I have in writing are—(1) to point out the treatment which has been eminently successful in my own practice after bites inflicted by cases of unquestionable rabies in a man, a dog, and a jackal, and particularly in the case bitten by the jackal, which seemed to be a perfectly hopeless one; and (2) to advance an opinion as to the probable cause of the present extraordinary prevalence of rabies, which would seem to be almost epidemic, and the best means of stamping it out. The pattern cases which I will take to illustrate my treatment occurred in India, and were as follows. The first, that by a dog, was my own case; the second, that by a man, happened in the person of one of my native medical subordinates; and the third, that by a jackal, was the case of a native gardener.

In 1860, when in medical charge of the station of Cuttack, in Bengal, while sitting at breakfast, and now and then giving my little dogs, which were house dogs, something to eat, a little English terrier suddenly dashed across the room from one of the corners and seized my hand, putting a tooth nearly through one of my fingers, and having done this rushed out of the room. This little dog was the favourite of all, and I at once concluded that it must be mad to have done what it did, and, taking my knife out of my pocket, laid my finger open where the tooth had entered, and then when the blood flowed sucked the wound and spat out the blood. I also applied a ligature to the base of the finger and got some tepid water, and putting my hand into it made it bleed freely and continuously, and then, when it had, as I thought, bled sufficiently, bound up the wound. I did not kill the dog, but had it caught by means of a light bamboo suddenly and carefully dropped over its back, and, slipping a collar (with two light but strong chains attached) over its neck, safely secured it, as I was naturally anxious for my own satisfaction if possible to prove the dog was not mad. All was in vain; I kept the animal alive for three days by dipping a sponge in strong soup and then presenting it to the dog, who seized it, thus making him unintentionally swallow the amount which he squeezed out of the sponge by the bite. Now, in this case there could not be a doubt that the dog was mad when it bit me, though, of course, it may be urged that perhaps there was not enough poisoned saliva to infect me, and every case of recovery is open to this question. But judging from the appearance of the dog when caught, I am satisfied that the promptness and thoroughness with which I extracted the poison was the means of saving my life.

The second case, that of the chief native medical subordinate attached to the Station Hospital at Cuttack, occurred some five or six weeks after I was bitten, and, being the medical officer in charge of that hospital, I had an opportunity of watching the case throughout. A poor native suffering from hydrophobia was here admitted, and his agonies were such that I ordered a sedative to be given. The sight of the fluid brought on a violent paroxysm of spasm, and, with a shriek more like the yell of the animal that had bitten him (a jackal), he seized the subordinate by the back of the hand with his teeth, though he quickly let it go, and no time had to be lost in treating the subordinate, who, as was to be expected, was in the greatest alarm. I had the hand at once washed with tepid water, and a ligature applied round the wrist. I then with a knife made all the portions of injured skin bleed freely, and after seeing that the subordinate had no injured surface on the lips or mouth, induced him to suck the wound, which he did, and subsequently I applied a cupping-glass, and when I felt sure all the poisoned saliva had been removed, I dressed the wound in the usual manner, and, as in my own case, it healed up rapidly, and was followed by no bad consequences whatever. When we remember how very trifling a scratch will suffice to satisfactorily admit vaccine lymph, if active, into the system, we cannot be too careful in our search for the marks of dogs' teeth. Till death ended the sufferings of the patient in the hospital, he had to be held by the knot of hair on his head usually worn by natives of Orissa, as involuntarily, apparently, he tried to bite, with the view, I suppose, of preventing fluids being given to him, as he knew the suffering that followed the attempt to swallow them. In this case there could be no possible doubt about the quantity of poisonous saliva present when the bite was inflicted, as it was trickling from the poor sufferer's mouth, and yet the treatment effectually prevented any of the virus finding its way into the system of the subordinate.

The third case was the most serious of all, and occurred while I was encamped in the Government Botanical Gardens at Saharupur. The man was raking under a bush, when a jackal rushed at him and seized him by the cheek, and, inflicting a fearful wound, ran off into the gardens. The cry of "mad jackal" was raised, and the gardeners soon finished him, as he had apparently laid down under the bush to die when disturbed by the rake, and was so weakened that he was soon run down and killed. When I saw the animal there could be no doubt of this being a case of hydrophobia in the last stage, and when the man was bitten the poisoned saliva must have been in large quantities on the animal's mouth and lips. My tents were a hundred yards distant, and the man was brought to me at once. The wound had a dreadful appearance, and it seemed hopeless to think of removing all the virus. There was, however, only one bite, which included almost the entire cheek. I first of all washed the cheek and wound with tepid water, and then with a knife from my pocket-case made the parts bleed freely wherever the teeth had entered, and by means of a tumbler and a little spirits of wine extemporised a cupping-glass. There was, however, a spot where this mode of extraction could not be applied, and I felt nothing but the mouth could extract the poison here. Immediately the man was brought to my tent and I had seen him, I asked if he had any relatives in the gardens, and on being told he had a brother I sent for him at once. When he came, after examining his mouth and lips to see if they were free from conditions likely to favour absorption of the poison, I pointed out to him how he might hope to save his brother's life—viz., by sucking out the poison in the part where I could not apply the extemporised cupping-glass. He at once put his mouth to the wound and sucked it freely. When I thought he had removed all the poison, I dressed the wound in the usual way, and it healed quickly. As a precaution after each suction of the wound and spitting out of the blood, I made the man thoroughly rinse his mouth with tepid water. I heard of both these men years after, and was told they neither of them ever suffered in the least, either from the bite or the suction of the wound. In this case I used neither caustic nor the cautery, as I felt to be effectually applied they would almost certainly lead to the sloughing of the cheek. The result of the suction proved that it was most successful and simple,

Digitized by Google

while in every case this mode of treatment facilitated and expedited the healing action in the injured, it may be lacerated, parts. I dwell at length on this case, as it is a characteristic one as regards the treatment I recommend, and undoubtedly seemed a peculiarly hopeless one. I can only add, therefore, that none need despair after the recovery of this case and the harmlessness of the operation of suction. Without doubt it is always better for the person bitten to suck the wound himself; when this is impossible, as in the case of the gardener, then the act of suction can be safely done by others, if the precautions taken in the case of the gardener's brother are carefully carried out.

During my thirty years' service in India, being very fond of dogs, I had not only a considerable number, but also a great variety, and among them only two cases of hydrophobia occurred: one, the case of the terrier which bit me, and the other that of a well-bred spaniel, which I used for pheasant shooting in the Himalayas. The case of the former exhibits the treatment I recommend, and that of the latter the mode of preventing the disease spreading. These two dogs illustrate also the very opposite symptoms as regards their behaviour to their master. The terrier, my pet dog, without any cause or warning other than sulking for a little time, rushed at me and bit me; the spaniel, my sporting companion, passed me on the road, as if it wished to avoid me. I at once felt something must be wrong with the dog, and on my return home the servants told me it was missing. On looking for it near the house, I saw it lying in the shade of a bush, gasping, in a condition of fully developed rabies, and, getting a gun, I shot it at once, before it had started on its mad race and bitten, and thus infected, either man or beast.

Now I would close with a word or two regarding what seems to me the cause of the present epidemic of rabies and the mode of stamping it out. Though nothing but the virus of rabies can produce rabies, yet when segregation favours the spread of the disease, as is the case now, an epidemic quickly results. My Indian experience has satisfied me that if the subjects likely to be affected are limited, the tendency of the disease is to die out, otherwise rabies would be an alarmingly common disease in that country, whereas it is, everything considered, a rare disease. Rabies, without doubt, is a disease due to a special virus, and not to conditions of living or food, otherwise I should have seen numbers of cases of the disease among the dogs and jackals at Juggernauth, where, at certain periods of the year, the food of these animals used to be human corpses, generally the victims of cholera, and little else, and yet among these dogs and jackals in their natural state I never saw a single case of the disease in four years. Thus it will be possible to stamp out the disease, not by removal of the conditions credited (?) with the production of the disease (as if they exist they are unknown further than the insertion of the virus), but by the reduction of the causes which propagate it, and which have lately increased to an extent which would have been incredible had not the results of the late police action told in unmistakable terms what a "plague of dogs" we have been suffering from. One case of rabies till very lately had the power of propagating the disease to an extent which was impossible thirty or forty years ago. Let us, therefore, aim at reducing the number of uncared-for dogs to be met with by a dog suffering from rabies, and we shall then reduce the cases of the disease, till the last mad dog is put an end to, before it has spread the contagion; but this can never be the case with such numbers of uncared-for dogs about. The owner of a dog exhibiting suspicious symptoms should be obliged to place it under supervision, or be answerable for it, so that if rabies is developed, while under this supervision the dog may be destroyed and the possibility of that characteristic symptom of hydrophobia, the mad-dog race, which is the most fertile source of the dissemination of the contagion, effectually prevented.

Blackheath, S.E.

A FEW days ago a beautiful obelisk of red granite, erected by a few friends to the memory of the late Dr. Alexander Hogg, of Workington, in the new cemetery of that town, was unveiled with appropriate ceremony. Dr. Hogg was medical officer of health for the town, and during his short but successful practice of four years and a half endeared himself to all. He died on Nov. 2nd, 1883, while on a visit to his father's house, Larbert, Stirlingshire, at the early age of twenty-six years.

A CASE OF DELIRIUM TREMENS CAUSED BY CHEWING TEA.

BY W. B. SLAYTER, M.D., L.R.C.P. LOND., M.R.C.S. ENG.,
LATE CONSULTING SURGEON, PROVINCIAL AND CITY HOSPITAL, HALIFAX, NOVA SCOTIA.

ON November 10th, 1879, I was summoned by a lady to see her female servant. The girl complained of sleeplessness, nervousness, and repeated twitchings of the muscles of the face and extremities, which would continue for several minutes at a time. These symptoms had been present for several months previously. Her mistress informed me that the girl had been acting strangely for several days. She was wandering in her mind at times, and imagined people and evil spirits were about her seeking to do her harm. She had not slept for several nights, and on one or two occasions had been found at night wandering about the house. Pulse 96 and small; tongue dry and brown; eyes suffused; irregular action of the heart-weight at præcordia; sallow complexion. A dose of bromide of potassium and hydrate of chloral gave her a good rest for the night, and next morning she was sent home to her mother.

At 4.30 A.M. on the 13th I was again summoned to see her. Some men had found her walking about one of the wharves of our city, in the neighbourhood of her mother's house. They tried to persuade her to go home, but she broke away from them and endeavoured to jump off the end of the wharf, when she was caught and taken to her home. I found her with a pulse of 110°, a very dry and brown tongue, suffused eyes, no marked increase of temperature, violent delirium, and tremulous hands and arms—in short, the well-marked symptoms of delirium tremens. Her mother informed me that she had complained of a good deal of pain in the abdomen, and on examination I found a smooth, quite hard tumour in the right iliac region, half as large again as an ordinary orange. Owing to the violent delirium I was unable to find out whether it was tender to the touch or not. A hypodermic injection of morphia somewhat relieved the nervous symptoms. A brisk cathartic brought away a mass of hardened fæces, followed by a large quantity of a thickish tarry-looking excreta, which seemed to be made up of tea-leaves in different stages of maceration, quite a large proportion, probably a third, being tea-leaves quite unchanged in appearance or colour. Bromide of potassium and chloral in a few days quieted the nerve-centres; good nursing, proper diet, and tonics soon restored the patient to her usual health. After the action of the cathartic I found the abdominal swelling somewhat lessened in size, but it was not until several doses at intervals had been administered that the tumour entirely disappeared. After each dose a quantity of tea-leaves were expelled. In about three weeks the evacuations were normal in appearance, and her general health was fairly restored.

I had lost sight of this patient until October last, when I was once more summoned to see her. It is not necessary to again enter on a history of the case. The same well-marked symptoms of delirium tremens were present; there was no tumour to be found, but the evacuations contained a plentiful supply of tea-leaves. The same course of treatment soon restored her to health, and I trust a longer continuance of tonics and building-up treatment may succeed in preventing a recurrence of the symptoms. The patient informed me that when about seventeen years of age she went to one of the New England towns to work in a factory, and there contracted the habit of chewing tea—a habit, she stated, quite common amongst the factory girls. She thought she chewed on an average about half a pound of tea daily, and some days more. It made her feel better able to work. Of course, as to quantity her estimate may not be depended on. She had never been addicted to alcoholism, and ascribed her attacks solely to the tea-chewing. She tried to give it up, but felt so nervous and fidgety as to be compelled to return to the old habit. This second attack caused me to copy from my case-book the notes taken at the time. The only points of importance are the *cause* and the *repeated and continuous muscular twitchings*. Of course most physicians have met with many cases of great nervousness and fidgetiness occasioned by excessive tea-drinking, but I cannot find any record in any of the works on medicine or materia medica within my reach of such severe symptoms being induced by tea-chewing. Ringer tells us that "the

Digitized by Google

Physiological Committee presided over by the late Dr. Hughes Bennett concluded that the *motor nerves are unaffected.*" The long-continued repeated muscular twitchings would seem to contradict this portion of the committee's report.

ROTHELN: A POINT OF DIAGNOSIS.

By JAMES GREY GLOVER, M.D.

THE extreme infectiousness, notwithstanding the comparative harmlessness, of German measles makes it very desirable to find early indications of its presence. I have been struck lately in two or three cases with the fact that the earliest symptom to excite the notice of the patient has been a swollen gland in the neck at the back of the sterno-mastoid muscle. One young lady lately consulted me about such a gland of a considerable size, and without any obvious explanation in its neighbourhood. Four days later the rash of Rotheln appeared and explained the mystery, and the single gland had become the usual chain on both sides of the neck. When the disease is prevalent, or already exists in a family, and a swollen cervical gland in a young person appears without obvious reason, it may be suspected that the disease is already in the system. The occurrence of cervical glandular enlargements is of course one of the commonest and most interesting notes of this least pyrexial of the eruptive diseases, and the early appearance of the symptom coincidently with the rash, or even a day before, as Dr. Goodhart describes in one case, is also known. But its appearance four or five days before the eruption seems worth noting for diagnostic purposes.

SEAMEN'S HOSPITAL, GREENWICH.

ULCERATIVE ENDOCARDITIS; ANOMALOUS SKIN ERUPTION; INTESTINAL ULCERATION; DEATH; NECROPSY.

(Under the care of Dr. CURNOW.)

DURING the last few months, especially since the delivery at the Royal College of Physicians of the lectures on Malignant Endocarditis, we have published several cases of ulcerative endocarditis, but none of them have presented the unusual features of the following case, which is well worthy of record. The difficulty of diagnosing the exact cause of the disease in the absence of evidence of cardiac mischief was insuperable. We are indebted for the following notes to Mr. E. H. Booth, M.B., house-physician.

James K——, aged forty-five, was admitted on March 12th, 1886. On examination his condition was found to be as follows: He was lying deep down in the bed; face flushed; pupils dilated; excited and delirious—so much so that all attempts to procure a history failed. His tongue was rather enlarged, red, dry, and glazed. Temperature 103·5°; pulse 120, very weak and fluttering. Decided œdema of feet and ankle; effusion in both knee-joints; well-marked purpuric rash on both legs, mostly on the inner sides; purpuric blotches on the inner side of the thighs, and a few purpuric spots on the front of the thighs. There were erythematous patches with petechiæ over the parts exposed to pressure—i.e., over both hips, shoulders, and elbows. There were a few livid red patches over some of the joints of the hands. A few petechiæ were scattered over the surface of the abdomen and chest, also a few spots, looking very much like typhoid spots in character. His abdomen was distended and tumid; resonant all over. During the first night he was in the hospital he passed a very loose stool, greenish, and tinged also with a little blood. Heart listened to very carefully; beating rapidly, and sounds very feeble; no bruit to be heard. Chest resonant all over; moist sounds at both bases; no other physical signs. Urine very acid; sp. gr. 1026; loaded with albumen; deposit of urates; no blood or casts.

It was thought that the patient might be suffering either from pyæmia or severe typhoid. He was given five grains of quinine every four hours, and twelve ounces of brandy were ordered. His temperature, taken every two hours, kept between 103° and 104°, in spite of wet packing. He gradually sank, and died on the night of the 13th.

Post-mortem examination.—A good deal of cadaveric lividity. Rigor mortis marked. Abdomen opened. The small intestines were rather distended; pale, but presenting at intervals patches of congestion pointing to ulceration. The intestines were opened up, and there were discovered about fifteen to twenty ulcers; the majority of these were round, with ragged edges; each ulcer was surrounded with a large patch of congestion; at one or two places the ulcers were longitudinal in direction, and occupied Peyer's patches. At a few other places were patches of congestion, and in the centre of each patch a small grey hard nodule about the size of a pin's head, and not unlike tubercle in appearance. Most of the ulcers were in the lower part of the ileum, but one or two small ulcers existed near the duodenum. Heart: Old pericarditis, there being dense adhesions over most of its surface; the pericardial cavity remaining contained a small quantity of semi-purulent matter; heart not enlarged; right side normal; aortic valves thickened, especially towards the edges; mitral valve thickened; along the edges was a continuous fringe of fine granulation and ulceration; at one spot the ulcer was about half the size of a threepenny piece. Kidneys enlarged, pale; capsules not adherent; all over the surface were seen a number of small yellow spots, each surrounded by a halo of congestion, each spot being a minute abscess; on section it was pale and dotted all over with minute abscesses and points of congestion. Spleen much enlarged; about three times the normal size; very soft and congested; no infarcts to be distinguished. Lungs very œdematous and congested; almost black with congestion towards bases; no infarcts to be distinguished.

The case is of peculiar interest from the difficulty in arriving at a diagnosis, the anomalous character of the eruption, and the numerous ulcers in the intestines from infarcts carried from the diseased valves. It is most uncommon to find so many intestinal ulcers from this cause.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY.

CASE OF ERYTHEMA NODOSUM; REMARKS.

(Under the care of Dr. FRANCIS HAWKINS.)

MARY D——, aged thirty-five, married (no children), tailoress, born in London, was admitted on Aug. 30th, 1885, complaining of sore-throat, thirst, anorexia, and constipation. She had been ill about one day. Her father was a Pole. He died from abscess of the lung. Her mother, a Frenchwoman, died in an asylum. She has four sisters. Two are quite well and have never been ill. One older than herself had an illness (erythema nodosum) similar to her own four years ago. The other sister, also older than herself, had a fit four years ago; the medical attendant pronounced it epilepsy. She has had frequent repetitions of the fits, and last August was placed in an asylum, where she still remains. There is one brother quite well. There is no history of rheumatism ever having occurred in the family. Her home is comfortable. She works at her calling away from home. Eleven years ago (at the age of twenty-four) the patient had pains and swelling in the ankle-joints, and a few red painful spots on her legs. Her medical attendant informed her she had rheumatic fever, but she was up and about the whole time. From this attack she entirely recovered, and remained perfectly well until four years ago (at the age of thirty-one), when she felt weak and had sore-throat, for which she went as an out-patient to King's College Hospital. Three days after attending there she felt pains in her joints, and some spots came out on her legs, similar to the spots which came out seven years previously This time the spots came out on the arms as well as on the legs. (It was about this time that her sister also had pains in her joints and spots on her legs similar to those on the patient; her sister has never had a second attack.) From this she soon recovered, and continued quite well until the 30th of August, 1885, when

Digitized by Google

she was admitted to the dispensary complaining of sore-throat, &c. She is a stout woman, with a full, red face, and dark hair.

The patient was treated for ordinary sore-throat, and in three days returned complaining of having spots on her legs. At this time she had one spot, red, prominent, and very painful when touched, situated over the right tibia; and one over the left tibia, similar in character, but smaller in size. On Sept. 2nd she complained of much pain from these spots, and, being unable to walk, took to her bed. On the right leg was a swelling about the size of a hen's egg over the anterior border of the tibia, elevated, red in the centre, resembling a bruise at the circumference, and very painful to the touch. On the left leg was a similar but smaller swelling over the tibia and near the ankle. Smaller spots, but of like character, existed over the styloid processes of the right and left ulnar. There was no marked heat or increase of temperature.

Sept. 8th.—Left arm: One spot between the second and third phalanges of the left hand; a few spots on the outside of the arm near the insertion of the deltoid. Right arm: Wrist swollen, and very painful; elbow also swollen; some spots on the arm. Left leg: Bruise-like appearance of spot, as before mentioned; fresh spots on inside of leg and behind the knee. Right leg: Same spot present, and still looking like a bruise.

12th.—Fourteen spots on left arm, mostly on the extensor surface. Spots on leg still present. Right arm: Twenty spots, varying in size from that of a pea to that of a sparrow's egg. Wrist and elbow-joints still somewhat swollen, but less painful.

18th.—The spots all present, presenting a bruise-like appearance.

22nd.—Spots very faint. Patient got up on the 21st. On each occasion of a note being made the temperature was taken, but on no occasion had it risen. Circulatory system: No cardiac murmur perceptible. Urinary system: Examined on first occasion only; urine then clear; no albumen.

Remarks by Dr. HAWKINS.—While there is no history of rheumatism or rheumatic tendency in the family antecedents, we have a marked neurotic history, the mother having died in an asylum, and a sister having epilepsy frequently for four years, and then having to be placed in an asylum; then we have erythema nodosum in another sister; and we have recurrence of the disease in the case under review—the first time when twenty-four years old, the second when thirty-one years old, and the third when thirty-five years old. The former attacks were, I think, beyond doubt erythema nodosum; the patient herself recognised the resemblance between this attack and her former ones, and the resemblance of her disease to that from which her sister suffered four years ago. This case may be said to resemble rheumatic fever in the following points: Thirst, anorexia, constipation, and sleeplessness; the appearance of the spots and swelling of the joints being preceded on two occasions by sore-throat, then pain and swelling of the joints. It differs, however, from rheumatic fever in there being no rise of temperature and no sweating; and there was no cardiac affection left.

MOUNT GAMBIER HOSPITAL, S.A.

ABSCESS OF BRAIN; CYST CONTAINING NECROSED BONE; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. A. WORSLEY POWELL, Assistant Colonial Surgeon and Medical Officer.)

H. V——, a German, aged twenty-six, three years resident in the colonies, was brought to this hospital by the police on the evening of Feb. 18th. Before the police found him it appears he had been lying in a tent for three days unattended and in a semi-comatose state. When reported Dr. Ockley of Penola was sent for and ordered the man to be removed to this institution. Dr. Ockley's notes are as follows:—"H. V——, semi-comatose, with loss of speech. Pupils contracted, with only semi-sensibility. Evidently oppression on brain, probably embolism from some injury or obscure obstruction of the circulation. No opportunity for treatment. Forwarded to Mount Gambier Hospital."

On admission the deceased, aided by a porter, walked to his bed, but he could neither speak nor hear. He seemed in a state of great stupor. Temperature 104·6°. Pupils contracted and insensible. He passed a very restless night, tossing about and moaning continually. There was no paralysis.

Feb. 19th.—At 6 A.M. by signs he asked for his trousers, seemed much better, and drank some milk, the temperature being 104·8°. He sat upright in bed for nearly half an hour but still could neither speak nor hear. Questions were written, but he did not seem to understand them, making no signs in reply. When asking for his trousers he pointed to his legs and then to some trousers belonging to a patient in the next bed. When his trousers were brought he put them on and seemed satisfied. At 7 A.M. he had a slight epileptiform seizure and relapsed into a semi-comatose state. At 4 P.M. he had strong convulsions, vomited a large quantity of watery fluid, and died shortly after midnight.

Necropsy.—Body well nourished. No external marks of injury either on head or trunk. No traces of syphilis. When removing the skull-cap the saw ran through the left parietal bone immediately above the ear, and a large quantity of pus (greenish in colour and of offensive odour) rushed out. The bone here was but a mere shell, and for a space of about one inch in circumference could easily be broken with the finger-nail. The dura mater was very firmly adherent to the bone and could not be separated over a space of about two inches square. The finger, when introduced into the opening whence the pus was coming, passed immediately into a large cavity, the size of a small orange, the cavity leading into the lateral ventricle. About midway, lying loosely in this cavity, a cyst was found. It was hard, black, and resembled in size and shape a small Barcelona nut. It measured an inch and a quarter in diameter. On opening the cyst, the membrane of which was very tough, there were found three small pieces of necrosed bone. The pus and bone were, of course, verified under the microscope. The heart and lungs were quite healthy; the liver was very much congested, and weighed 5½lb.

No history concerning the deceased could be gathered by the police, but on the day following his death a friend who had emigrated with him, and had been his constant companion for some years, was seen by Mr. Powell, who obtained from him the following history: When deceased was fourteen years old he fell from a ladder on to the iron wheel of a barrow, striking his head. He was unconscious for some days, and very ill for over two months. Since then he had had frequent "fits," which left him weak for two or three days. He had had none of these "fits" after coming to the colony until about fourteen months since, so that there was an interval of nearly two years. He suffered greatly from his head, complaining of constant and violent headache. He had frequently taken medical advice for this, but always without relief. He also complained of being severely troubled by cramp. He was a temperate, hard-working man; could do a hard day's work with any man, except for a few days after the "fits." He had been working up till February 13th. He never had any symptoms of paralysis.

Remarks by Mr. POWELL.—I am not aware whether any similar case is recorded. In vol. i. of "Holmes's System of Surgery," third edition, a case is mentioned of a cyst containing pus following diseased temporal bone. In this case there was no disease of the ear, there had never been any discharge from it, and the temporal bone was quite healthy. There was no sign of any scar on the scalp over the injured bone. It seems marvellous that in such a case the man should be able to work and go about with all his faculties unimpaired until a few days before his death.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Littre's Hernia.—Simple Meningitis.

THE last ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President in the chair.

Mr. J. H. MORGAN read a paper on a case of Littre's Hernia. Having described Littre's original cases, he proceeded to relate his case, which was interesting, in addition to its rarity, from the circumstance that no gangrene of the herniated portion of the intestine occurred. The patient was an elderly woman aged sixty-four, who had suffered from constipation for from two to three years, and had also vomited considerably. Some blood was passed per rectum from time to time. Purgatives and enemata were ordered

Digitized by Google

to overcome the constipation, but tenesmus, with the passage of blood and mucus, only resulted from this treatment. Some umbilical pain was complained of. She was admitted into Charing-cross Hospital in a state of exhaustion. There was no local tenderness at any part of the abdomen, and but slight tympanites. A large flaccid protrusion of the vagina containing bowel presented many excoriations on its mucous surface. There seemed to be no reason for regarding the obstruction of the bowels as situated in the vaginal protrusion. Belladonna and opium were ordered. The temperature was 97° and the pulse 92. There was little vomiting, but it was stercoraceous on one occasion. Mr. Morgan performed a limited laparotomy, and the colon was found collapsed, but the patient was not able to bear further operation and died the next day. At the necropsy the lungs were œdematous and the left ventricle of the heart hypertrophied. There was a Littre's hernia, involving but a small portion of the circumference of the small intestine, and protruded a short way into the femoral canal; there was no gangrene of the herniated protrusion. The uterus was greatly atrophied; there was double rheumatic arthritis of the hip-joints. The symptoms as described by Littre were detailed, showing that in this form of hernia the bowels acted regularly; there was seldom hiccough and vomiting, which was never stercoraceous; the herniæ never attain a large size. In Mr. Morgan's case several of the alleged symptoms were wanting, and the case looked more like one of malignant disease of the colon.—Mr. FREDERICK TREVES pointed out that the name of the surgeon was Littre (without an accent), who flourished in 1700. He believed that Littre's first case was really a Meckel's diverticulum, which had become filled with concretions, and contained in a hernial sac. Most of Littre's hernias were of femoral origin, and occurred more frequently in females; it was limited to enterocele, the omentum not being involved, and more common in old than recent hernia. The obstruction of the intestines in strangulated hernia was probably not mechanical, but due to nervous influences. He considered that in Littre's hernia the symptoms were the same, though milder than those of ordinary strangulation. In cases of operation for strangulated hernia, Mr. Treves said that he now generally adopted a method which appeared to him to give the very best results in the way of combating collapse, especially in old people. The stomach was emptied of its feculent contents by means of the stomach-pump, and about a pint of hot water used to wash the organ out thoroughly. In addition to removing collapse, it prevented the vomiting due to the anæsthetic. The injection was made just before the abdominal sutures were inserted.

Dr. W. H. DAY read notes of two cases of Simple Meningitis. The first case was that of a girl aged twelve, who had all the symptoms of tubercular meningitis. The post-mortem examination showed intense congestion of the pia mater, without any tubercles to be detected by the naked eye. Enlargement of the glands of the abdomen was the only other abnormality detected, and this was said not to be tubercular. The second case presented similar difficulties in diagnosis; it was also a girl, aged ten.—Dr. ISAMBARD OWEN asked on what precise anatomical points he had established the diagnosis of meningitis in the first case, which had lasted for fourteen weeks.—Dr. C. H. F. ROUTH testified to the difficulty of diagnosis in the early stage of diseases of children.

ACADEMY OF MEDICINE IN IRELAND.

Duties of Medical Officers of Health.—Muscular Anomaly of Right Upper Extremity.—Nerve-supply of Short Muscles of Thumb.

IN the sub-section of State Medicine, held on Feb. 4th, the PRESIDENT (Dr. Jacob) delivered an address on The Poor-law Medical Charity System of Ireland.

Dr. EDGAR FLINN read a paper on the Duties of Medical Officers of Health in England and Ireland contrasted. He referred to the great disadvantages under which the Irish health officer laboured in the execution of his duties, and deprecated the system of appointing dispensary medical officers as medical officers of health, and the paltry stipends of ten and fifteen pounds a year that they received. There were few medical officers of health who took any great interest in the sanitary condition of their districts, and those who furnished their boards with monthly reports were unheeded, and but scant notice taken of their suggestions. In England, on the contrary, the recognised duty of the urban or rural sanitary authorities was the health of the people; the medical officer of health was obliged to make monthly or fortnightly reports, which were duly discussed, and the officer's suggestions promptly acted upon. The sanitary condition of the towns and villages throughout Ireland showed very plainly to the most careless observer whether the provisions of the Public Health Act were carried out and enforced or not. It was yearly becoming more evident that the Irish Local Government Board would have seriously to consider the question of districts and unions being combined for the better administration of the Public Health Act. In lieu of there being such a plurality of medical officers in each district and union, with a superintendent medical officer of health, there should be one or, at most, two who should be men free from the cares of practice, with special sanitary knowledge, and whose pecuniary interests would not be perpetually at war with a fearless discharge of their duties. This combination of districts had worked very well in England, and it was one of the main reasons why the Public Health Act was so thoroughly and efficiently carried out. The same combination of districts should hold good in Ireland.—The REGISTRAR-GENERAL said he was one of the earliest persons who took an interest in promoting the very service which Dr. Flinn had condemned. One of the reasons for adopting the present system at the passing of the Public Health Acts, 1874-78, was that the English system had worked so badly that it was desirable to try something else in Ireland. The best health officers had to retire consequent on the authorities letting that system go to pieces. The want of independence of Irish medical officers applied equally in England. If the medical officer were not paid a large salary, or had no private practice, he could not be independent; and if in private practice, there was a possibility of some of his patients being on the board. The unions in the west of Ireland could not supply funds to maintain public health officers independent of private practice. There were reasons why the dispensary medical officer should be also the best officer of health. In a large number of infectious cases the dispensary doctor was the medical attendant, and he was accordingly enabled at once to isolate such cases and stop the spread of the disease. Thus the notification of the infectious disease was avoided, and the necessary precaution taken, without the difficulty experienced in cases of compulsory notification by an independent practitioner. Moreover, the dispensary doctor saw many things dangerous to health as he went through his district, and these he remedied at once. Hence the advantage of combining the two offices. Apart from certain difficulties and occasional mistakes, there was in Ireland the best sanitary system of police that existed in the world.—The PRESIDENT said he was in the happy position of concurring with both Dr. Flinn and the Registrar-General. The Irish system deserved many animadversions, while, at the same time, he was sensible of the desirability and importance of having the medical officer of health one and the same with the dispensary medical officer. In Ireland there was a corps of 860 officers, who went every day in the week into places where there was most likelihood of the existence of dangers to health. They were their own informants, and therefore he preferred a widely scattered service, such as the Irish dispensary service, to a concentrated, centralised service, such as Dr. Flinn advocated. But the Irish medical officers were badly paid, and worked under discouragement.—Dr. FLINN, in reply, said he bowed to what Dr. Grimshaw had said, but, at the same time, repeated, from what he had seen here and from his experience in England, that he could not forego what he had stated in his paper. In England the combination of districts had been a success. The districts were well managed, and there never was any difficulty.

In the sub-section of Anatomy and Physiology, held on Feb. 11th, Dr. BROOKS exhibited the Pisi-uncinatus Muscle, as one of exceptional rarity, which he had discovered in dissecting a hand.

The Chairman (Dr. HEUSTON) made a communication on a Muscular Anomaly of the Right Upper Extremity, which consisted of two sets of muscular fibres, the lower of which passed from the latissimus dorsi across the first stage of the brachial artery, while the upper, taking origin from the cartilages of the sixth and seventh ribs, crossed the axilla

Digitized by Google

and third stage of the axillary artery, to be attached with the former set of fibres into a broad triangular tendon, the external border of which passed over the biceps and pectoralis major to be attached into the deltoid, while from its inferior angle a tendon passed to the internal condyle of the humerus.—Dr. FRAZER asked what was the exact relation of the upper muscle as a homologue to the third pectoral found in birds of powerful flight?—Dr. BROOKS considered the chondro-epitrochlearis as a very rare muscle. In two or three sessions of hard work he had not met with a single specimen.—The CHAIRMAN, in reply to Dr. Frazer, said none of the fibres bore any relation to the coracoid process.

Dr. BROOKS read a paper on Varieties in the Nerve-supply of the Short Muscles of the Thumb. He said his object was to show that, in a large proportion of cases, the outer head of the flexor brevis pollicis received a nerve-supply from the deep branch of the ulnar nerve, whereas in all the English text-books the outer head was described as being supplied by the median only. Dr. Brooks then alluded to the different ways in which various authors had described the thumb muscles, and quoted the description in the last edition of Quain's "Anatomy," in which the outer or radial head of the flexor brevis is shown to consist of two parts—a larger superficial portion and a fasciculus springing from the deep origin of the muscle. He had invariably found that when one of these portions received a supply from the ulnar, the nerve also extended to the other.—Dr. HENRY KENNEDY said one important aspect of the subject was how far nerve-supply and muscular change accounted for the extraordinary difference that existed in different individuals as regards the use of the hand; for instance, in painting, carving, playing, writing, &c. Again, there was a remarkable difference in the power different people had of facial expression. Thus, Garrick, with the slightest movement, could express the idea he wanted to convey without saying a word. Another important aspect of the subject was that of its bearing on local disease of nerves. Recent investigations indicated that tabes dorsalis, locomotor ataxy, and writers' cramp were not dependent on the spinal cord at all, but on local disease of the nerves themselves.—Dr. FRAZER said their knowledge of animals and of the nerve and arterial supplies was in a transition state. What they had been in the habit of calling anomalies were now referable to the real causes in muscular anatomy as being the representatives of things in other animals, and under other conditions, pointing to the existence of a law.

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of this Society was held on March 5th.

Primary Encephalo-scirrhus of Common Bile-duct.—The PRESIDENT (Dr. Bradbury) read the notes of the case of W. L——, aged fifty-five, married, a laundry-man, admitted on Nov. 5th, 1885. His mother had suffered from rheumatism, and one brother had died of phthisis; there was no former history of new growths. He had served in the army during the Crimea and the Indian mutiny, being invalided home from the latter for virulent ophthalmia, which led to total blindness in both eyes. He had gonorrhœa when in the army, but no syphilis, and drank heavily of both beer and spirits in youth, but not of late. His present illness began with slight cold on September 16th, followed by vomiting and pains in the abdomen. On October 15th jaundice first made its appearance; and from this time the patient began to lose flesh and suffered much from itching of the skin. The heart was found to be normal, and a few râles were heard in the lungs behind. Liver dulness began at the sixth interspace, and extended to the lower border of the rib cartilages in the nipple line; slightly tender on pressure, but no irregularity or swelling detected. Urine 1020, dark-brown colour, acid, no albumen or sugar. The patient continued in much the same condition, colour varying slightly from time to time, with gradual loss of flesh and strength, being at times troubled with diarrhœa, till November 30th, when a small abscess appeared over the right eye; from this time other abscesses appeared, always in the subcutaneous tissues, principally on the thighs and abdomen, but nothing was ever felt over the liver, and the patient gradually sank on February 10th, 1886. The temperature remained normal till the abscesses became general, and then fluctuated from 101° to 103°. The treatment was principally with nitro-hydrochloric acid, taraxacum, and gentian. At the necropsy, the gall-bladder was seen to be much distended and pyriform in shape. The liver was firm, tough, and elastic, not enlarged; there were a few yellowish-white nodules on the surface, in size much the same as tubercular granulations. The gall-bladder was distended with mucus, otherwise healthy. A probe could be passed with ease up the common orifice of the bile and pancreatic duct, and into the common duct, and thence to the portal fissure, but not up the cystic duct or pancreatic duct; the mucous membrane extending for half an inch from the apex of the ampulla seemed quite healthy; immediately above this the mucous membrane was found completely destroyed to the extent of one-third of an inch, and replaced by a somewhat firm stricture with an irregular surface; then the mucous membrane again abruptly commenced, as also the dilatation of the common bile-duct. On the under surface of the right lobe of the liver was found a large abscess firmly adherent to the liver substance, and connected with the pelvis of the kidney by a small fistulous opening. Both kidneys were congested and bile-stained, and scattered through their substance were numerous small yellowish-white bodies, some of the older ones presenting a distinct puriform centre. The spleen was somewhat enlarged and soft, and the pericardium showed a layer of recent coagulated lymph. The bladder contained from two to three ounces of grumous pus, similar to that in the abscess surrounding the right kidney. The microscope showed the stricture to be an encephalo-scirrhous carcinoma, and the nodules in the liver and kidneys small abscesses. The President said it appeared to be a case of primary cancer affecting the common bile-duct, and he was unable to find any case on record. The abscesses appeared to be secondary to the one about the right supra-renal body, but the causation of this one was doubtful.

Primary Malignant Disease of Prostate.—Mr. CARVER showed this specimen, taken, post mortem, from a man aged sixty-six, who was admitted to Addenbrooke's Hospital on November 4th, 1885. He was at this time suffering from frequent painful micturition. The urine contained no blood, pus, phosphates, or albumen, but he complained more particularly of fulness and discomfort after food, with epigastric tenderness and constipation. For the last four or five years the bowels had acted, as a rule, only after aperients. On admission he was rather emaciated. Pulse 54, regular; arteries slightly knotty. Examination per rectum showed the prostate to be enlarged, and on its right side a nodular projection could be felt about the size of a cherry; another of similar size was felt about the situation of the right vesicula seminalis. Fourteen days after admission he had complete retention of urine, relieved by catheter. He then complained of pain in the right hypochondriac region. The liver rapidly enlarged, and the surface was felt to be distinctly nodulated; the abdomen was tympanitic and distended. He died on December 14th, 1885. At the necropsy the prostate was found much enlarged with new growth, the growth bulging into the rectum (which was healthy). Two tumours, each about the size of a small hen's egg, were found adherent on each side to the bladder and rectum and to the pelvic wall, so that on removing the bladder these tumours were cut through. From the outer side of these a chain of secondary tumours and enlarged glands about the size of filberts stretched upwards along the pelvic walls and iliac vessels to the lumbar glands, which were similarly affected. There were a few deposits on the mesentery and many on the parietal peritoneum, especially on the under surface of the diaphragm, and there was much fluid in the peritoneal cavity. There were numerous secondary deposits in the liver, and on the visceral and parietal pleura. Microscopic examination showed the deposits were medullary in character.

Aneurysm of Arch of Aorta.—Mr. MARTEN showed this specimen, from a man aged forty-one, who had had symptoms of an intra-thoracic aneurysm for more than two years. During life a pulsating tumour was detected under the right sterno-clavicular articulation. At the necropsy this was found to be a secondary aneurysm springing from an aneurysmal dilatation of the whole aortic arch. It extended upwards in front of the innominate artery, and contained a firm laminated clot, which projected into the aorta. The upper part of the sternum was eroded by this aneurysm, as were the bodies of the third and fourth dorsal vertebræ. During life surgical interference was proposed with a view to tying the right subclavian and carotid, but it was evident that no benefit would have followed.

Digitized by Google

Occipital Meningocele.—Mr. LAURENCE HUMPHRY showed an example of this affection. The tumour was nearly as large as a child's head, and protruded through an opening in the occipital bone, about an inch in diameter. A vertical section had been made through the head and tumour slightly to one side of the median line. It was a simple meningocele, and contained no brain. Its cavity was continuous with the fourth ventricle and posterior subarachnoid space, and the dura mater lining its walls was thickened in parts, forming bands, but there were no septa or loculi. The *iter a tertio* appeared to be closed, but there was no hydrocephalus. The cranial bones were remarkably thin, the fontanelles and sagittal suture widely open. At the posterior inferior angle of the parietal bone there were two or three spots, where ossification was defective; these were about the size of a split pea and covered by membrane.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on March 5th.

Cardiac Hypertrophy and Kidney Disease.—Dr. CHURTON showed specimens in support of the view that granular kidneys are accompanied by cardiac hypertrophy only when there is also widespread disease of the systemic arteries. The kidneys were in this case markedly contracted and granular; there was little atheroma of the aorta and none of other arteries; weight of heart, 9½ oz. In a case shown by way of contrast the kidneys were normal to the naked eye; stripped perfectly well; there was only slight microscopic change; the entire aorta and the coronaries were very atheromatous; valves of heart competent; the renal trunks were rather stiff and dilated; other arteries were also diseased; weight of heart, 17½ oz. He had notes of several other cases to the same effect.

Asphyxia from an Orange-pip in the Trachea.—Mr. MAYO related a case of the above. The patient, a child aged eight, was brought in a state of rather urgent dyspnœa, with a history of having swallowed a button. Symptoms pointed to the obstruction being in the trachea or left bronchus. Tracheotomy produced a partial relief; inversion was tried without success. The child died from gradual asphyxia about eighteen hours after swallowing the orange-seed, which was found, post mortem, fixed about the middle of the trachea and almost completely occluding it.

Ether Inhaler.—Dr. PURDY showed and described Dr. Blaikie Smith's ether inhaler. In its employment the patient does not rebreathe his expired air. The advantages of safety, simplicity, and economy are claimed for it.

Defective or Scanty Menstruation.—Dr. BRAITHWAITE read a paper on the treatment of some cases of this affection by Dr. Greenhalgh's stem. He spoke of potassium permanganate as useless, and detailed attempts to provoke menstruation in certain cases by the introduction of caustic, and afterwards pieces of cotton coated with pitch and other such "foreign bodies" into the uterus. He had found, however, that the rubber stem invented by Dr. Greenhalgh by far the best method, the only objection to it being that previous dilatation by a tent was necessary.—Mr. MAYO and Mr. TEALE recommended rapid dilatation under ether by means of sounds. The latter had done this in about fifty cases, with only one in which any ill effects had followed. The canal should be dilated up to the size of No. 12, and no harm was produced by a slight laceration of the cervix. There was then a free vent for pent-up secretions. He had seen bad results from using tents.—Dr. FARQUHAR spoke of the uselessness of permanganate and apiol, but had obtained good results from iron and aloes and pilocarpine.—Dr. BRAITHWAITE, in reply, said he had never seen bad results from the use of tents if they were dipped in thymol soap and covered with iodoform before introduction.

Distension of Gall-bladder treated by Aspiration.—Dr. IRVING read a paper on a case of this kind. The patient, a woman of sixty, of previous good health, was suddenly seized with severe epigastric pain, gradually spreading to the right hypochondrium, with tenderness. There was slight jaundice and an area of dulness in the region of the gall-bladder, both of which increased. The icterus then decreased, but the motions remained pale. A syringe inserted into the dull area drew off a light-brown fluid. Three days after there was much bulging apparent, extending over most of the right side, as far as the crest of the ilium. Sixty-two ounces of yellowish-brown, partly viscid fluid were withdrawn by an aspirator, followed by great relief. The fæces still remained pale, but five days after there was a copious evacuation per rectum of fluid similar to that aspirated, and except on one day, on which there was a rigor with pyrexia, the patient made a rapid and uninterrupted recovery. The fluid examined by Dr. Sims Woodhead of Edinburgh contained a sediment consisting mostly of cholesterine and bile pigment.—Mr. MAYO ROBSON preferred the operation of cholecystotomy, in cases of this kind, to aspiration.—Mr. TEALE referred to a case of extreme epigastric pain, with a lump in the position of the gall-bladder, completely relieved by an hypodermic injection of morphia.—Dr. EDDISON thought that the operation of opening the bladder was a severe one, and in acute cases generally unnecessary.—Mr. LAWFORD KNAGGS recommended aspiration as preliminary to operation, as the distension itself might be partly a cause of the obstruction.—Dr. GRIFFITH spoke of the harmlessness of aspiration, and referred to a case of cancer of the pancreas, where the gall-bladder was aspirated three times, the first operation drawing off quite clear fluid; afterwards it was of a green colour.—Dr. BARRS thought that further evidence was needed as to the particular class of case suitable for cholecystotomy, as the operation was not without danger, and there had been no case of death from distension of the gall-bladder.

At a meeting on April 2nd the following subjects were brought forward.

Injuries to Joints.—Mr. MAYO ROBSON read a paper on a series of cases illustrative of the treatment of severe injuries to joints, and referred to the following cases, all of which had been under his care during the past year, and had been treated antiseptically by means of perchloride of mercury solution (1 in 2000) and dry dressings, and in every case a sound movable joint had resulted. (1) Compound comminuted fracture of the patella, with wound of the knee-joint; (2) compound comminuted fracture of the humerus, with wound of the shoulder-joint; (3) compound fracture of the humerus, with wound of the elbow-joint; (4) compound dislocation of the astragalus backwards; (5) suppuration in the knee following injury, treated by incision and drainage; (6) suppurating hæmatoma of the knee-joint in a man aged seventy, treated by incision and drainage. Several of the cases were shown.

Mr. EDWARD ATKINSON showed three patients who had been recently under his care in the Leeds General Infirmary. 1. A man aged thirty-seven, the subject of popliteal aneurysm, in whom ligature of the femoral artery was followed by gangrene of the foot, for which amputation had been performed through the calf by a long posterior flap, while the contents of the sac were still unconsolidated. 2. A boy of fifteen, who had suffered primary amputation of both arms for an accident in which he had fallen in front of some railway waggons with both limbs outstretched across the metals. The left arm had to be amputated through the shoulder-joint, and the right within two inches and a half of the head of the humerus. Both had healed rapidly without a bad symptom. 3. This was a case of enormous left inguinal hernia in a man of fifty-five, who had been admitted with urgent symptoms of strangulation. Taxis had been freely used before admission. The sac was found to be tense and dark-coloured, and on being opened a quantity of dark grumous serum escaped. Nearly, if not quite all, the ileum was in the sac, and at two points the gut was ruptured. The adherent sac was too large to be stripped and removed. The patient was under ether for an hour and three-quarters. He had no general peritonitis afterwards; and though suppuration of the sac retarded his recovery, it resulted in contraction of the cicatrix, which brought the ring within the control of a truss.

The Mountain Cure in Heart Disease.—Dr. CLIFFORD ALLBUTT read a paper on this subject. After calling attention to the growing practice of recommending exercise rather than perfect rest in some cases of heart disease, and referring to Oertel's papers, he described the plan adopted in Germany of graduated exercise by ascending hills, known as "the mountain cure." The patient, under careful supervision, was urged to walk certain paths of gradual ascent. The distress at first felt somewhat subsided, with the occurrence of perspiration, which, when the patient had attained his "second wind," was very profuse. The walks were extended each day; the diet was

Digitized by Google

largely nitrogenous, and much fluid was drunk. Dr. Allbutt remarked that cases for this treatment must be very carefully selected, as it would probably prove rapidly fatal to cases of aortic regurgitation or atrophic conditions of heart.—Dr. CHURTON thought that in some of these cases there was a contracted condition of the pulmonary arterioles, caused by impurity of blood, which would be overcome by the free elimination produced by exercise.—Dr. C. S. SMITH referred to a recent paper, in which he had put forth views similar to those advocated by the speaker.—Dr. BARRS thought that in the class of patients generally seen in hospital practice the usual treatment by rest and drugs was comparatively satisfactory.

Pasteur's Inoculations.—Dr. C. M. CHADWICK read a paper on M. Pasteur's Treatment for the Prevention of Hydrophobia. Having recently visited Paris with a view of forming an opinion on the subject, he shortly reviewed M. Pasteur's previous work, and proceeded to follow his investigations from his first case in 1880, when he discovered the presence of a microbe in the saliva (probably only an attendant on the virus, and not the true virus of rabies) and its rapidly fatal effects. Passing then to the inoculation from dog to dog under the skin, he showed how M. Pasteur expedited the process by direct inoculation under the dura mater. The uncertainty, however, of the results led to the passing of the virus through a series of rabbits, with the effect that the length of the inoculation period was much reduced. The different results obtained in dry air from those in a moist atmosphere of carbonic acid were then explained, several of the cases having been detailed at some length and commented upon. He advanced the three theories as to the *rationale* of the treatment—viz., the diminishing of the virulence, the lessening of the quantity of the virus, and finally, what appears most likely to M. Pasteur, the probable growth of some material antagonistic to the proper development of the primary virus. Having detailed the daily processes at the laboratory both for the keeping of the supply and the method of treatment adopted, he eulogised the excellent work and marvellous modesty of the discoverer of the process.—Mr. WHEELHOUSE pointed out that the cases sent to M. Pasteur from Bradford had all passed the usual incubation period of hydrophobia, as shown by one having proved fatal. Mr. LODGE gave some particulars as to the recent Bradford cases. Thirteen persons were bitten on that day, but it was uncertain whether more than six were by the rabid dog. The usual post-mortem appearances were found in the dog's body, such as foreign matter in the stomach, though there was nothing known absolutely pathognomonic of rabies.—Mr. MCGILL pointed out the small but unknown proportion of cases of hydrophobia occurring among persons bitten by rabid animals as leading to fallacies in drawing conclusions as to the process.

The discussion was adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on March 11th, Mr. R. J. Pye-Smith, President, in the chair.

Fœtal Monster.—Dr. ALFRED ROBINSON showed a specimen of a Sycephalic Monster—subvariety "Miops."

Cholesterine in Retina.—Mr. SNELL introduced a boy, aged ten, with Cholesterine in the Retina. He had been observed to be blind at two years of age. Now there was detached retina, which was much thickened at all parts, but especially so at the nasal side (right eye), where the glistening cholesterine plates were detected even by the naked eye, and were rendered very distinct with focal illumination on the mirror. The plates were clearly fixed in the retina, which appeared a littly wavy at parts. Mr. Snell remarked on the unusual condition, and said that cholesterine had been found in most parts of the eye.

Large Urinary Calculus.—Mr. THORPE exhibited a large Mulberry Calculus removed by lithotomy. It weighed four ounces and a half and measured two inches and a half in diameter. The patient was aged sixty-five, and died five days after operation. Great difficulty was experienced in the removal of the calculus, and some unavoidable injury resulted to the soft parts.

Carbolic Acid Poisoning (?) treated by Cocaine.—Mr. W. D. JAMES related this case, occurring in a man aged thirty-five. On the evening of Nov. 19th he took a dose of carbolic acid instead of the mixture ordered. He does not appear to have swallowed any. Lips blistered; buccal and pharyngeal membranes looked coated with milk; pupils dilated; pulse uncountable, partly attributed to fear. Intense pain on swallowing. Administered oil; ordered eggs and milk, a poultice to throat, and ice to be sucked. Next day no sleep; pain worse. On the 21st the area of pain had extended all over the chest; voice hoarse, and laryngeal pain with each breath. Harsh, dry respiration in larger bronchi. Temperature 102·3°. At night the pain was intolerable; voice almost entirely gone. He was ordered one-sixteenth of a grain of hydrochlorate of cocaine in water every three hours; ice and poultice continued. Next day the patient was up, and on the 24th medical attendance ceased.

Perforating Ulcer of Foot.—Mr. C. ATKIN read a paper on this subject, and drew attention to the peculiar deformity of the toes met with in some instances.

A meeting was held on March 25th, when the following specimens were exhibited.

Sarcoma of Cervical Vertebræ.—Mr. W. W. BANHAM showed a specimen of Sarcoma originating in the bodies of the third and fourth Cervical Vertebræ, infiltrating and softening the bone, and so compressing the cord.

Cystic Disease of Kidney.—Mr. BANHAM also exhibited this specimen of surgical kidney, in which a number of cysts had developed. The cysts were filled with cheesy matter. The case was one of bladder mischief, and the walls were found much thickened; there was a sinus in the ischio-rectal region, and the bladder was perforated in the posterior wall and led to a cavity in the perineum.

Rupture of Intestine.—Mr. LOCKWOOD exhibited this specimen from a lad, who had been kicked in the abdomen on the evening of March 20th. He was admitted into the public hospital under the care of Dr. Keeling; he was sick and complained of pain after the accident. The next morning he was twice sick; the abdominal pain was increased; there was no external sign of injury; he died at 4.30. At the necropsy there were signs of recent peritonitis, and a rupture in the gut about the junction of the jejunum and ileum.

Constricted Intestine with Rupture.—Mr. LOCKWOOD also showed this specimen from a patient of Dr. Keeling's. He had been operated upon for strangulated hernia. The intestine was ruptured.

Mr. KILHAM exhibited a specimen of Ruptured Aorta from a man aged thirty, a tramp, who fell suddenly dead whilst scrubbing the floor; and a specimen of Diverticulum of Ileum from a man aged fifty-eight, who died of cancer of the liver. It was situated about a foot from the ileo-cæcal valve, and projected from the lower border of the ileum.

Mr. C. F. COOMBE exhibited specimens of (1) Fatty Kidney; (2) Cirrhotic Kidney, Hæmorrhage into Pons; (3) Tubercular Kidney, Caseous Degeneration.

The Present Position of Therapeutics.—Dr. HUNT, after a brief retrospect of the history of therapeutics, went on to show that medicine was influenced by fashion, which arose from certain remedies being associated with certain diseases. Another influence that was brought to bear on medicine was public opinion. He thought that experimental research had not been successful in establishing therapeutics on a true scientific basis, and that the principle of arguing from a physiological condition to a morbid one was not sound, and did not in practice correspond with theory. It was further shown that medicinal agents can never be called curative, their only use being to treat symptoms. Another character of modern therapeutics was its approach to surgery and the influence surgery had brought to bear on the medical art. Dr. Hunt mentioned the value of certain recent drugs in certain morbid conditions, and concluded by giving his opinion on the relation that should exist between the medical man and the public.

At the meeting on April 8th,

Mr. JEFFREYS exhibited a large Biliary Calculus the size of a pigeon's egg, passed per anum.

Mr. GARRARD exhibited a Breast removed for Cancer.

Popliteal Aneurysm.—Dr. KEELING introduced a patient, aged thirty-two, for whom he had ligatured the femoral artery for Popliteal Aneurysm, with most satisfactory result. Flexing the limb and the application of a tourniquet had been tried at first without benefit. The artery was tied with a catgut ligature and antiseptic precautions were adopted. The patient, who was the subject of cardiac

Digitized by Google

disease, made an uninterruptedly good recovery.—Remarks were made by the President and Mr. Garrard.

Perforating Ulcer of Stomach.—Dr. BARTOLOMÉ related particulars of a case in which death resulted from Perforating Ulcer of the Stomach. The patient had been suddenly seized with severe abdominal pain, after partaking of a hearty tea, death resulting in twenty hours. For some time previously she had complained of pain below the ensiform cartilage, but the symptoms, Dr. Bartolomé said, were not characteristic of gastric ulcer. The specimens were exhibited, showing a large perforation in the posterior wall of the stomach.

Malignant Disease of the Throat; Laryngotomy; Pyæmia; Pneumonia; Death.—Mr. KILHAM related this case. The patient was a man aged fifty-three; he was admitted into the Workhouse Hospital on January 16th with extensive cancer of the soft palate, uvula, both sides of the fauces, and the base of the tongue, and large swellings at the angles of the jaw of about six months' duration. Laryngotomy was performed for urgent dyspnœa on Jan. 22nd. On Feb. 2nd the right shoulder became painful, with effusion, and on the 4th the left was affected. On Feb. 7th pneumonia set in, and he died on the 10th. At the post-mortem examination a large abscess was found under the right sterno-mastoid; both shoulder-joints contained pus; the submaxillary glands were indurated, and the malignant disease had extended to the epiglottis,

Fever.—Mr. BROWNING read an interesting paper upon this subject. He commenced with a brief review of the views held by Cullen, Watson, Addison, and Alison. Sir Wm. Jenner was the first to fully differentiate the various characteristics of typhus and typhoid. Admitting that, in typical cases of these two forms of fever, there is but little difficulty in making a differential diagnosis, yet the author of the paper claimed that there are numbers of cases in which the characteristics of each are not so clearly marked, and in which a diagnosis is a matter of considerable difficulty. Mr. Browning put two questions to the meeting. First, is it possible to have typhus fever without a rash of any kind; and, if so, does it frequently happen? Secondly, Is there any specific form of fever known as typhoid which is not enteric—i.e., with Peyer's patches unaffected? To the first of these questions, as the result of his own personal experience, he was inclined to answer in the affirmative. He believed he had seen cases in which all the well-marked features of typhus have been present, except the rash. To the second question he did not feel in a position to make any definite reply.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on Wednesday, March 17th, Mr. Lawson Tait, F.R.C.S., in the chair.

Mr. JORDAN LLOYD showed a boy who had had well-marked symptoms of an Abscess in the lower end of the Tibia. The bone was trephined and a small collection of pus evacuated, from which time the symptoms rapidly subsided.

Mr. EDWARD FREER exhibited a Divided Plaster Jacket for Spinal Curvature.

Dr. CARTER read a commentary on a case of Enteric Fever.

Transfusion Apparatus.—Mr. LAWSON TAIT showed the apparatus used by Professor Annandale of Edinburgh in transfusion, and read the following account of the operation. 1. The vein having been selected and exposed, a double catgut ligature is passed around it; the vein at the lower part of the wound is then securely ligatured. An opening is next made in the vein and the glass nozzle inserted, pressure being kept up on the india-rubber tube. The other ligature is now tied with a single knot around the vein and nozzle, and the ends held by an assistant. 2. The giver of the blood is meanwhile bled into the glass measure containing two ounces of the phosphate of soda solution; this will require six ounces of blood. This vessel must be kept at a temperature of about 100° by means of hot water in a basin, and the blood and solution stirred carefully with a glass rod during the remainder of the operation. 3. The glass syringe is now filled with the mixture of blood and solution, care being taken to expel all the air. The syringe is next inserted into the small piece of indiarubber tubing, from which pressure can now be removed and the blood very slowly injected. The syringe must be kept warm by means of hot flannel cloths. The point of the syringe should be directed downwards to avoid the entrance of air into the vein. When the syringe is emptied, pressure is again made on the tubing and the syringe refilled as before. After all the blood is injected the glass nozzle is removed from the vein, the ligature at the same time being tightened and secured. The wound in the skin is then stitched up. The time occupied in injecting the eight ounces of the mixture (about three syringefuls) should be about twenty minutes. The phosphate of soda solution consists of one ounce of phosphate of soda to twenty ounces of distilled water. This solution should be freshly prepared, and one part mixed with three parts of blood. All the apparatus should be carefully washed with distilled water.

Azoturia.—Dr. SUCKLING showed a specimen of urine passed by a man aged forty-seven, who complained of insomnia and restlessness. The urine was acid, sp. gr. 1030. A copious deposit of nitrate of urea was at once thrown down on adding nitric acid, and the percentage of urea, by Squibbs's process was 3·4. The average daily quantity of urine was forty-four ounces. The patient was ordered milk and farinaceous food; immediate relief followed.

Dr. SUCKLING also showed a well-marked case of Post-hemiplegic Tremor.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on Friday, April 2nd, R. E. Carrington, M.D., President, in the chair.

Stricture of the Urethra.—Mr. JOHNSON SMITH, F.R.C.S., read a paper on Stricture of the Urethra. He dealt with the various methods of treating the stricture by dilatation, and advocated gradual continuous dilatation. He laid great stress on the utility of a hot bath and the internal exhibition of opium before attempting to pass an instrument in cases where great difficulty might be expected. A good discussion followed, in which the President, Dr. Purvis, Mr. Lockhart, Mr. Moore, Dr. Moon, Mr. J. P. Purvis, Dr. Johnston, and Dr. Ernest Clarke took part.

Paroxysmal Hæmoglobinuria.—Dr. ERNEST CLARKE showed the urine of a patient under his care in the Miller Hospital. The patient was thirty-five, married, had suffered a great deal from rheumatism, and was admitted into the hospital to have some adhesions in the elbow-joint broken down. While in the hospital she had two attacks of hæmoglobinuria, there being a week's interval between each. The attack consisted of a rigor, during which the temperature rose to almost 102° from normal; this was succeeded by a rapid fall of the temperature to normal, accompanied by profuse sweating, and shortly followed by the passage of porter-coloured urine. The urine gave the blood-test with guaiacum, and precipitation of albumen with heat and nitric acid; under the microscope no blood-discs were seen, but only masses of yellow pigment. The patient had lived the first fifteen years of her life in Cambridge and latterly in Lewisham—both somewhat aguish districts; she had never had any other form of ague. The last few years she had been subject to attacks of paroxysmal hæmoglobinuria after exposure to cold; she had sometimes had an attack at night when in bed. The patient wore an anxious expression, and her skin had a very "earthy" appearance. The special interest of the case lies in the fact that the patient is a female, and that she had the attacks at night. It is also interesting to note the association of rheumatism.

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.

A MEETING of the above Society was held on Thursday, March 4th, F. E. Manby, F.R.C.S., President, in the chair.

Amputation of Breast for Cancer.—Mr. VINCENT JACKSON exhibited a woman aged fifty-eight, whose right breast he had amputated thirteen years since for cirrhous cancer. At the present time she is in good health. There is no evidence of any return of the disease. Four years previously to the operation an unmarried sister had her left breast removed for the same disease, and she also continues quite well. Mr. Jackson stated that this case and two others, one being an example of the removal at the same time of both breasts, were the only instances of a long survival after excision of the breast out of the total number of cases in which he had performed this operation.

Paralysis following the Injection of Iodo-glycerine for the treatment of Spina Bifida.—Dr. LYSETT exhibited a girl aged six years, who at birth was the subject of spina bifida over the upper part of the sacrum, forming a tense sessile tumour the size of an orange, having an ulcerated surface of the area of a crown-piece, which, on healing, formed a thin membranous covering to that portion of the sac; becoming thinner through expansion, it was tapped when she was six weeks old. An ounce and a half of fluid was drawn off, and forty minims of iodo-glycerine injected, with a negative result, the sac refilling. A week afterwards, about an ounce of fluid was withdrawn, and the injection increased to a drachm and a half, causing the sac in a few days to become obliterated, but coincidently with shrinking, however, came loss of sensory and motor power in the legs, with incontinence of fæces and urine, the paraplegia, which has persisted, being complete below and incomplete above the knees. Hydrocephalus also commenced immediately after the operation, and gradually increased until the third year, when the fontanelles closed without developing any more phenomena or impairing mental power. The horizontal circumference of the head now measures twenty-two inches. In the report of the committee appointed by the Clinical Society of London to inquire into the subject of spina bifida, there is a case recorded where paralysis supervened and persisted after the cure of the tumour, and appeared to be due to the treatment adopted. In several cases temporary paralysis occurred, which passed off in a variable time; once complete paraplegia, which subsequently disappeared. In three cases hydrocephalus set in subsequently to the cure of the spina bifida. Of the various operative measures, that by the injection of iodo-glycerine is recommended in preference to any as promising the greatest success, though the table of results shows that of 71 cases only 35 recovered, 27 died, 4 were relieved, and 5 unrelieved; and as evidence of the frequency and serious nature of this affection, it appears that it caused no fewer than 647 deaths in 1882, of which 615 were in children under one year of age.

Reviews and Notices of Books.

The Essentials of Materia Medica and Therapeutics. By ALFRED BARING GARROD, M.D., F.R.S., Consulting Physician to King's College Hospital. Eleventh Edition. Edited by NESTOR TIRARD, M.D., Professor of Materia Medica and Therapeutics at King's College. London: Longmans, Green, and Co. 1885.

A Handbook of Therapeutics. By SYDNEY RINGER, M.D., Professor of the Principles and Practice of Medicine in University College. Eleventh Edition. London: H. K. Lewis. 1886.

WHEN a work has attained the dignity of an eleventh edition we hardly know whether to congratulate the author or tender him our respectful sympathy. The first blush of success is over, the congratulations of friends are forgotten, and he keenly feels that it is no easy matter to keep pace with the progress of a subtle science which day by day advances with giant strides. There are two courses open to the popular author: either he may endeavour to keep his book what publishers call "a going concern" by his own unaided efforts, or he may retain the services of a young and active junior. The latter is the plan which has been adopted by Dr. Garrod. The first edition of his well-known work on Materia Medica was published as far back as 1855, the author being then Professor of Materia Medica, Therapeutics, and Clinical Medicine at University College. It was at its first appearance a modest little book containing a great deal of valuable information in its 280 odd pages. It was nearly ten years, however, before another edition was called for, and by that time the author had seceded from University College and had accepted a professorship at the rival school. The fourth edition appeared in 1874, and was the first, we believe, issued under the able editorship of the late Dr. Buchanan Baxter. The present work has been revised and edited, "under the supervision of the author," by Dr. Nestor Tirard of King's College. Dr. Garrod in his preface says: "The task of re-editing the book has been mainly entrusted to my friend and former pupil, Dr. Tirard, who has devoted much time to the study of the therapeutic action and chemical properties of many important medicines, and upon whose ability and accuracy I can fully rely." The book has increased somewhat in bulk, but the changes in the text are fewer and of less importance than might have been anticipated. There have been some alterations in type and sundry paragraphs have been introduced from the British Pharmacopœia; but beyond that there is really very little fresh worthy of record. The assertion that cocculus indicus and picrotoxine are not used internally in medicine is a legacy from the first edition; a great many papers have, however, been written on the subject during the last ten years, and many will remember that in 1875 the Academy of Medicine of Paris awarded a prize to Planat for his investigations into the physiological action and therapeutic uses of these drugs. We must, however, congratulate Dr. Garrod and Dr. Tirard on the eleventh edition of the work.

Of Dr. Ringer's well-known "Handbook of Therapeutics" we can only speak generally in terms of praise. The first edition was not published until 1869, but we have no hesitation in saying that it has practically revolutionised the science of which it treats. We turn with pleasure to the articles on Pilocarpine, Muscarine, Gelsemine, Nitro-glycerine, Duboisine, and Hamamelis, all of which give indications of good, sound, original work. The great feature of the present edition is the chapter on Cocaine, by Dr. Dudley-Buxton, Administrator of Anæsthetics at University College Hospital, who is also responsible for the articles on Chloroform, Ether, Nitrous Oxide Gas, Bichloride of Methylene, Ethidene, &c. Dr. Buxton has performed his task in a manner which marks him as a clear and lucid writer. We must confess that we are somewhat disappointed with some of the more recent contributions, although we fully admit that an author can hardly be expected to be equally conversant with all branches of his subject. The brief notes on Cascara Sagrada certainly fail to do justice to this valuable remedy for chronic constipation. The absence of reference to the published papers of other investigators gives at times an appearance of egotism to the work, which we are sure is unintentional. The whole book is still badly edited, and stands sadly in need of thorough revision. When Dr. Ringer gravely informs us that his friend, Mr. Joseph Bartlett, has *recently* employed actæa racemosa in the treatment of lumbago with considerable success, we cannot help feeling that he is strangely oblivious to the passage of time. He expresses his obligation in graceful terms to Dr. George Bird, who has assisted him with so many editions. Notwithstanding these imperfections, Ringer's Therapeutics will always be popular both with practitioners and senior students.

Contributions to Pathology and the Practice of Medicine. By JOHN RICHARD WARDELL, M.D. Edin. London: H. K. Lewis. 1885.

THE author of the essays contained in this handsome and bulky volume passed away from the scene of his labours shortly after the work was published. He was widely esteemed, and was indefatigable in medical research. The variety of subjects treated in the book, which remains as a memento of the man and a record of his life work, testifies to the wide experience he gathered. The volume is mainly valuable as embodying the results of that experience, for its contents range from the lengthy essay upon Relapsing Fever, written as a graduation thesis more than forty years ago, to the articles upon Hypertrophy of the Heart, contributed to "Quain's Dictionary of Medicine," and those on Diseases of the Spleen, Diseases of the Pancreas, Enteralgia, and Peritonitis, contributed to "Reynolds's System of Medicine." Amongst the more important papers —there are no fewer than fifty in all—are those upon

Digitized by Google

Enteritis, Ulceration of the Bowels, on Pleuritic, Serous, and Purulent Effusions, Chronic Ulcer of the Stomach, Carcinoma of the Stomach, and Typhoid Fever. They strike one as the product of an able mind, and contain many instances of accurate and careful observation. The following statement of the results of 36 cases of pleural effusion is worth quoting. It illustrates well the progress that has been made in the treatment of this condition:—"Of the 36 cases above given 24 were in males and 12 in females. The average of their ages was twenty-four years; 10 were from two to ten, 8 from ten to twenty, 5 from twenty to thirty, 8 from thirty to forty, 1 from forty to fifty, 3 from fifty to sixty, and 1 was aged sixty-five. In 12 the disease occurred in the *right* side, in 23 in the *left* side; 17 recovered through medical treatment, and various external applications were employed to promote *absorption*. In 17 the *trocar* or *aspirator* was employed. In 6 the fluid drawn off was *serous*. In 11 the secretion was *purulent*. In 2 the instrument was introduced, but no fluid was emitted on account of adhesion of the lung to the chest wall and plastic formations. In one instance a spontaneous opening had existed for more than twenty years. In some closures of the passage the cannula was employed with great relief. In one sudden death occurred from syncope after the operation had been decided upon; three quarts of purulent fluid were found in the left chest, and also that the kidneys were diseased. In one case the purulent formation existed seven years and a half, and full and perfect recovery resulted. Thirty-one of the 36 *recovered;* one was relieved and lived many years after, though the opening remained unclosed, and 4 *died*." We would gladly extend our quotations did space permit, but must be content to refer the reader to the book itself. In spite of its somewhat heavy style, it cannot fail to instruct as well as to suggest material for thought, whilst the hopeful views taken by its author on the progress of scientific medicine in the essay that closes the volume—an essay written apparently but a few months before his death—show how fully he appreciated all the advances made during his time and within his knowledge.

The Races of Britain. A Contribution to the Anthropology of Western Europe. By JOHN BEDDOE, M.D., F.R.S. Pp. 271. Bristol: Arrowsmith. London: Trübner and Co. 1885.

DR. JOHN BEDDOE is already well known by his valuable work on the "Stature and Bulk of Man," which was published some twenty years ago. The present work, as he tells us in the preface, is an expansion or development of a manuscript essay which in 1868 carried off the great prize of the Welsh National Eisteddfod. It is replete with interesting facts, and will rivet the attention of all those who are interested in the history of our own people. Dr. Beddoe was induced, he tells us, to take up this subject in consequence of the difference of opinion that formerly existed in regard to the colour of the hair of the Celts, and he resolved to make observations on colour phenomena on a large scale, which might afford to anthropologists some trustworthy material on which to build, or at least to test the permanence of characteristics which were by some treated as fugitive, by others as well-nigh everlasting. He has himself come to regard the colour of the hair and eyes as very permanent. He thinks it does not vary in the same family or in the same tribe more than the form of the head. He acknowledges the great difficulty that exists in determining from ancient writings the precise meaning which should be attached to these expressions indicating colour, and even in modern observations differences in description are met with which, as he rightly observes, cannot be duly estimated without a knowledge of the personal equation of the observer. Thus, most French anthropologists say that the majority of persons in the north of France are blond; whereas almost all Englishmen would say they were dark; each set of observers setting up as a standard what they are accustomed to see around them when at home. Dr. Beddoe dwells on the lamentable defect of craniological measurements of English ancient and modern skulls, and gibbets the late Dean MacNeile, who destroyed, unmeasured and undescribed, the fine mediæval ossuary at Ripon. The only collections now remaining are those of Hythe, Rothwell, and Micheldean.

In regard to the persistence of prehistoric races in Britain, Dr. Beddoe thinks that the palæolithic race, which Boyd Dawkins maintained to be the ancestors or relatives of the Esquimaux, may have left some descendants, the traces of whom may be seen in the modern population of Wales and the west of England, characterised by the oblique or Chinese eye, and other Mongoloid characters.

From various evidence Dr. Beddoe concludes that the Belgæ were a Celtic-speaking, and to some extent in blood and physique a Celtic or Celtiberian people in Gaul, Asia, and Britain; the Galatians being the representatives of the Celts in Asia. He does not appear to think that the Roman occupation left any deep or extensive ethnic changes in Britain. The influence of the Anglo-Saxon Conquest and period is very complex, and is given by Dr. Beddoe in great detail for each part of the country. Then follows an account of the effect on the population of the Norman Conquest.

The work is illustrated by many maps and by numerous tables, the preparation of which must have cost Dr. Beddoe infinite pains and trouble, but which add greatly to the authority of his statements. There are also some excellent drawings of characteristic faces and heads. The treatise will interest everyone who desires to obtain some information of the origin of the men and women by whom he is surrounded in any part of the country.

Lectures on Dietetics and Dyspepsia. By Sir WILLIAM ROBERTS, M.D., F.R.S. London: Smith, Elder, and Co. 1885.

THE experimental observations to which Sir W. Roberts has so fruitfully devoted himself are doing much to instruct the profession upon the very important subject of food and its digestion. We already owe him much for the light he has thrown upon the preparation and digestibility of foods, and in the publication of these lectures he has added to our indebtedness. The reader of this book will find therein very satisfactory explanations respecting the relative value of such common food accessories as tea, coffee, cocoa, and alcohol, based on experiments upon artificial digestion (salivary, gastric, and intestinal). In some cases the results obtained will come as a revelation; but as they in the main harmonise with prevalent ideas respecting the etiology of dyspepsia, it would be mere folly to cavil at them because they are only laboratory researches. Nor could the questions be tested in any other way. We shall not anticipate the reader's pleasure by any extracts from the book. Some of its conclusions were brought under notice by the author in his address at Cardiff; and we may content ourselves with recommending practitioners to study the facts for themselves; for they are presented in a manner which enables them to be readily understood, and their bearings upon digestive derangements easily grasped.

THE decision by which a medical man named Moore, of Thornton Heath, obtained a verdict for £600 damages against the Lambeth Waterworks Company for injuries sustained by falling over a fire-plug above the level of the pavement, was on the 17th inst. reversed by the Court of Appeal, which held that the company, being under no obligation to repair the pavement, had been guilty of no negligence.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The anuual meeting of this Society will be held at the Holborn Restaurant on Tuesday, May 18th, at 6.30 for 7 P.M.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1886.

BY the verdict of the jury at the Central Criminal Court on Saturday last another celebrated case has been, legally speaking, removed from the catalogue of crimes, though left by that verdict in an atmosphere of suspicion. However strong was the suspicion, there was certainly not sufficient evidence to prove beyond all reasonable doubt that a murder had been committed. The whole course of the BARTLETTS' married life seems to have run in such peculiar grooves, and to have been directed by influences so unnatural, that, to say the least, it was well-nigh impossible to measure with accuracy the full meaning of any particular circumstance connected with it, when judged by the light of circumstantial testimony alone. Reading between the lines, however, it may be gathered that, although to outward appearances Mr. and Mrs. BARTLETT lived on mutually affectionate terms, there was much to render their existence anything but happy and contented. When the principles of *Esoteric Anthropology* are made the guide of wedded life, the instincts and cravings of human nature find no fitting opportunity for their normal manifestation and satisfaction. We were glad to read the condemnation passed by the learned judge who presided at the trial upon literature which, whatever the intentions of the author, is fit only to be burned by the public hangman. It is little to the credit of the deceased man that he not only indulged in such unsavoury mental aliment, but allowed and encouraged his young wife to join him in his errant course. We are not now concerned so much with the psychological aspect of the "Pimlico mystery" as with its physiological and medico-legal bearings; still, wherever crime is alleged there is usually motive suggested, and naturally one is eager to inquire into the antecedents of the parties charged. Now, although we fully subscribe to the verdict of acquittal, we cannot help thinking, if the evidence bearing upon Mr. DYSON'S position in the home of the BARTLETTS be accepted as true, there was room for grave suspicion against the two persons originally charged in the indictment, considering the facts which transpired on and after the 28th of December. That these suspicions fell short of proof was acknowledged by the prosecution when they decided to offer no evidence against Mr. DYSON, and by the jury when they brought in Mrs. BARTLETT "Not guilty."

In the Scotch Courts the verdict on Saturday would have been "Not proven," certainly a more logical way of recording the finding in the present case. There is one exception that might be taken, perhaps, to the general soundness of the summing up of Mr. Justice WILLS: we refer to the question of the probabilities of suicide. It is true there was nothing to show that the deceased contemplated putting an end to his existence; but with a mind like his—if not unsound in a technical sense—distorted by morbid sensations and beliefs anything but indicative of mental equilibrium, and with a body weakened by many days of suffering and sleeplessness, it is not too great a stretch of the imagination to suppose that, seeing the "instrument" ready to hand, he may have been seized with an irresistible impulse to use it; without assuming design or prior intent to commit a felonious act upon himself. Then, again, the chloroform may have been taken accidentally by the deceased; or wilfully, but in ignorance of the consequences likely to ensue; or whilst in a half-dazed condition when waking from unrefreshing sleep. The purchase of the chloroform by Mr. DYSON at the request of Mrs. BARTLETT, the certain death of Mr. BARTLETT by swallowing the drug, and the disappearance of the bottle which contained it, formed a chain of events which required all the forensic talent of Mr. CLARKE to loosen and unlink to the satisfaction of the jury.

That the chloroform gained admission to the stomach of Mr. BARTLETT during his lifetime there could be no shadow of doubt, for there were unequivocal signs of its irritant action upon the mucous membrane. And in the absence of any other discoverable cause of death—although, if we remember rightly, no mention was made of a chemical examination of the urine, or of inspection of the spinal cord or suprarenal capsules—the inference was fair that deceased succumbed to the combined irritant and narcotic effects of chloroform. In fact this was not seriously challenged by the counsel for the defence. According to WHARTON and STILLÉ, "when death has been produced by the internal use of chloroform its local irritant action has evidently been the chief cause of the fatal result." To this dictum we must emphatically demur, since the exhaustion that would naturally follow the continued action of such a powerful irritant is minimised by the toxic and soporific effect of the poison absorbed into the system. The acute inflammatory action set up in the stomach by swallowed chloroform fails to induce fatal shock, just because the sensorium is lulled into quietude and stupor. A parallel example is furnished every day by the performance of otherwise painful operations whilst the patient is in a state of anæsthesia. In Mr. BARTLETT'S case the inflamed and eroded area was situated on the posterior surface of the stomach in the direction of the œsophagus; but this is just what might have been expected, whether the chloroform was administered by himself or some other person, providing the body lay on the back during the greater part of the time that elapsed between the act of swallowing and the advent of death. As an argument in support of the contention that Mrs. BARTLETT was responsible for the administration, it was practically worthless.

Let us suppose for a moment that Mrs. BARTLETT actually gave the chloroform to her husband. We then have to ask, What are the alternatives as to the means adopted? In the first place, it might have been by inadvertence—a supposition that may be discarded without further consideration, for the pain and stifling effect would have sufficed at once to have led to a recognition of the mistake; and of course this holds good as regards the theory that Mr. BARTLETT was the sole active agent of the misadventure. Having eliminated the question of accident, we now turn to the accusation set forth in the indictment. The Attorney-General, in his opening speech for the prosecution, to all intents and purposes told the jury that before they could convict they must satisfy themselves that the deceased was first stupefied or rendered

Digitized by Google

insensible by inhalation, and that while in this condition the fatal draught was administered. Nor, on the supposition of Mrs. BARTLETT's guilt, could he consistently with a show of probability have followed any other course. It would, to our minds, have been idle to expect the jury to be convinced that the chloroform was given solely in the liquid form, disguised or not by admixture with alcohol or other fluid. Mr. CLARKE, in his able address, asked the jury to believe how utterly unlikely it was that Mrs. BARTLETT should select for the carrying out of her alleged purpose a drug which hitherto had not been employed to compass homicide. The pleading on this point was not devoid of all show of reason, but to adopt it as unanswerable would, if followed to its logical conclusion, amount to this: that a jury ought not to convict a prisoner of the crime of murder, because there was no precedent as regards the means recorded in the history of forensic medicine. PALMER was convicted and hanged for having poisoned COOK by strychnia, although the alkaloid was virtually unknown to the criminal law, and in spite of chemical analysis having failed to discover it in the stomach and tissues of the victim. So, too, in LAMSON's case, there was little or nothing in the form of previous experience to aid the investigation of the question of poisoning by aconitine.

Stripped of its associated elements of motive and suspicion, the proof of Mrs. BARTLETT'S alleged guilt could only rest upon the ability of the prosecution to tender trustworthy evidence as to the likelihood of the accused succeeding, in the first place, in administering chloroform by inhalation to a sleeping man, and, secondly, in giving a fatal liquid dose of the same drug to a person in a state of narcotic stupor. The testimony of Dr. STEVENSON and other witnesses showed that, although each act might be accomplished, it would, nevertheless, be a task of no ordinary difficulty, and, in short, so arduous and uncertain of attainment that a medical man, possessed as he would be of special experience and knowledge, might fail in the attempt. At a trial for attempted murder by the administration of chloroform vapour, which took place on Jan. 18th, 1871, at New Bloomfield, Perry County, Pa., Dr. MAURY said: "I experimented with chloroform on six sleeping persons. Out of that number all resisted more or less. Two men woke up immediately, and one remarked, 'You are trying to give me something.'" With opinions stated so guardedly, and rightly so, we maintain that the verdict returned in the BARTLETT case will meet with general approval by the profession. Since writing the above we have read in the daily journals a letter from the foreman of the jury, in which he says eleven of their number were in favour of finding that deceased took the chloroform himself, either from a desire to procure sleep or with the intent to commit suicide.

Concerning the necrosis of the jaw and its attendant symptoms, Mr. LEACH formed the opinion that Mr. BARTLETT was the subject of mercurial poisoning. In support of this diagnosis was the fact that, in addition to the swelling of the gums and the salivation, Mr. BARTLETT suffered from diarrhœa and hæmorrhage from the bowels. Unfortunately, the liver, kidneys, &c., were not preserved for analysis, or valuable evidence might have been thereby attained, since mercury is a poison which has a tendency to accumulate in the tissues. The only reasonable theory advanced at the trial to account for the exhibition of mercury supposed that Mr. BARTLETT may have taken the mineral for the treatment of a real or fancied disease, which a certain article found in his dress was intended to prevent. But this was nothing more than conjecture.

The case must now, and probably will for ever, remain where the jury have left it; but it will certainly long be remembered on account of the prominence given by it to the effects of poisoning by liquid chloroform.

EVER since the discussion on the case of the late President GARFIELD, in which MARION SIMS took a leading part, the question of the treatment of perforating wounds of the abdomen has attracted much attention in the United States. The most important result up to the present is a paper recently read by Professor F. S. DENNIS at the New York Medical Association, and published in the *Medical News* of Philadelphia. The purport of the paper is to show that the proper course in cases of stab and gunshot wounds involving the abdominal cavity is to explore the wound and search for and treat any visceral lesion, applying strict antiseptic treatment throughout.

Penetrating stab-wounds of the abdomen are first dealt with. Dr. DENNIS relates cases showing the difficulty of determining whether a viscus is injured or not, and the hopelessness of wounds of the intestine if only palliative measures are adopted. Two patients were exhibited in whom Dr. DENNIS had met with great success. In one of them a loop of protruded intestine had received two wounds, one two inches long; these were sutured and the bowel returned. In the other there was no prolapse, only a penetrating wound four inches above and three inches to the left of the umbilicus. The abdominal cavity was opened in the middle line, and the whole of the abdominal viscera were systematically examined. No injury was found. Both patients made good recoveries. The latter case is similar to one recently published by Mr. ARTHUR E. BARKER. Other cases are quoted to show the possibility of finding and suturing wounds of the intestine, and of thoroughly cleansing the peritoneal cavity from blood and other extravasations. Professor DENNIS gives a table of fifteen cases in which this line of practice has been successfully followed by himself and other surgeons; Mr. BARKER'S case raises the number to sixteen.

Dr. DENNIS next deals with cases of penetrating pistol-shot wounds of the abdomen. He relates two cases of his own. In one he found a wound of the liver, from which there was profuse hæmorrhage; in the other he detected seven wounds of the intestine, each of which was sutured; but in addition there was alarming venous hæmorrhage, which it was impossible to control. Death occurred in forty-eight hours, and it was then found that the intestinal wounds were firmly closed, and that "the iliac veins" were wounded. Seven cases are to be found in surgical literature where in this form of injury the abdominal cavity has been explored and cleansed and wounds of the intestine closed, the patients making good recoveries. Dr. DENNIS has only found one case recorded in which laparotomy was performed simply for a ruptured intestine, and in that case the patient died.

Digitized by Google

The conclusions that Dr. DENNIS arrives at may be thus stated. Wounds and ruptures of the intestine are certainly fatal if left alone. A properly conducted laparotomy adds little or nothing to the danger of the injury. Suture of wounds of the intestine has been proved to be a successful procedure. Although a wound of the intestine may be readily diagnosed in some cases by emphysema, by the detection of gas in the peritoneum, or by the flow of fæces from the external wound, in many other cases the surgeon is unable to assert with confidence that the bowel is *not* injured. Hence it is a justifiable procedure to explore the abdominal contents even when there is no positive evidence that they have been injured. The exploration, Dr. DENNIS thinks, is best made through an aperture in the linea alba, and not by enlarging the initial wound. This exploration, too, must be thorough and complete. In one of his cases no less than ten wounds of the ileum were detected. The surgeon must, therefore, not be content with finding and treating a single visceral lesion, but must carefully examine in an orderly manner the whole of the abdominal contents. Quite as important is the care expended to prevent the infection of the peritoneum with septic organisms, and the adoption of means for their removal if already present. Dr. DENNIS is a staunch upholder of antiseptic surgery, which he would have carried out with scrupulous attention to every detail. The antiseptic agent he prefers is bichloride of mercury. There are several other points raised more or less incidentally in this paper, but those to which we have alluded suffice to indicate its importance and value.

It is interesting to note that the late Professor GROSS, when writing on Wounds of the Intestine more than forty years ago, recommended just this line of treatment. He clearly saw the only direction in which surgery could hope to deal successfully with such cases. Our modern improved methods of wound treatment have rendered the course of action then advised not only practicable, but successful.

IT is but seven years ago that a paper by Mr. W. H. POWER on Diphtheria and Milk, read before the Pathological Society, led to a more general consideration of the question whether "cow as cow and milk as milk" were not concerned in the production of some of the more common infectious diseases of man; in other words, whether some malady of the cow were not the cause of milk infection. Mr. POWER'S reasons for urging the probability of this origin of human infectious disease were, firstly, that milk had on several occasions been definitely shown to have given rise to such disease amongst its consumers; and, secondly, the insufficiency of any evidence tending to show that the milk could have become infected after leaving the cow. The suggestion was received with some incredulity, and by some persons with apparent indignation. With regard to diphtheria and its possible relation to garget, it was pointed out that had Mr. POWER "been better acquainted with comparative pathology, or sought to be informed by those who have made cattle diseases their special study, both chemically and experimentally, he would not have troubled the Pathological Society with a hypothesis that admits of the clearest refutation," and, subsequently, "that it was not unlikely legal proceedings would be taken against the author or the Pathological Society."

Probably expression would not have been given to these adverse opinions if it had been more fully recognised that evidence tending to incriminate the cow could only be obtained by a minute analysis of all the circumstances relating to the infection of the milk drinkers. Until this evidence existed a study of cow diseases was only deemed of interest in relation to the welfare of these animals. Their ailments were valued as important only to the extent in which they interfered with cow health, and an ailment which caused nothing but a trivial indisposition, and which did not obviously affect the quantity and quality of the milk, was reckoned as a matter of small concern. So it was concerning cow-pox until JENNER showed the relation of this disease to small-pox, and so it has been since with all other slight maladies of the cow.

It does not, however, require much consideration to show that the more serious disease in the human may have its origin in a much slighter affection in the bovine animal. The relative severity of the symptoms produced by inoculation of small-pox virus in man and in the cow alone teaches this lesson. Nor is it difficult to believe that if "cow as cow" is the cause of disease in man, the malady from which she suffers and which infects man must be of not uncommon occurrence, for the ordinary human infectious diseases are too widely distributed for their origin to be rare. But the more common the cow ailment, the less has it been thought worthy of exceptional consideration. Mr. POWER, in the paper to which we have referred, pointedly remarked that, although it was affirmed that no serious illness had occurred among the cows supplying the milk which undoubtedly gave rise to diphtheria, "this affirmation does not exclude occurrence of cold or other minor ailment among cows." He has not had to wait long for further reasons for thinking that such ailment could give rise to human diseases of serious import. At this moment we are told of a certain malady occurring among cows at a time when the milk produced by them disseminated scarlet fever. The evidence that this malady caused scarlet fever is not yet forthcoming. If there is such evidence, it must be awaited until Mr. POWER'S report on the recent outbreak of scarlatina in West and North London is published; but, in the meantime, a paper which Dr. JAMES CAMERON, the medical officer of health for Hendon, has presented to the Epidemiological Society may be regarded as a notable one, although it does not profess to go further than give account of the clinical features of the affection, of which we hope to learn more from Mr. POWER and Dr. KLEIN at no distant date.

Dr. CAMERON'S story is, briefly told, of the introduction into a cowshed of certain newly purchased cows, and of the appearance of disease first among these and afterwards among other cows in this and other sheds. He describes the affection as a specific contagious disease of not infrequent occurrence, appearing usually in the first instance amongst newly-calved cows, and capable of being communicated to healthy cows by direct inoculation of the teats with the virus conveyed by the hands of cowmen. The symptoms of the disease are those of constitutional disturbance, of discharges from the eyes and nose, of vesicles on the teats and udder, and of an eruption on the hind quarters, accompanied, in severe cases, with sore-throat; and we are told the affection

Digitized by Google

can be communicated by inoculation to man, and seemingly, though perhaps in another form, by milk. Into greater detail we need not enter here; but assuming that the milk will be found to owe its infectivity to the ailment Dr. CAMERON has described, it is obvious that a very great advance will have been made in our knowledge of the pathology of human infectious disease. We appear, indeed, to be on the threshold of a discovery which may be only second to that of JENNER in its ultimate results. Etiologists have been baffled again and again in their efforts to discover the cause of cases of infectious disease occurring under circumstances that rendered it almost impossible that they should have resulted from antecedent cases. The possible relation of such disease to affections of the lower animals has recently been kept more prominently in view, but the inquiries which have been made in this direction have proved barren, except in so far as they have tended to eliminate other conditions from suspicion. At last there appears some prospect of greater success, but if this is to be attained, the study of bovine maladies must be approached in a way very different from that followed heretofore. They must be thought of in their pathological rather than their commercial relations, and certainly the best results will follow if in any further investigation their possible bearings upon the public health are more willingly recognised.

ONE of the most hopeful signs of the times in the matter of hospitals is the growing activity of those officially connected with them, whether honorarily or otherwise. This activity finds vent and expression in many ways, but chiefly through the Hospitals' Association, which is fast justifying its existence. We have recently once or twice called attention to papers read and discussions which have followed the reading of them at the meetings of the Association; notably to one on the hardship of levying local rates on hospitals, seeing they do so much voluntarily to keep the poor from becoming paupers; and another on sectarian nursing. Both these papers treat of matters of much importance, and are calculated to have practical consequences. The first gave great demonstration of the claims of hospitals to be exempted from rating, and has led to the introduction of a bill for this purpose, which is receiving powerful Parliamentary support from members on both sides of the House. The other has done much to show that sectarianism in nursing in London hospitals is the exception, and finds little favour in the best hospitals.

The annual report for the year 1885 of the Hospitals' Association is before us, and confirms our estimate of the uses of the Association in bringing together those who have special interest or skill in hospital matters. The report suggests that there are three main directions in which the Hospitals' Association can do work of real value to the hospitals and to the public. First, in the collection of facts and data concerning hospitals; secondly, in the appointment of sectional committees; and, thirdly, by the establishment of a journal to disseminate information and serve as a means of communication between hospital workers. In furtherance of the first object a central office has been opened at Norfolk House, Norfolk-street, Strand, where, under an assistant-secretary, all papers, books, and other documents will be methodically arranged and preserved for reference by members and others. This in itself is a great matter, and will tend to diffuse information and promote a healthy rivalry in administration and efficiency. We do not notice in the report any indication that the subject of hospital account-keeping has engaged the attention of the Association. This would furnish an admirable topic for a paper. We do not know any better way of promoting soundness in hospital administration or increasing public confidence in our hospitals than by trying to introduce a sound and uniform system of account-keeping. Under the second head a sectional committee on hospital nursing and domestic management has been appointed at the suggestion of Miss WOOD, the Lady Superintendent of the Hospital for Sick Children, Great Ormond-street, and includes a dozen of the lady superintendents of the principal metropolitan and provincial hospitals. They contemplate establishing a register of nurses, and giving certificates of those duly trained. The public confidence in nursing is hindered by the uncertainty of qualification and character. It will be a great gain to organise a system by which public guarantees of fitness can be given. The Committee is even entertaining the question of establishing a national pension fund for nurses and others engaged in hospital work. This seems, to us at least, rather premature, and likely to distract the attention of the Society from work strictly within its competence. On the whole, the Association gives a good account of its stewardship. It has not tackled the great question of hospital support. Perhaps it is wise in postponing this question to others affecting the efficiency and usefulness of hospitals. If these can be promoted, the public will be more quick to open its large purse and to relieve the great anxieties of those who administer these splendid charities. Those interested in the welfare of hospitals cannot do better than join the Hospitals' Association, which owes much of its success, if not its existence, to Mr. H. C. BURDETT, who is a striking illustration of the fact that a very busy man can find time to render the most valuable help to hospitals.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF PHYSICIANS.

THE special Comitia for the purpose of electing a President of the College of Physicians for the ensuing year was held on the 19th inst. There was a very large attendance of Fellows—indeed, the largest on record,—and the cordial manner in which the result of the election was received proved that there could be no question as to the desirability of Sir W. Jenner being invited to hold office for another year. The proceedings were commenced by the presentation to the College of a portrait of Sir H. Pitman. The presentation was made on behalf of several Fellows by Sir Risdon Bennett, who, in graceful and well-chosen language, pointed out the great services rendered by Sir H. Pitman, and the esteem in which he is held. The portrait, which is a very successful one, is by Mr. Ouless, R.A., and is to be exhibited in the Royal Academy; the copy which it is proposed to give to Lady Pitman was exhibited at the College on Monday. Sir W. Jenner endorsed Sir Risdon Bennett's remarks, and Sir H. Pitman feelingly replied. The President, Sir W. Jenner, then delivered his annual address. He passed in review the affairs of the College

Digitized by Google

during the past year, in the course of which he alluded to the action taken by the College to promote a scheme for giving greater facilities to students desirous of obtaining medical degrees. He expressed the hope that the two Colleges would be enabled to erect lecture-rooms and laboratories on the site adjacent to the new Examination Hall, so that provision might be made for instruction of the highest class in certain subjects. He then proceeded to sketch the careers of the eleven Fellows who had died during the past year—namely, Dr. Ed. Wells, Dr. A. B. Shepherd, Dr. T. R. Heslop, Dr. J. W. Wardell, Dr. Jas. Russell, Dr. F. Harris, Dr. Gavin Milroy, Dr. S. Monckton, Dr. S. Sutro, Dr. F. Weber, and Dr. W. A. Guy. It is needless to say that the characters and works of these deceased Fellows were described in discriminating and befitting language. On the motion of Dr. F. Farre, a vote of thanks was accorded to the President by acclamation. The election was then proceeded with, the result being that eighty-nine votes were recorded for Sir W. Jenner, and forty were distributed amongst eight other Fellows. The Registrar having declared the result, which was received with loud applause, Sir W. Jenner briefly thanked the Fellows for having done him the unusual honour of electing him for the sixth time to preside over the greatest medical institution of the country.

PROFESSOR GAUTIER ON NEW LEUCOMAINES.

THE interesting researches carried out during some years by the distinguished chemist of the Collége de France resulted in the discovery of a group of bodies resembling vegetable alkaloids, or rather the alkaloids which had been found by himself and others, to which the term ptomaines, or cadaveric alkaloids, is now applied. But the importance of his discovery lies in the fact that these bodies, to which he gave the name Leucomaines, are found in healthy living matter, and there is every reason to believe were produced by the chemical changes of assimilation and disassimilation. Whether this is the exact truth can only be proved by the results of future observers; but the physiologist is often rather shy of accepting the results of the chemist, armed as the latter is with powerful agents of chemical destruction, and it is often urged that he has himself produced the bodies he has found. Putting this question on one side, the importance of the new views to the subject of medicine can easily be seen. The living being is constantly manufacturing in his own tissues agents which can produce disease or death. We have not the same necessity to search for the ever-present etiological factors of cold and damp, or too hastily summon the microbes to explain our diseases. This discovery was, as might be imagined, seized with delight by the anti-microbists; they had scientific evidence on which to found their opinions, and it must be said that they have in no way neglected to push the theory to its logical consequences. Ever since Professor Gautier's first paper at the Academy of Medicine, about two months ago, the subject for discussion has been the same—the leucomaines *v.* the microbes; and lately a fresh support has been given to the anti-microbists by the announcement from the Professor of two new leucomaines, the poisonous properties of which are undoubted. The first body is called "adenine." It was discovered by M. Kossel of Berlin in the pancreas and spleen, and was described in Hoppe Seyler's *Zeitschrift* of March 11th. It appears to exist in all animal and vegetable cells, and can be extracted from them by neutral reagents; and, further, it appears that it is derived in the cell from the nuclein—a body already known,—since under the influence of water and heat the nuclein produces adenine, phosphoric acid, and albumen. Adenine itself can be wholly transformed into hypoxanthine or sarcine—thus showing its near relation to the bodies we vaguely call nitrogenous metabolites; but a more interesting relation is hydrocyanic acid. The formula of prussic acid is HCN; the formula of adenine is $H_5C_5N_5$, and cyanide of potassium can be produced from it. The second body was isolated by M. Morelle from the spleen. This organ was chosen by the advice of Professor Gautier because of its undoubted purifying action on the blood, being the place where alkaloidal and similar noxious products of metabolism are retained. The physiological properties of this leucomaine were tested, and it was found to be a paralyso-motor, with a powerful action on the medulla oblongata. A small quantity injected under the skin of a guinea-pig appeared at first to produce nothing abnormal, with the exception of immobility, a refusal of food, and some swelling near the point of injection for the first forty hours, but by degrees the depression and suffocation increased, and the animal died asphyxiated. At the necropsy were found congestion of the lungs with subpleural ecchymoses, general œdematous infiltration of the liver, spleen, and kidneys, and a certain hardness of the ventricles, appearing to indicate the arrest of the heart in systole.

THE REPORT OF THE MINES COMMISSION.

THE long and interesting report just published by the Commission on Accidents in Mines abounds in the practical results of much careful investigation, which has been reluctantly suspended by those engaged in the work. The inquiry, as was to be expected, has been distinguished by the variety of its subject matter. With regard to ventilation, the Commissioners agree that there is need for improvement. The sectional area of the shafts might well be increased in many collieries. The improved methods of shortening the air-courses now coming into use might be more generally applied. The employment of two parallel intake drifts, of which one forms the travelling road, is also worthy of more extended trial. Supervision of workmen, according to the report, has grown in efficiency, there being now one overseer to every twenty or even twelve men. The subject of timbering or supporting the walls of passages receives due attention, and some hints are given as to the avoidance of "miscellaneous" accidents not peculiar to pitmen. The paragraphs most fruitful in fresh suggestion are those which deal with accidents due to explosion. The mischievous effect of coal-dust in dry mines as an aid to such mishaps is well brought out. The Commissioners have experimentally proved that a percentage of marsh gas amounting to 5 per cent., or even 4 per cent., of atmospheric air is decidedly explosive. Half this proportion, however, though not in itself dangerous, and though impossible of detection by ordinary lamp tests will explode if the air be laden even lightly with fine dry coal-dust. Now, it may happen that in blasting, particularly if gunpowder be used, an overcharge in the blast-hole, or the want of sufficient "tamping" or packing with damp non-non-inflammable material, will result in the projection of the heated products of explosion, with flame, into the air of the mine. Such an event is dangerous in dry mines, though little gas be present. The coal-dust is soon alight, the explosion spreads by contact of its particles and their admixture with small quantities of fire-damp, and the worst consequences may follow. It is probable that some of the obscurer causes of accident may be thus explained. To avoid such risks the following rules have been laid down:—1. Before using powder for blasting let coal-dust be removed from that part of the mine as far as possible, and the remainder saturated with water. 2. Where this cannot be done, some other explosive than powder, which flames too readily—lime cartridge or dynamite in conjunction with water—should be used. The latter compound, indeed,

Digitized by Google

is reported to be safe even in the presence of an explosive mixture of air and fire-damp. Experienced men alone are to be employed in blasting; naked fuses and hot wires are strongly condemned; and the only means of ignition advised by the Commissioners are electric apparatus and such miners' fuses as are contrived with an appliance which fits over the blast-hole and secures their ignition while preventing the ingress of air. In conclusion, two points are specially insisted on—namely, the general employment of indicators which will show the presence of 1 per cent. of marsh gas, and to be used once or twice daily by men appointed to examine the mine, and the substitution of reliable safety lamps for naked lights, in all mines which are dusty or liable to invasion by gas. Lamp stations under ground—i.e., central points where lamps may be lit—must be carefully managed, and the more inflammable oils discarded or allowed only under certain precautions. The opinion of the Commissioners with regard to lamps is somewhat instructive. The older Davy, Clauny, and even Stephenson types have in great measure lost their value, in consequence of the rapid passage of air induced by free ventilation. A current of 800 ft. per minute in an impure atmosphere may, in spite of the wire-gauze, effect an explosion in any one of them. More recent kinds, as that of Gray and others, resist the force of a current moving at the rate of 3000 ft. per minute. Any lamp, however, is dangerous if loose in its fittings, and the only safeguard which has so far suggested itself is that every article of the kind before it is carried underground should be tested in an inflammable mixture of air and gas, which will suffice to indicate any faults of structure. Once lit it must in every case be locked. Electric lighting is already to some extent in use, and may come to be more generally adopted. It is admitted that, while it does not, like the oil-lamp, serve for test purposes, its lighting power is much greater and the risk from its use much less. The Commissioners close their report with a wish that ambulances adapted to the work of rescue in pit accidents were established throughout the coal districts, a wish which will not fail, we hope, to be realised.

CHOLERA ON THE ADRIATIC COAST.

THE cholera, which for some months past has broken out in isolated attacks in the north of the Adriatic, has made a further extension, the seaport of Brindisi being now affected. On the 15th inst. the disease was declared to be simply of a sporadic type, but the Egyptian authorities at once subjected all arrivals from Brindisi at Alexandria to seven days' quarantine; and later information is to the effect that the Austro-Hungarian Government have, in view of the unsatisfactory state of Venice, ordered seven days' quarantine for all goods coming from Italy. From Rome, too, comes news that the Sanitary Board admit that the cholera at Brindisi is of the Asiatic type, and it has itself ordered the imposition of seven days' quarantine at all Italian ports as regards arrivals from ports on the Adriatic coast.

HEMIANOPSIA.

THE March number of the *Archives de Neurologie* contains an almost exhaustive article on Hemianopsia by Dr. Seguin of New York. The value of the symptom in diagnosis is summed up in a few propositions, which, so far as our present knowledge goes, may be regarded as accurate. Lateral hemianopsia always indicates an intracranial lesion on the opposite side to the loss in the field of vision. Lateral hemianopsia with immobility of the pupil and neuritis or atrophy of the optic papilla, especially if in combination with symptoms of disease of the base of the brain, is due to alteration in the optic tract or of the lowest visual centres on one side. Lateral hemianopsia, or an analogous geometrical obscuration of the visual field, associated with hemianæsthesia and ataxic or choreiform disorders of movement in one half of the body, without obvious hemiplegia, is probably due to a lesion of the postero-lateral part of the optic thalamus or of the posterior division of the internal capsule. Lateral hemianopsia with complete hemiplegia (becoming spasmodic after some weeks) and hemianæsthesia is probably caused by an extensive lesion of the internal capsule about its knee and posterior limb. Lateral hemianopsia with typical hemiplegia and aphasia, if the right side be affected, together with more or less anæsthesia, is almost certainly due to an extensive superficial lesion in the area irrigated by the middle cerebral artery. Lateral hemianopsia with slight motor weakness of one half of the body, especially if combined with disturbance of the muscular sense, would probably be due to a lesion of the inferior parietal lobule, the angular gyrus and subjacent white matter extending deeply enough to injure or compress the optic radiations in their path towards the visual centre. Simple lateral hemianopsia without motor or sensory troubles, is due to a lesion of the cortical visual centre on the opposite side.

PUBLIC HEALTH IN TASMANIA.

PUBLIC HEALTH legislation is extending in the colonies. Under the Public Health Act of 1885, passed by the Parliament of Tasmania, each local board is required to appoint a medical officer of health; bye-laws may be made as to many subjects, including control over meat, milk, dairies, &c.; analysts may, and in some cases shall, be appointed, and clauses deal with the prevention of adulteration; the protection of infant life is specially dealt with by means of control over houses of persons receiving infants for nursing and otherwise; infectious disease must at once be reported by the local board to the central board, which has power to make regulations in such matters, and hospitals, ambulances, &c., may be provided under the statute; special powers are also vested in the Governor in Council to isolate houses and even streets in which infection prevails; and penalties are provided for the exposure of infected persons or things. As regards many nuisances, whether connected with trades, animals, or otherwise, the Tasmanian Act follows much in the lines of the English Public Health Act, but it has the advantage of simplicity in dealing with pigs, for it is expressly provided that no person shall keep any swine or a pigsty within 100 ft. of any house in any city or town, or within 50 ft. of any house in a rural municipality. Such a provision would, in this country, have prevented the overthrow of useful bye-laws affecting our rural areas, where regulations dealing with this subject are, in view of recent legal decisions, practically useless. Dr. Henry A. Perkins, of the University of Edinburgh, has been appointed President of the Central Board of Health, and we feel certain that much excellent work will be effected under his administration.

NEW APPLICATIONS OF CORK IN THE ARTS.

THE peculiar properties of cork which have led to its application to many familiar uses are probably still very imperfectly understood by the majority of the reading public. A careful exposition of its nature by Mr. William Anderson at the Royal Institution comes therefore in good time, and opens up a prospect of wider and more important adaptations of this singular substance in the arts. The essential character of cork consists in its retentive porosity with regard to air. In other words it is a substance composed of fine closed cells whose walls permit the gradual entrance and storage of air while they resist its ready egress, or the entrance of denser fluids. It is therefore not only a gas-holding but a gas-retaining substance, and as such possesses in a greater degree than any other solid the

Digitized by Google

power of allowing cubical condensation from pressure applied in all directions. It is proposed in various ways to carry out in practice this explanation of the nature of cork. It may be employed, for example, in hydraulic apparatus where the air-laden cork will take the place of air itself, and Mr. Anderson was able to show that in some cases, at all events, it was competent to discharge this function. A suggestion was made that the porosity of cork rendered it a fit substance for the construction of overcoats, and greatly preferable to indiarubber in this respect. The latter part of this suggestion we have no difficulty in conceding, and we hope that experience will prove that it is wholly justifiable. Cork underclothing has been advocated by some on similar grounds; but this proposal does not in our opinion guarantee the wearer the comfort and sanitary advantages which are conferred by the use of wool.

THE AMERICAN MEDICAL ASSOCIATION AND THE INTERNATIONAL CONGRESS.

THE meeting of the American Medical Association takes place on Tuesday, May 4th. The meeting will be of more than usual importance. The approach of the time for the International Medical Congress makes everyone anxious for its success, and about the action of any Body or any persons that may influence the event. The American Medical Association is one of those bodies which may do much to mar or to make the Congress. We venture to hope that it will not interfere with the executive committee now appointed and apparently doing good work in organising the Congress. This committee was intended to be quite independent, and we gather from the journal of the Association that this independence will be respected. The death of Dr. Flint is a profound fact and factor in the question. Whatever may have been the differences between him and esteemed contemporaries in the United States, we cannot doubt that his death will greatly obliterate the sense of these and intensify the desire to bring the Congress, for which he laboured so much, to an issue worthy of America and of the cause of international medicine. Probably no other death could have caused quite the sense of loss in medical circles in Europe which the removal of Dr. Flint has caused at this moment. But the best consolation of his friends at home and abroad will be the success of the Washington meeting.

FEMININE PRURIENCY.

WE do not specifically speak of the pruriency of females, though, of course, this vice—for we can call it by no less opprobrious name—attains its highest development in women; but of that particular pruriency which, because females more frequently manifest it, must be regarded as feminine, and which, indeed, has all the feeble filth-love that prompts to the indulgence of prurient curiosity among women of worthless character or debased mind. Hard as it may be to define this graceless quality of the feminine nature, whether occurring in unwomanly women or unmanly men, everyone will recognise its existence, and no right-minded person can regard its manifestation without regret. The judge presiding at the recent trial at the Old Bailey did not condemn this monstrous evil too severely. The fact that women crowded the court, and were not abashed by evidence which no decent newspaper would print, must be held to reflect injuriously on the morals of the day. What, however, is to be said of the mismanagement, or worse, by which a court of justice was reduced to the level of a place of public entertainment of the lowest description? The judge compared it to a "theatre." By so doing he did a wrong to the class of theatrical managers and the Lord Chamberlain. No theatre—in this country, at least—has within the memory of the oldest inhabitant been degraded to the level of the Old Bailey during the recent trial. Why were extra seats provided, or, being provided, why were they allowed to be occupied by women not one whit less despicable than those who brought their knitting and sat and gloated over the spectacle while heads fell under the guillotine? There is blame to cast somewhere, and in the interests of public morality it should be brought home and pressed on the wrong-doers. We cannot determine which is the most significant fact—that women should have been found to crowd the court, or that they should have been permitted thus to disport themselves. We hear of the enfranchisement of women, of their gentleness and purity. Heaven help the morals of this land when the spirit of feminine pruriency displayed in this last public scandal has attained yet higher supremacy, and the Newgate calendar replaces the work of elegant extracts in the boudoir, while the Old Bailey is the chosen place of entertainment for the mothers and sisters of Englishmen.

THE CONDITION OF THE BLOODVESSELS IN EPITHELIOMA.

A NUMBER of observations on the changes in the bloodvessels accompanying epithelioma have been carried out in Professor Ivanovski's laboratory in St. Petersburg by Dr. Nikolai Yakimoff. He divided his cases into two series. In the first, consisting of fifteen cases, the bloodvessels in the locality of the new growth only were examined, and in the second series of five cases the observations extended to the other organs and bloodvessels of the body. These observations show that the bloodvessels not only near the tumour, but generally throughout the body, become affected, both the larger and the smaller having thickened walls and a diminished lumen. The thickening of the walls affects all three coats, the middle and inner coats being more affected than the external. Hypertrophy and hyaline degeneration both occur, beginning in the small vessels and gradually extending to those of larger size. Hypertrophy is caused by the multiplication of the cellular elements of all three coats, but the white blood-corpuscles may assist in the increase of the external and internal coats, especially in that of the intima, when it happens to be affected by endo-arteritis obliterans. Hyaline degeneration proceeds mostly in young cells which are not fully developed, and in old ones in which proliferation is commencing. This hyaline degeneration may commence either in the nucleus or in the protoplasm of the cells, but most commonly does so in the latter.

LEGAL MEDICINE IN ITALY.

SINCE Puccinotti's great work "Trattato di Medicina Legale," followed by his "Trattato Medico-legale sulle Ferite," published more than fifty years ago, this important branch of medicine has rather languished in Italy. Quite lately, however, it has shown signs of recovering. The Cavaliere Nicola De Pedys, a graduate of much distinction in surgery and medicine of the Roman University, has bestowed steady attention on medical jurisprudence, and has put forth a first instalment of his studies, entitled "Delle Malattie simulate, e del modo di riconoscerle e scoprirne la frode" (On pretended Maladies, and on the mode of recognising them and detecting their fraud). For the ability shown in this treatise, and for other evidences of medico-legal skill elicited by the Committee of Examiners of the University of Naples, Dr. De Pedys has been unanimously appointed Professor of Legal Medicine in that seat of learning. Commenting on his appointment, an Italian contemporary says that his treatise "Delle Malattie simulate"—a volume of 450 pages—is a unique book on the subject in Italy, and that its author, in his new sphere of

Digitized by Google

professorial work, may be expected to raise the subject of his lectures from the decrepitude into which it has fallen in the schools throughout the peninsula.

FROG'S SKIN TRANSPLANTATION.

SOMETIMES slowly healing wounds with feeble granulations are made to increase their activity in the direction of cicatrisation by transplanting minute fragments of epidermal tissue containing some of the cells of the rete Malpighii on the healing surface. O. Petersen has successfully used the skin from the back of a frog. The slowly cicatrising wound was situate on the back of the neck of a man and had resulted from excision of a malignant pustule. A piece of frog's skin the size of the thumb-nail was washed in a 2 per cent. solution and placed upon blotting-paper, when it was divided into two. The grafts were applied to the wound so that the blotting-paper was interposed between them and the fixing plaster. Two days after the transplantation both fragments of epidermis were found to be adherent. Two days later a fresh grafting was made; the former grafts had become roseate. In a further period of forty-eight hours the pigmentation of the grafts had almost disappeared. The cicatrix resulting after this treatment was found to be of great softness and elasticity. Frog's skin as grafts has been recently employed at some of the London hospitals.

DEATH IN HARNESS.

DR. FRIEDRICH WULFF, a well-known and much-respected St. Petersburg practitioner, while paying a professional visit on the 4th instant, was preparing to examine the patient, when an instrument he held in his hand was heard to drop, and he himself, with the simple exclamation "I feel ill," fell to the ground. Life was found to be extinct. The cause was cardiac disease, which, however, had never but once given him any intimation of its existence, and that was a slight fainting fit about a fortnight previously. He was born in 1829, and had never been seriously ill. He was capable of a large amount of work and required but little sleep, and he died, as he probably would have wished to die, in harness. His medical knowledge is described by the *St. Petersburger Medicinischer Wochenschrift* as encyclopædic, but his favourite branch was surgery, he having held important surgical posts in the Obuchoff Hospital. For many years he was secretary and subsequently vice-president of the Society of St. Petersburg Practitioners, and contributed important papers on tracheotomy, osteomalacia, phosphorus-poisoning, and other subjects, to medical literature.

THE ANTI-VACCINATION DELUSION.

THE opponents of vaccination have lately held their annual meeting. They continue to abuse the most beneficent Acts that were ever passed. It is a curious study to notice the pilgrimage to Paris from every country in Europe and from America of those in danger of hydrophobia to take the chance of safety from a new and as yet unproved kind of inoculation, and the contemporaneous meeting of a few victims of the anti-vaccination craze in Bloomsbury to disparage and denounce the vaccination whose efficacy has been proved to demonstration by the all but absolute immunity of small-pox hospital nurses. Much was made of the freedom of Leicester and other places from small-pox. The test is to come, and then not a few who are now decrying vaccination will either rush off to the vaccination office, as those bitten by mad dogs are doing to M. Pasteur, or pay the penalty of disfigurement or death. After all, small-pox is the schoolmaster that drives people to vaccination and keeps green the fame of Jenner.

THE UNIVERSITY OF LONDON.

WE understand that Mr. Magnus's Committee has drawn up a scheme for reforming the University, but that it will not be ready to lay before Convocation at the annual meeting next month; a special meeting will, however, be called for its consideration late in June or early in July. In the scheme the reference to medical degrees will probably be omitted. At the same meeting Convocation will probably be called on to nominate three Fellows, of whom one may be selected to fill the vacancy in the Senate caused by the resignation of Sir Joseph D. Hooker. The last vacancy was filled by an Arts graduate, so it is now the turn of Medicine and Science to elect a representative. The names of Sir Joseph Lister, Mr. Savory, Dr. Barnes, Dr. Bristowe, and Dr. Wilson Fox have been mentioned as prominent medical graduates, and of Mr. Thiselton Dyer, Mr. Magnus, and Mr. Unwin as graduates in the Science Faculty, from whom a choice might be made; but as Mr. Magnus stood on the Arts side at the last election, he will probably decline to be nominated for Science on this occasion.

PATHOLOGICAL SPLEENS.

DR. YASHVILI describes, in the reports of the Caucasian Medical Society, two interesting cases of pathological spleen. A patient who suffered from malaria was killed by an accident, and the spleen was found to be enlarged, with a closely adherent capsule. In the parenchyma was a collection of pus about the size of a walnut, in the walls of which three osseous lamellæ from one to three centimetres in length were found, all the other organs of the body being healthy. The second case was that of a perfectly healthy man who met with his death by accident. He seems, however, to have suffered at some previous time from malaria. The spleen was found to be diminished in size, being only 7·5 centimetres in length, 3 in breadth, and 1 in thickness. The capsule was membranous, thickened, rough, of a greyish-white colour, and closely adherent to the parenchyma. The latter was of a dark-brown colour, and on section the septa appeared as grey cords and nodes. The author suggests that, as this organ could have been of very little use to its owner, the spleen cannot be an absolutely essential portion of the human economy.

SMALL-POX IN RURAL AND URBAN DISTRICTS.

THE lessening of the death-rate from small-pox in London and other of the larger centres of population is being followed by cases of small-pox in some smaller towns and rural districts. This should put the local sanitary authorities of these districts on the alert. As a rule the advice of the medical officer of health is readily acted on, but in some instances it is ignored or only partly followed. In small-pox it is most important that the advice of the medical officer of health should be taken, and any sanitary authority neglecting to act on such advice incurs a grave responsibility.

"A HOSPITAL MISSION WEEK."

THE suggestions recently made by Dr. Wakley for increasing the amount of the contributions to the Hospital Sunday Fund are being very carefully discussed by a special committee of the Mansion House. One of the chief of these is the holding of a series of meetings in six different parts of London, one daily, in the week preceding Hospital Sunday, at which it is hoped that several eminent speakers would advocate the cause of hospitals. These meetings are to be organised by the hospitals themselves in their respective districts, with

Digitized by Google

the help of the Council of the Hospital Sunday Fund. A great opportunity is here given to the hospitals, which, it is to be hoped, will be heartily used by all hospitals. The staffs of hospitals need to rouse themselves in this matter. The enormous multiplication of institutions making a demand on the liberality of the public put hospitals and their quiet unseen work at a disadvantage. We trust that the hospital authorities will exert themselves to diffuse some evidence of their work in the different districts of London. The churches do their part; but it is reasonably thought that more might be done by the hospitals themselves in asserting their claims, and "the hospital mission week," as Sir Edmund Currie happily called it, will afford the opportunity.

SUPRA-PUBIC LITHOTOMY.

IN an article on Rupture of the Bladder in the current number (April) of the *Annals of Surgery*, reference is made to two instances where this lesion followed the distension of the viscus with fluid. One in the hands of Verneuil, where a gentle injection of only 125 grammes was immediately followed by the bursting of the bladder; and one in which the rupture occurred whilst Guyon was preparing to perform hypogastric lithotomy. The latter had thrown 200 grammes of boric solution into the bladder and 300 grammes of fluid into the rectal balloon, but the vesical globe did not appear. A little more fluid was injected into the bladder, and the hypogastrium was distended for a moment, but then suddenly became flat. Death occurred in twenty-two hours, and the necropsy showed the walls of the bladder to be 8 mm. thick, with an anterior perforation 12 mm. long. It is desirable that instances of this kind should be borne in mind now that the revival of supra-pubic lithotomy, as adopted by Petersen, is under the consideration of surgeons. The possibility of rupture of the bladder or intestine occurring is certainly a new element of risk in connexion with the removal of stones which cannot be treated by crushing.

A COLLEGE OF BARBERS.

THE hairdressers would follow suit to the plumbers and be properly diplomated. By all means; nothing could be better advised on their part, or more consonant with the interests of public health and comfort. It is suggested that they should know something of diseases of the hair and skin. Within due limits this may be wise, but we hope there is to be no repetition of the "dentist" bungle, and that the public will not be in peril of a new invasion of *specially*—that is, imperfectly—informed tinkers for a part of the organism. It is the bane of "progress" that each step "onwards and upwards" involves the development of some additional subdivision of skilled labour. We are of those who believe that sooner or later the rage for specialties must be played out, and that then it will be seen that more has been lost than gained by its ascendancy. By all means let barbers be properly trained, and, if needs be, certificated; but we venture to think that the less a pretence to knowledge of skin and hair diseases is encouraged, the better for the craft and for its customers, the public.

SUTURES IN THE HEART.

A PAPER of Block's communicated to the eleventh congress of the German Surgical Society, 1883, on "Wounds of the Heart and their Cure by Sutures," having attracted the attention of Dr. Philippoff of Kharkoff, he determined to make a series of experiments on dogs and rabbits for the purpose of satisfying himself of the truth of Block's assertion that sutures may, under certain circumstances, be applied to the walls of the heart. Though the Russian observer has not as yet concluded his investigations, he has published a preliminary note in the *Russkaya Meditsina* (No. 11) in which he states that the hearts of some animals will bear transfixion with a fine trocar or a needle, also that wounds of the heart in animals may be cured by means of sutures, but by no means always. He found, too, that the pericardium might be opened in dogs without any serious effects, but that wounds of the large vessels at their exit from the heart were invariably fatal.

INFLUENCE OF ATTITUDE ON THE FREQUENCY OF THE PULSE.

THE pulse is more frequent in the erect than in the recumbent posture. This statement holds good in general when the individual is healthy. Graves showed that some cases of hypertrophy of the heart prevented the change of rhythm, and Jorissenne has demonstrated the same circumstance in pregnant women, in whom the heart also becomes hypertrophied. Now M. P. Longe has found that the same invariability of the pulse-rate sometimes obtains during the period of menstruation. There was no hypertrophy of the heart in the cases investigated by M. Longe, but the arterial tension is said to have been higher than usual. It may be that increased arterial tension is the real cause of the phenomenon of invariability of the pulse-rate.

STAINES FEVER HOSPITAL.

A DEPUTATION from Staines waited upon the President of the Local Government Board on the 15th instant, to bring forward their objections to the erection of a hospital for infectious diseases for the use of their district. The attitude of the Staines rural authority is strange in this matter. Having voluntarily united with the town for the purpose, they selected a site, and, with money borrowed under the sanction of the Local Government Board they of their own accord commenced building operations. Then they suddenly turned round, and, alleging reasons of economy, declined to proceed with the structure, and this notwithstanding the prevalence of small-pox and other diseases needing isolation in their midst. We cannot tell what the decision of Mr. Stansfeld will be in the matter, but it is certain that the attitude taken up by the Staines objectors would be best met by a counter-deputation from the more reasonable part of the population who desire to finish the work that has been commenced.

MULTIPLE HYDATIDS.

A RARE case of multiple hydatids is described by Professors Vinogradoff and Kotovshchukoff in the *Russian Medical Review*. A hydatid about the size of a nut was found in the wall of the left auricle immediately under the pericardium. Three were found in the left lung, one of which was as large as an apple; one was situated in the right lung, and the spleen and the liver both contained hydatids. The results of the post-mortem examination had been to a large extent anticipated by the diagnosis which was made during the patient's life. It may be remarked that the base of the left lung gave a dull note, absence of breath sounds, and vocal resonance.

LADY MEDICAL MISSIONARIES.

THE Society for promoting Christian Knowledge has decided to offer a studentship, at the rate of £75 a year for four years, to assist ladies in obtaining a complete medical and surgical training, with a view to their devoting themselves as medical missionaries among heathen and Mahommedan nations. No more useful or Christian work could be conceived than to supply the women in the East with the medical skill which a complete education can alone give.

Digitized by Google

"THE OUTPUT" OF GRADUATES IN CHICAGO.

A CONTEMPORARY, the *New York Medical Record*, reports the "total annual output" of graduates at Chicago of a "regular" character as 285, to say nothing of the "total output of irregulars," which reached the appalling number of 215, or only seventy less than the "output" of the regulars. And so we read of the "Miami College" graduating a class of forty, the Medical College of Ohio a class of seventy-eight, &c. The *Record* speaks of this prolific production of medical graduates as "a service to the profession"; and our contemporary, the *Journal of the American Medical Association*, speaks with apparent satisfaction of the regulations and provisions for the better education of medical students. We cannot but rejoice at every report of a lengthening of the curriculum, a better standard of preliminary education, and efficient laboratories for practical work in the American schools; but we confess to reading of the wholesale "output" of graduates, as one might read of the output of coals, with something of misgiving. Graduates are rather to be weighed than numbered.

TRICOPHYTON TONSURANS.

IN a note communicated to the Royal Society (Proceedings of the Royal Society, No. 241) Dr. Thin adduces further evidence in support of his conclusion, arrived at from experiments upon tricophyton tonsurans and previously related to the Society, that the fungus is distinct from ordinary fungi, with which it has hitherto been confounded. The additional evidence is derived from cultivations of the fungus in gelatinised beef-juice, in which it will grow when the spores are quite immersed and excluded from air. The contrast with the growth of penicillium is shown by examining cultures of the two fungi at stated intervals; the penicillium is seen to grow with great rapidity, and to develop the characteristic organs of fructification, whilst "the tricophyton mycelium grows steadily and slowly, with no distinct signs of spore formation, and no trace of organs of fructification."

UNQUALIFIED ASSISTANTS.

WE report elsewhere a painful case in which the death of a man at Hoxton seems to have resulted from medicines prescribed by the unqualified assistant of Mr. Money. As the jury have returned a verdict of "gross negligence," which the coroner said amounted to one of manslaughter, we suspend judgment in this particular case. But we are bound to lose no opportunity of expressing our surprise that many medical men should still continue to employ unqualified assistants as they do, leaving them often in complete or almost complete charge of cases. In many instances the assistant is taken for, and understood to be, the principal, and continues to attend till death appears in view and all control of the case is lost.

OPERATIONS IN COUNTRY HOSPITALS.

SENIOR students are often lamentably ignorant of the vast field for improving their knowledge of surgery which exists in many provincial hospitals to which no medical school is attached—a field which as yet is, comparatively speaking, unexplored, and which is certain in the not distant future to receive more attention than has yet been given to it. Such being the case, no apology is needed for publishing a list of operations which were performed on the 17th ult. (the ordinary operating day) at the North Staffordshire Infirmary. They were as follows:—Colotomy, amputation of thigh, gastrostomy, radical cure of hernia, operations for tumours of testicle and hernia, epithelioma of tongue (excision), condylomata, and malignant tumour of leg (resulting, after consultation, in amputation of thigh). This list is one which will bear comparison with that presented at the majority of the hospitals which are frequented by students of surgery, and is one which, we are assured, is not exceptional in the importance and number of the items of which it is composed.

KOCH'S BACILLI IN ADDISON'S DISEASE.

DR. GOLDENBLUM of Dorpat gives in the *Vrach* (No. 11, 1886) an account of a case of Addison's disease occurring in a young man, in which the suprarenal capsules, which were cheesy, contained Koch's bacilli. The other organs of the body, including the lungs, which were emphysematous, were also examined, but no bacilli were found. The suprarenal capsules were immersed in alcohol and sections made, which were stained by Ehrlich's method. A previous case of Addison's disease in which Koch's bacilli were found in the suprarenal capsules was reported in the *Vrach* (No. 1, 1886), but in that case the diagnosis was somewhat less clear, the body not being distinctly bronzed, though a greyish discolouration was noted; there was also tuberculosis in the lung, which did not exist in Dr. Goldenblum's case.

FOREIGN PROFESSORSHIPS.

THE chair of Practical Pharmacy in the Madrid Faculty of Pharmacy has been filled by the appointment of Dr. Don Ricardo de Sádaba y Garcia del Real, supernumerary professor in the faculty. Dr. S. Kostyurin, of the St. Petersburg Military Medical Academy, has been appointed to the Professorship of General Pathology in the University of Kharkoff. Dr. Nikolai Voronzovski, Professor of Operative Surgery in the University of Moscow, has just died, leaving £2400 to found scholarships, and £1000 to found a library for the Medical Faculty.

IN reporting to Colonel Sir Francis Bolton on the composition and quality of daily samples of the water supplied to the metropolis during March, Messrs. Crookes, Odling, and Tidy state that they have analysed 189 samples derived from the mains of the seven water companies taking their supply from the Thames and the Lea, and "the whole were found to be perfectly clear, bright, and well filtered." They add that the condition of the water was in all respects thoroughly satisfactory.

THE death is announced of Señor Don Eugenio Alau, a Spanish physician, who had occupied the posts of Civil Governor in various provinces, of Rector and Professor in the University of Valladolid, Senator of the Kingdom and Councillor of Public Instruction. He received the Grand Cross of Isabella the Catholic, besides being the bearer of many other honours awarded to him for his distinguished services.

WE understand that at the forthcoming festival of the Royal Medical Benevolent College at the Holborn Restaurant on Tuesday, May 11th, the music will be entirely in the hands of members of the medical profession, including such distinguished amateurs as Dr. Lavies, Mr. Critchett, Mr. Hepburn, and others, Mr. Ganz presiding at the pianoforte.

IN reply to a deputation of anti-vaccinationists, Mr. Stansfeld recently stated that he thought it would be useless to expect the House of Commons to accede to the abolition of compulsory vaccination.

IT is stated that Messrs. Vanderbilt Bros. have given a quarter of a million dollars towards the erection and endowment of a clinical building for the College of Physicians and Surgeons in New York.

Digitized by Google

The Times Russian telegrams of April 16th contain information about the Pend-jeh sore which was noticed in THE LANCET of April 10th. This disease is attracting a good deal of attention in Russia. It is now attributed to bacteria in the water of the Murghab valley, and alarm is felt lest an army should be incapacitated by it.

AN Order in Council has been published reappointing, under the provisions of the Medical Act, Mr. John Simon, C.B., F.R.S., and Mr. T. Pridgin Teale, F.R.C.S., to be members of the General Council of Medical Education and Registration of the United Kingdom for a further term of five years from May 23rd next.

ANOTHER of M. Pasteur's Russian patients, the fourth, has, it is announced, died of hydrophobia.

Pharmacology and Therapeutics.

ALETRIS CORDIAL.

WE have received from Messrs. Burgoyne, Burbidges, and Co. specimens of "Aletris Cordial," which is said to be efficacious as a "uterine tonic and restorative." Of this special preparation we have had no experience; but the drug itself, the "Aletris Farinosa," or "Star-grass," of Central America, is familiar enough to all who take an interest in the progress of therapeutical science. The root from which presumably the cordial is prepared has many useful properties, and has long enjoyed a reputation in the treatment of various forms of uterine complaints. A thorough investigation of its medicinal properties is a desideratum.

KENNEDY'S EXTRACT OF PINUS CANADENSIS.

The Pinus Canadensis is presumably the Pix Canadensis or Canada pitch, a resinous exudation from the hemlock or hemlock spruce of Canada and the United States. It is a non-irritating mucous astringent, and is likely to prove useful in catarrh, leucorrhœa, gonorrhœa, and other conditions attended with profuse discharge. It was frequently employed by the late Dr. Marion Sims, and is supposed to be a valuable remedy.

TABLOIDS OF COMPRESSED TRINITRINE.

Trinitrine is the new name for nitro-glycerine, the general adoption of which has been advocated by Dujardin-Beaumetz, Huchard, and other continental observers. Its occurrence in prescriptions is less likely to alarm the susceptibilities of delicate, nervous, or highly-strung patients than the more commonly employed term. The tabloids of compressed trinitrine are made with sugar of milk, which is admirably adapted for the purpose, and dissolves much more rapidly than any of the ordinarily employed excipients. We have made trial of these new tabloids, and find that they answer admirably in cases of angina pectoris, giving prompt relief to the paroxysms of pain. The compound trinitrine tabloids, containing, in addition to nitro-glycerine, nitrite of amyl, menthol, and capsicum, constitute a valuable preparation, and will in all probability speedily replace the officinal formula.

QUEBRACHO BLANCO.

The origin and therapeutic value of the barks known under the name of Quebracho blanco form the subject of an interesting communication by Charles Eloy and Henri Huchard in the *Archives de Physiologie*, published this month. Though long in common use in South America, it was only as recently as 1878 that Penzoldt of Erlangen employed it in Europe. Since that period, however, several physicians and pharmacologists have studied the effects it produces, and the general agreement that has been obtained shows that its effects are constant; and there can be no doubt that a new and valuable drug will by its introduction be added to our materia medica. Botanical investigation has demonstrated that the bark named Quebracho really belongs to four different plants—namely, the Aspidosperms, Quebracho, or Quebracho blanco, belonging to the natural order Apocynaceæ, the wood of which is very hard and furnishes the active principles of which mention will presently be made; the Lexopterygium Lorenzii or Quebracho Colorado of the natural order Terebinthinaceæ, the bark of which is rich in tannin; the Iodina rhumbifolia or Quebracho flogo, of the family of Ilicineæ; and, lastly, the Macharium fœtidum or Quebracho tipa, of the natural order Leguminoseæ. The two last are little known, and perhaps possess no medicinal value. The best barks come from Pilciao, and are obtained, like those furnishing quinine, from the smaller branches of the trees. The active principles hitherto obtained from them are aspidospermine, $C_{22}H_{30}N_2O_2$, considered by some to be identical with paytine; quebrachine, $C_{21}H_{26}N_2O_2$; aspidospermatine, $C_{22}H_{23}N_2O_2$; hypoquebrachine, aspidosamine, and quebrachamine. The most remarkable influence exerted by the bark, as well as by these substances, and especially by quebrachine and aspidospermine, is their power of lowering the temperature of the body. The administration of seventy-five milligrammes per kilogramme of body weight to a rabbit caused the temperature in the rectum to fall to 3° C. in the course of forty-nine minutes. This depression of temperature is associated with some remarkable alterations in the respiratory function. The first effect is to render the respirations deeper, but not more rapid; then after the lapse of a quarter of an hour the respirations become more rapid in the proportion of 11 : 12 in the rabbit and 10 : 11 in the dog, an effect that is persistent for a long time. When larger and toxic doses are given the respirations become arhythmic and shallower till death occurs. Quebrachine is more active and more poisonous than aspidospermine, whilst its antithermic properties are still greater, a diminution of temperature amounting to from 5° to 7° C. having been observed in ten minutes. Other symptoms observed in dogs, when moderate doses of five centigrammes were given by the mouth, were, in the course of a few minutes, convulsions, paralysis of the hinder limbs, and tumultous action of the heart, which lasted for an hour and a half. When recovery took place M. Petrone observed reflex modifications of sensibility, mydriasis, and congestion of the auricle of the ear. Eloy and Huchard, however, did not perceive any mydriasis. In their experiments pure aspidospermine produced spasms of the hind limbs and trembling of the muscles, passing, when the poison was not eliminated, into paralysis, but when smaller doses were given terminating in recovery. The sensibility remained intact. The frequency of the cardiac pulsations fell from 156 to 126, the vessels of the auricle becoming at the same time intensely reddened. In some instances the galvanic excitability of the phrenic nerve was observed to be augmented both with aspidospermine and with quebrachine. Both substances caused hyper-secretion of the kidney, of the glands of the intestines, and of the salivary glands. It is clear from these facts that in quebracho bark proximate principles exist which may prove of great value in the treatment of disease. It has been recommended in dyspnœa, both of pulmonary and of cardiac origin, and has been found to possess some, at least, of the value assigned to it by the American aborigines, who regard it as febrifuge, anti-diarrhœal, and diuretic.

EL KELLAH.

This plant, the Ammi visnaga of botanists, has furnished M. Moustapha with a ternary compound, kelline, having narcotic properties, and in animals inducing vomiting, with paralysis of the hinder extremities, irregularity of the heart, and slowing of the respiration. The fruit has been used therapeutically in the proportion of 6 to 8 per cent. as a tonic and astringent gargle in cases of stomatitis, dental caries, and gingivitis. In daily doses of 150 grammes, the decoction of the seeds has been employed for rheumatism. An ointment made by triturating the seeds of kellah with oil or a fatty substance serves for frictionising the joints and articulations. A decoction of from 18 to 20 grammes of the seeds in 160 grammes of water is said to be efficacious in

Digitized by Google

gravel. Finally, the decoction is stated to be a febrifuge, and the leaves are also employed in the preparation of cataplasms.

HOPEINE.

The investigations of Dr. Paul appear (*Pharmaceutical Journal*) to prove that hopeine is an artificial product, which has been manufactured by the admixture of morphine and cocaine. At all events, these two alkaloids were detected in several specimens analysed by him. And as the sources of such alkaloids are of widely different botanical origin, the above conclusion appears probable.

THE FIFTEENTH CONGRESS OF THE GERMAN SOCIETY FOR THE ADVANCEMENT OF SURGERY.

THIS Congress was opened on the 7th inst. at Berlin, in the Aula of the University, the attendance of Berlin physicians and guests being very numerous. Amongst those present were noticed Volkmann, Czerny (Heidelberg), Mikulicz from Krakow, Schœde from Hamburg, Roser from Marburg, Gurlt, Küster, Israel, Bergmann (all four from Berlin), Kœnig from Gottingen, and Thiersch from Leipsic. The Vice-president, von Volkmann, opened the meeting, expressing his regret that the President, the highly honoured von Langenbeck, was prevented by illness from being present at the Congress. As an acknowledgment of the high services of the veteran surgeon on behalf of the Society, he proposed that they should elect him as honorary president. The proposal was accepted with acclamation, and the resolution telegraphed to von Langenbeck at Wiesbaden. Sir James Paget and Sir Joseph Lister in London, who at the last Congress were elected honorary members, sent communications expressing their sense of the honour shown them, and requested that their acknowledgments might be communicated to the Society. The Society has lost several prominent members through death, amongst them being Professor Uhde of Brunswick, Vogt, surgeon at Greifswald, Starke of Berlin, and Burow of Kœnigsberg. All were highly esteemed on account of their personal qualities and extensive knowledge. Five members have left the Society and seventeen have entered, so that the Society now numbers 359 members. Von Volkmann was elected chairman, von Bergmann vice-chairman, von Gurlt (from Berlin) resident secretary, and von Küster resident treasurer. Herrn Schœnborn from Kœnigsberg, Thiersch, Kœnig, Roth from Dresden, and Esmarch of Kiel complete the committee.

The course of addresses was opened by Professor Kraske of Freiburg with a discussion on the Etiology and Pathogenesis of Acute Osteo-myelitis. Roser, Mikulicz, Fraenzel, and others took part in this discussion.

Afterwards Rinne, from Greifswald, spoke on the Drainage of Abscesses of the Abdomen.

The next address was by Professor Rosenbach, from Göttingen, on the Etiology of Traumatic Tetanus in Human Beings. Hitherto, the author observed, no satisfactory explanation has been forthcoming of this affection. The relation of the wound to the tetanus could not be direct. Wounds containing foreign bodies, wounds attended with gangrene, and gunshot wounds in the upper and lower thigh show principally an inclination to cause tetanus. The experiment of injecting blood and matter of tetanised beings into dogs has given negative results, the dog remaining entirely unaffected; but results have been obtained with rabbits, guinea-pigs, and mice. Curiously enough, the inoculation of these animals with earth caused tetanus, with symptoms quite equal to those of traumatic tetanus in man and the horse, the latter often dying of the disease. From a man who, in consequence of frozen feet, had died of tetanus, the speaker received, through repeated inoculation on guinea-pigs and mice, material for microscopic examination, and discovered in it those fine bristle-like split fungi which Nicolaier received from the cases inoculated with garden earth. The fungus is a bacillus, and is most likely the cause of tetanus through the secretion of a sort of strychnine poison.

After an adjournment for refreshment, an address by Dr. Landerer from Leipsic followed on Transfusion and Infusion. The speaker said that the use of a solution of common salt, recommended by Kronecker and Sander, had secured a little better result than had attended the employment of blood. Nevertheless this method was also unsatisfactory, because the introduced liquid contained scarcely any nutritive material, and consequently, after a short revival of the patient, his death could not be prevented if more than 4½ per cent. of the body weight in blood had been lost. He had therefore employed a mixture of one part of defibrinated blood to four parts of the solution of alkaline salt. With this he had obtained good results, even if more than 5 per cent. of blood had been lost. At the suggestion of Professor Ludwig, of Leipsic, a solution of alkaline salt mixed with 3 per cent. of common cane sugar was then used. Trials on animals showed that this operated well, even with a loss of 6½ per cent. of blood; after a fortnight the loss of blood particles was replaced. Various causes were given in explanation. First, the blood particles keep better in a solution of sugar than in a solution of salt; then, again, sugar draws great quantities of moisture out of the parenchymatised webs, and procures in this way nutritious powers for the thinned blood; sugar is in itself nutritious and burns very quickly, therefore quickly brings warmth to the body, increases the pressure of blood, &c.

At the meeting on the 8th inst., a discussion resolved on at last year's Congress concerning Operations on Stone in the Bladder was held. In was opened by Kœnig from Göttingen, and continued by von Bergmann, Trendlenburg, von Volkmann, Schœde, Fürstenheim, Schœnborn, Sonnenburg, Israel, Gussenbauer, Küster, Löbker, and Petersen.

It was decided to bring forward for discussion at the next Congress Operations on Obstruction of the Bowels and on Peritonitis and Perforation of the Gut.

UNQUALIFIED ASSISTANTS AND BRANCH DISPENSARIES.

ON Friday, the 16th inst., Mr. George Collier, Deputy Coroner for East Middlesex, held an adjourned inquiry at the Shoreditch Town Hall relative to the death of Henry Hibbard, aged fifty-four, of 45, Bookham-street, Hoxton, who had been in the employ of Messrs. Barron, Harvey, and Co., wholesale druggists, as warehouseman, for a period of twenty-six years.

Mrs. Ellen Hibbard deposed that on Saturday, March 27th, deceased did not get up, and complained of want of sleep. He sent her to Mr. Money's surgery for a bottle of composing mixture, he having had one bottle before. She went as directed, and deceased took the medicine. He got no sleep, and on the Sunday he had another bottle. On the Monday he was worse. She then went to the surgery and asked the doctor to call and visit the patient, which he did, and told her to call for the medicine, telling her it would be two doses, which were to be given in a little stout. She fetched the medicine and gave it as directed—one dose when she got home (about 3.15 in the afternoon), and the other at 6 o'clock, as the first did not have the desired effect. Shortly after taking the second dose her husband became insensible. She went for the doctor, and Mr. Money himself came. Up to that time she thought that she had been dealing with a properly qualified man, but found then that it was the assistant who had been prescribing for her husband. Her husband died at about 8.15. On Tuesday Mr. Money called and told her it would be all right; that a mistake had been made, as the bottle contained three doses instead of two, and he would have to communicate with the coroner before giving the certificate. He took the bottle away with him. The bottle produced (an ordinary six-ounce medicine bottle) was similar. She did not read the label, although she could read, as she received such plain instructions. She was sure she was told to give the second dose about two or three hours after the first. The assistant admitted that she had followed his verbal directions.

Absalom William Head, 29, East-road, in reply to the coroner, said he was possessed of no medical qualifications. He had been assistant to Mr. Money for thirteen months, but he had been connected with the profession twenty-six years. He had sole charge of this dispensary. Witness first saw the deceased on the 29th ult., when he was delirious. He was quite positive he told Mrs. Hibbard that four hours were to elapse between the doses. He did not tell her there

Digitized by Google

were three doses. He found he had got no two-ounce bottles, so he made three doses, and wrote on the label, "One-third part to be taken every four hours in half a glass of stout if relief is not procured."

Mr. Money gave evidence on the last occasion that the death was due to narcotic poisoning. He was now recalled.

The Coroner: If you had auscultated the case should you have had any difficulty in arriving at the conclusion that the heart was diseased?—Mr. Money: I say emphatically (I was present at the post-mortem) that the fatty degeneration of the heart I witnessed was such as could not be determined by the stethoscope.—The Coroner: You concur generally as to the correctness of the post-mortem?—The Witness: Oh, certainly.

Mr. Bagster Phillips, divisional surgeon, H Division, 2, Spital-square, said, in accordance with the request of the coroner, he had made a post-mortem examination of the deceased. Mr. Money and Mr. Head were present. He made the examination on the 3rd inst. As to the general appearances of the body, he said it was fast decomposing. It was well nourished. There were no marks of violence. The coverings of the brain—skin and scalp—were very congested, as was also the substance of the skull. The membranes of the brain were loaded with blood and somewhat thickened, and not healthily transparent. The substance of the brain was venously congested and of a fair consistence. The lungs were loaded with blood. The heart was large, flabby, and the degeneration had taken place somewhat extensively, but was not in a very advanced stage as regarded the fibres themselves. The walls were very thin, especially of the ventricle. The stomach was very large and almost empty. The whole structure of it was degenerated, denoting that the deceased was a very dyspeptic subject when alive. The liver did not indicate intemperate habits so much as the stomach. He should give the opinion, from the condition of the stomach and liver, that the man was of intemperate habits, not to say a habitual drunkard, but a man who indulged in "nips." Spleen, normal; kidneys fairly healthy for a man in such a state of health. Intestines comparatively healthy, but showed the man had not taken much food very recently. His opinion of the cause of death was failure of the breathing power—asphyxia. He should say that death was caused by the medicine acting upon a subject very prone to the action of such medicine in a deleterious way.

The Coroner: Supposing you had been called into a case of this kind, would you have had any difficulty in arriving at a conclusion that the patient had a weak heart?—Mr. Phillips: No, I think not.—The Coroner: Do you think, under the circumstances, the remedies prescribed were proper?—Mr. Phillips replied that this was a very difficult question to answer directly. He should prefer to say that he should have hesitated very much to give such a dose as indicated by the prescription, and there were other remedies he should have chosen rather than chloral and morphia, with a knowledge of the state of the heart of the deceased. He would give it as his opinion that it was unadvisable to give those remedies in such a state as the man was. Had these not been given, the man would not then have died.

The Coroner summed up the evidence and carefully explained the law of manslaughter to the jury, and then observed: I will leave the case in your hands, merely just casually remarking, first of all, upon what I must discountenance, namely—the prevailing practice (for it prevails to a large extent in this neighbourhood) of setting up these dispensaries and putting unqualified assistants in them. If there had been no dispensary of this kind in the neighbourhood, this man's death would not have occurred. There is no reason why, if a man's practice is extending, he should not put up a branch establishment, and attend the poor for a small fee. But I must say these dispensaries are commenced with a deception on the public. In the first place, the public are attracted by the smallness of the fee they have to pay; and, in the second place, they believe they are being treated by the qualified practitioner whose name usually appears upon the door. At the large hospital in the neighbourhood—the London Hospital—all the house-surgeons are obliged to be qualified. Yet here is a system by which any man can come forward and engage himself, and practise upon the public just as he likes. Unless something happens, and he brings himself within the criminal law, he goes on with impunity. Under the circumstances, I think I may call it a most iniquitous system, one that should be put down, and one I always endeavour to put down when opportunity offers.

The jury retired to consider their verdict, and shortly afterwards they returned, and the foreman said their verdict was: 'Gross negligence against the assistant."—The Coroner: That amounts to a verdict of manslaughter.

The assistant was thereupon taken into custody on the Coroner's warrant.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6100 births and 3585 deaths were registered during the week ending April 17th. The annual death-rate in these towns, which had steadily declined in the preceding four weeks from 29·3 to 20·1 per 1000, was last week 20·3. During the thirteen weeks of last quarter the death-rate in these towns averaged 24·4 per 1000, and corresponded with the mean rate in the first quarters of the ten years 1876-85. The lowest rates in these towns last week were 14·4 in Wolverhampton, 14·7 in Sunderland, 15·3 in Birkenhead, and 15·5 in Cardiff. The rates in the other towns ranged upwards to 25·2 in Plymouth, 25·3 in Portsmouth, 27·1 in Manchester, and 32·3 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 359 and 363 in the preceding two weeks, were 367 last week; they included 140 from whooping-cough, 114 from measles, 43 from diarrhœa, 26 from diphtheria, 23 from "fever" (principally enteric), 21 from scarlet fever, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Hull and Leicester, and the highest in Birmingham, Blackburn, and Portsmouth. The greatest mortality from whooping-cough occurred in Plymouth and Salford; and from measles in Oldham, Bolton, Blackburn, Birmingham, and Portsmouth. The 26 deaths from diphtheria in the twenty-eight towns included 17 in London and 2 in Liverpool. Small-pox caused but one death among the residents of London and its outer ring, and not one in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 8, 11, and 13 on the preceding three Saturdays, had further increased to 16 at the end of last week; 6 new cases were admitted to these hospitals during the week, against 4 and 3 in the previous two weeks. The Highgate Small-pox Hospital contained 3 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 917 to 348, were last week 362, and were 105 below the corrected weekly average. The causes of 76, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Bradford, and Wolverhampton. The largest proportions of uncertified deaths were registered in Halifax, Hull, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined in the preceding four weeks from 27·9 to 21·2, further fell to 20·5 in the week ending April 17th, but exceeded by 0·2 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·6 in Greenock and 16·2 in Aberdeen, to 22·8 in Glasgow and 24·5 in Perth. The 507 deaths in the eight towns showed a further decline of 17 from the numbers returned in the preceding four weeks, and included 10 which were referred to whooping-cough, 9 to diarrhœa, 8 to measles, 4 to "fever" (typhus, enteric, or simple), 2 to diphtheria, 1 to small-pox, and not one to scarlet fever; in all, 34 deaths resulted from these principal zymotic diseases, against 62, 46, and 39 in the preceding three weeks. These 34 deaths were equal to an annual rate of 1·4 per 1000, which was 0·7 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 29, 14, and 11 in the previous three weeks, further declined last week to 10, of which 8 occurred in Glasgow and 2

Digitized by Google

in Aberdeen. The 9 deaths attributed to diarrhœa also showed a decline from recent weekly numbers, and included 3 in Glasgow and 3 in Aberdeen. The 8 fatal cases of measles, however, showed an increase; 7 were returned in Edinburgh. Two of the 4 deaths referred to "fever" occurred in Paisley, and the fatal case of small-pox in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding four weeks from 204 to 109, rose again last week to 122, but were 9 above the number returned in the corresponding week of last year. The causes of 61, or 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had steadily declined in the preceding four weeks from 40·5 to 33·0 per 1000, further fell to 25·0 in the week ending April 17th. During the thirteen weeks of last quarter the death-rate in the city averaged no less than 33·5 per 1000; the mean rate during the same period did not exceed 24·8 in London and 20·0 in Edinburgh. The 169 deaths in Dublin last week showed a further decline of 54 from the numbers in recent weeks, and included 16 which were referred to the principal zymotic diseases, against 18, 15, and 16 in the previous three weeks; 5 resulted from whooping-cough, 3 from "fever" (typhus, enteric, or simple), 3 from diphtheria, 3 from diarrhœa, 2 from scarlet fever, and not one either from measles or small-pox. These 16 deaths were equal to an annual rate of 2·4 per 1000, the rates from the same diseases being 2·3 in London and 2·0 in Edinburgh. The fatal cases of whooping-cough, which had been 6 and 11 in the preceding two weeks, declined again last week to 5. The deaths from "fever" and scarlet fever corresponded with the numbers in the previous week, while those from diarrhœa and diphtheria exceeded the numbers in recent weeks. The 3 deaths referred to diphtheria, were, with the exception of one in February, the first deaths from this disease recorded in the city since the beginning of this year. Three inquest cases and two deaths from violence were registered; and 44, or more than a quarter of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable further decline from the numbers in recent weeks. The causes of 20, or nearly 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major John Butler Hamilton, M.D., to be Brigade Surgeon, vice Oliver Codrington, M.D., retired; Surgeon-Major Franklin Gillespie, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Daniel Charles Grose Bourns is placed on temporary half-pay, on account of ill-health; Surgeon-Major Ulick Albert Jenings, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major James Henry Ussher, M.B., half-pay, has retired from the Service, receiving a gratuity.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon William Henry Patterson, to the *Sapphire;* Surgeon Clement Alsop, to the *Cockchafer;* Surgeon George Hamilton H. Symonds, to the *Merlin;* and Surgeon Timothy Joseph Crowley, to the *Espoir.*

YEOMANRY CAVALRY.—Lancashire Hussars: Damer Harrisson, Gent., to be Surgeon.

ARTILLERY VOLUNTEERS.—1st Sussex: Acting Surgeon Henry Algernon Hodson resigns his appointment.

RIFLE VOLUNTEERS.—1st Cumberland: Surgeon C. S. Hall is granted the honorary rank of Surgeon-Major.—1st Forfarshire: The undermentioned Surgeons are granted the honorary rank of Surgeon-Major:—David MacEwan and Alexander Campbell. These gentlemen were in our last issue erroneously stated to be members of the 3rd Volunteer Battalion (the Essex Regiment).—2nd Volunteer Battalion, the Royal Welsh Fusiliers: Acting Surgeon H. L. Davies resigns his appointment.—2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon H. B. Wood is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

INJURY TO GENERATIVE ORGANS IN LATERAL LITHOTOMY.

To the Editor of THE LANCET.

SIR,—Will you allow me to amplify the remarks I am reported (in your last issue) to have made at the Clinical Society on the above subject?

In referring to the asserted danger of wounding the ejaculatory duct on one side, or even on both sides, during the performance of lateral lithotomy, as taught by Von Langenbeck and accepted by other authorities, my object was to elicit definite information on the subject. But I did not succeed. On the contrary, Mr. Walsham, in reply to my question, said he had no evidence to adduce, and Mr. Bryant and Mr. Hutchinson, at the close of the meeting, both told me that they had not met with any cases in practice. Nor have I.

It would be really interesting if this question could be definitely settled, as it readily may be, by recording any cases on which the doctrine rests and submitting them to scientific scrutiny. In any suspected cases, evidence must be forthcoming that the results are really due to the lithotomy and are not congenital malformations.

I presume that we should expect the danger to be greatest in those operated upon in early childhood, when available space is limited, and while the tissues are soft and easily torn; and that non-development of the testis or testes would be the lesion to look for. Rupture of or injury to the ejaculatory ducts or vas deferens is inflicted (if at all) by the laceration which follows the extraction of a large stone, rather than by the surgeon's knife; large stones are usually found only among old persons. On the other hand, secondary changes in the generative apparatus are less likely to follow in old persons, and less likely to attract attention. In young children, however, subsequent want of development of the affected organ would be more certain to follow; it would most assuredly attract the attention of parents, and so come within professional cognizance.

It is desirable that the truth on this matter should be known. If the danger exists, it will be a patent argument in favour of the supra-pubic operation, and one, by the way, not advanced by its advocates in the recent discussion at the Royal Medical and Chirurgical Society; while, if the danger is imaginary, surgeons will be glad to know it.

I am, Sir, yours faithfully,

London, April 19th, 1886. ROBERT WM. PARKER.

ZINC PLATES IN IRON BOILERS: A CAUTION.

To the Editor of THE LANCET.

SIR,—During a recent voyage to Queensland, in the capacity of ship surgeon in a new steam-ship recently built in Glasgow, an outbreak of colic occurred towards the conclusion of the voyage, attacking certain firemen, sailors, and others, which, assuming more or less an epidemic character, seemed to suggest some special cause for its occurrence. In one case the cramps were so severe as to suggest the presence of cholera poison, an idea which was fostered from the circumstance of the report of the outbreak of "cholera" on the *Dorunda* steamship, one of the Queensland Government mail and emigrant line, which had preceded us at Batavia. Presumably actuated by this idea, one of the crew, an old fireman, on his own responsibility and without my knowledge, took one of the men then ailing—the "donkey-engine" man, whose symptoms were severe—into the watercloset, stripped him naked, and, having procured a bucketful of hot water into which he placed a handful of mustard flour, gave the man therewith a vigorous sponge bath. I subsequently got the patient into his bunk, and, placing turpentine stupes on his abdomen, gave him a dose of castor oil and laudanum; the latter a line of treatment which I had found serviceable in previous cases, with beneficial results, so that in a day or two he was fit for work again. In addition to the colic there was also noticeable, during the latter part of the voyage, a great tendency to suppuration, boils and the like,

Digitized by Google

where the skin was scratched or otherwise broken, or even where exposed to the irritation of the clothing long wet with salt water. I should say that up to Batavia and beyond we had been using Loch Katrine water, supplemented by a small supply from Plymouth, both being of unquestionable quality. Any probable intention of taking in a further supply from the port of Batavia, where we coaled, was at my suggestion entirely abandoned by the captain, especially as he had there been apprised, by telegram, of the occurrence of cholera on the *Dorunda* some time after leaving the port at which we then were; and, in fact, a message had been sent prohibiting the entrance of vessels proceeding to Queensland ports within the harbour of Batavia in consequence of that circumstance, but it arrived too late to admit of the captain's compliance with the order. We were then under the necessity of condensing the sea-water, a task which the chief engineer readily undertook.

In view of the epidemic character of the symptoms of colic and abdominal cramps, one of the engineers suggested the possibility of the zinc plates which were fixed in the "donkey boiler"—whence our supply of water for drinking purposes was condensed—in order to prevent the corrosion of the iron as being the cause—an idea, I may say, not favourably received by some others. I thought it advisable, however, to procure a sample of the water in order to test it for the presence of zinc, which I accordingly did. I may say that the weather was hot and wet, and the quantity of water consumed, especially by the poor firemen in their arduous toil, in the shape of meal and water, was unusually large. In the process of galvanising, or coating iron with zinc, the latter metal not only acts as a varnish or protective, but becomes oxidised, as you are aware, before the iron is so acted upon, even though its surface be exposed. L. L'Hote, in "Comptes Rendus," says: "As to the inquiry if zinc free from any foreign metal decomposes water either on boiling or in presence of dilute sulphuric acid, experiment proves that such is not the case. Pure zinc heated with distilled water in a flask, so arranged as to receive the gases over mercury, gives off no hydrogen on prolonged boiling, nor is it attacked by dilute sulphuric acid. The presence of iron in the proportion of 3 to 5 in 100,000 enables it to decompose water. Traces of arsenic and antimony have the same effect."

On my return home, and having leisure to prosecute the inquiry, I find, on evaporating a portion of the water in question and testing it, there is decided evidence of the presence of zinc. Hence it will, I think, appear evident that the presence of zinc plates in iron boilers used for condensing water for human consumption is fraught with danger to the health, if not, indeed, to the life, of those consuming the water for any length of time. Although in the case of the ship in question, intended for the coasting trade of Australia, it is probable that condensed water will not often be used, and although unhappily the quality of the water obtainable at some of the ports on that coast is not of the best, and will not suffer from boiling before being drunk, yet the subject, embracing also the very general use of galvanised iron under similar circumstances, I think you will be prepared to admit, is well worthy the attention of those concerned, and, as in cases similar to the above, of investigation by the Board of Trade.

I am, Sir, yours faithfully,

JOHN WARD, M.D.,
Ex-Medical Officer of Health.

Sutton Coldfield, Birmingham,
April 12th, 1886.

LAW AND LUNACY.

To the Editor of THE LANCET.

SIR,—As a forcible illustration of one of the social phases of the deleterious consequences arising from the recent prosecutions of medical practitioners for giving certificates of insanity, I venture to forward to you a few extracts from a letter my wife received from a lady friend this morning. They appear to me to be so brimful of materials for reflection, alike to doctors, lawyers, and the general public, that they ought to be made known. I give the extracts in the lady's own words, for although the language she employs is simply that of a friendly letter, it seems to me to be quite telling enough, and will possibly be all the more impressive by reason of its very simplicity. I suppress, of course, the name of the writer, and as the extracts from her letters are forwarded to you without her knowledge, I hold myself responsible for them. They are as follows:—

"My husband's illness from overwork has taken a very serious turn, after apparent complete restoration. He has some form of brain mischief which makes him believe that he is very rich, and he has been buying everything he fancies for a year past, including land, and entering into terrible expense connected with railway-making. He will take no advice, and I have been consulting doctors in vain for months, hoping to get help to protect him from those preying upon him. But, alas! from the state of the law and the fears medical men are in of the consequences, it has been all in vain, though they admit the need. All his property is involved now; our home is sold up, and our pretty things have all been ruthlessly squandered by a forced sale. I see no end of my troubles, for Mr. —— considers himself still as rich as ever, and is so angry at me for doubting it that I hardly dare go to him. At present I have no home to go to, except to one of his country farm-houses, where he had furnished a part for ourselves."

These extracts are, I think, sufficient to show how recent actions against alienists is beginning to react against the general public, and when viewed in association with Lord Shaftesbury's sad suicide prove that the present state of the Lunacy Law as regards the responsibilities of medical men in signing certificates requires immediate emendation.[1] For while Lord Shaftesbury destroyed his own life, here, in the above-mentioned case, the gentleman destroys the means not only of supporting his life, but that of his family. Every medical man knows how often a few months of well-regulated restraint will suffice to cure an attack of monomania, and how that the individual after recovery may enjoy many long years of comfort and happiness. He equally knows that it is exceedingly rare for any of these cases, except during the incubation period, to possess either sufficient mental power or moral strength to voluntarily place himself under restraint, while the medical treatment of monomania involves quite enough of anxiety without having the additional terrors of the law superadded to it. If Lord Shaftesbury's and the above-described case be not examples of true insanity, my notions of mental disease and moral responsibility, I fear, require important revision.

I am, Sir, faithfully yours,

GEORGE HARLEY, M.D.

Harley-street, Cavendish-square.

THE PERILS OF SUBCUTANEOUS MEDICATION.

To the Editor of THE LANCET.

SIR,—Having just heard from Dehra-Dûn to the effect that my old friend and quondam companion in some Himalayan rambles, Frederick Wilson, Esq., better known as "Shikari" Wilson, died at Mussoorie in July, 1883, of what would appear to be an over-dose of morphia, subcutaneously injected, I wish to take this opportunity of calling attention to the subject, and of intimating at the same time that two such cases of this description have occurred within the sphere of my own individual cognisance. I am precluded by personal or professional reasons from entering into any details respecting these, and I merely alluded to them here to enable me to offer it as my opinion—an opinion which, as you, I think, know, is based on something better than books—that this form of poisonous drug administration is fraught with the greatest danger in that most weakening or worrying malady—frequently recurring or chronic, suppressed, or systemic—gout.

As regards the case of my poor friend, and making all due allowance for the feelings or the exaggeration of a son, the circumstances under which he succumbed are briefly as follows:—"He had just returned (says my informant) from Gungostre — the source of the Ganges—suffering, as usual, from his old enemy the gout. As the pain became intense, —— was called in, and he carelessly injected an overdose of morphia, for my poor father never recovered from the deep sleep it produced, but died about three hours after the injection." And had the Emperor Charles V. or the great Earl of Chatham, who were both undoubtedly victims to this disease, been similarly treated during any of their paroxysms, the history of the Spanish Armada or of the French fleet

[1] This necessity has already been represented in a letter signed "General Practitioner," published in THE LANCET of March 6th last.—ED. L.

Digitized by Google

under Conflans might have had to be written in characters different from those of Mottley and Carlyle. "A Yorkshireman from Wakefield, as Colonel Markham described him in his 'Shooting in the Himalayas' (p. 19), fortune in his early life led him to India (in the 11th Light Dragoons); his impaired health sent him to Landour, whence he took a journey in the hills. Returned to England, he was unable to forget the life he led in the Himalayas, which had for him an irresistible charm. Not being overburdened with money, he worked his passage out to Calcutta, and walked straight up to Meerut, a distance of 900 miles, in thirty days. From thence to the hills was an easy trip, where he has been a resident for several years," and where he recently died, as we have just seen. Similar testimony is borne to his capacity and courage, his courtesy and skill, by Mr. Dunlop, B.S.C., in his "Hunting in the Himalayas," as well as by the editor (said to be Mr. Hume) of that pleasant book, "A Summer Tour in the Himalayas," *passim;* and his name and fame were household words in all "shikari" (hunting or shooting) circles in that district. He was, in a word, one of those God Almighty's gentlemen of whom my great namesake used to say that "they carried the title deeds of their estates in the crowns of their hats." But Frederick Wilson carried something more than these in this receptacle. He carried brains and ability of a high order. He also carried in it such energy and honesty, pluck and perseverance, as no discouragement could suppress or opposition subdue, and the consequence is that he has left behind him a name that will not soon die out in those regions, and a heritage and an independence such as any family might be proud of. He showed me many kindnesses, for which I desire to offer, with your permission, these my best thanks, and to offer at the same time, if you will kindly so allow, this little memorial of our friendship as an R.I.P. for his tomb.

I am, Sir, your obedient servant,

Auriol-road, W., March 21st, 1886. WM. CURRAN.

"THROMBOSIS OF THE CORONARY ARTERY DURING ETHER ANÆSTHESIA."

To the Editor of THE LANCET.

SIR,—The case related by Dr. Moxon in your impression of the 17th inst. is full of the greatest interest, not only to the physician and pathologist, but also to those who are in the habit of administering anæsthetics. The vivid picture with which we have been furnished can leave no doubt in our minds as to the proximate or *secondary* cause of death; but, with regard to the remote or *primary* cause, I would deferentially submit that the evidence is not sufficiently conclusive. The charge brought by Dr. Moxon against the anæsthetic agent is a grave one, and it is in the interests of this agent that I would ask to be permitted to say a few words.

Without wishing to doubt the accuracy of Dr. Moxon's conclusions with reference to the age of the thrombus he describes, I think he will admit that the chronic arteritis met with in the coronary artery might at any time have eventuated in thrombosis. It must be remembered that ether is frequently administered to patients whose arteries are atheromatous to an extreme degree, without any subsequent evidence of thrombosis having taken place during the administration. Surely, cerebral thrombosis and its consequences would be more often observed after ether anæsthesia if Dr. Moxon's explanation of his case be a true one. We should, indeed, expect such untoward results to follow chloroform narcosis in old people with comparative frequency were Dr. Moxon's theories correct; for the low arterial tension often observed under chloroform and the degenerated vascular system so common in old age would be conditions eminently suited for the formation of thrombi in the vessels. I would therefore ask: Might not the thrombosis have had an origin totally independent of the etherisation?

I venture to think that all our energies should be devoted towards restricting the use of chloroform as an anæsthetic, and towards insisting upon the advantages of ether for most cases in which general and prolonged anæsthesia is required. I therefore trust that Dr. Moxon will excuse my calling into question the explanations he has brought forward in reference to his interesting and instructive case.

I am, Sir, yours obediently,

Somerset-street, W., April 19th, 1886. FREDERIC HEWITT.

DEATH FROM ETHER.

To the Editor of THE LANCET.

SIR,—In the very interesting account given by Dr. Moxon in your last issue of a case of death from thrombosis of a diseased coronary artery, the ultimate cause of death is attributed to the inhalation of ether for a small surgical operation three weeks previously. The sole grounds on which this statement is made appear to be that the thrombus seemed to be about three weeks old. One naturally wishes for further corroboration of this statement, as thrombosis is not generally considered to be caused by such agency. I have notes of every case of death which could in any way be attributed to the use of ether published during the past ten years, and I have before me as well a report by a committee of physicians appointed by the Boston (U.S.) Society for Medical Improvement, published in 1861, wherein are notes of forty-one cases in which death occurred within a week or two of ether inhalation. In none can I find any note of abnormal blood-clotting, and in many cases there is mention made of the great fluidity of the blood. Among the cases reported by the American committee are no less than three in which ether inhaled by unqualified persons for sport seems to have produced fatal meningitis within a few days. Cases of this kind are reported both from Rouen and Philadelphia.

A pathologist of Dr. Moxon's experience is hardly likely to have made so serious a charge against ether as an anæsthetic without due reason. May I ask him, through your columns, to refer me to any other cases where thrombosis seems to have been caused through the agency of an anæsthetic?

I am, Sir, yours truly,

Leeds, April 20th, 1886. ERNEST H. JACOB, M.D.

SANITARY LEGISLATION.

To the Editor of THE LANCET.

SIR,—Every year the need of further sanitary legislation is becoming more and more pressing, and, in the interest alike of the public health and a minimum of interference with individual freedom of action in sanitary matters, it behoves the members of those professions which are charged with the care of man's physical being and the construction of his dwelling-places to take the subject into serious consideration, in order not only that the necessary legislation may not be too long delayed, but that it may be shaped and directed by those having the greatest knowledge of the questions involved. Two of the chief things to be aimed at in future legislation are: (1) To simplify and bring into one measure the regulations relating to the powers and responsibilities of public authorities; and (2) to increase the responsibility of owners and occupiers in respect of the sanitary condition of their own buildings.

As a contribution towards the solution of the second point I send you the annexed draft Bill, which is now under consideration by a special committee appointed by the Executive Council of the Sanitary Assurance Association.

I am, Sir, yours truly,

MARK H. JUDGE, A.R.I.B.A.

Park-place Villas, W., April 19th, 1886.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SUNDERLAND CHILDREN'S HOSPITAL.

THE annual meeting of the Sunderland Children's Hospital was held last week when the twenty-second report was read, showing that during the past year the number of out-patients treated was 967, and the total number of consultations given was 3006, and 122 children had been treated as in-patients. The total number of patients treated during the year, including in- and out-patients, was 1227. It is stated in the newspaper report that there had been no death among the patients during the year, but probably this is a mistake, as it is not likely that over 1000 sick children could come under hospital observation without some fatality.

"A PETRIFIED GIANT."

Under the above heading a paragraph appears in our local papers, giving a very circumstantial account of some petri-

Digitized by Google

fied human remains found at Consett, in the county of Durham, in a coal mine. One portion found is said to consist apparently of a part of a body, and the upper part of two legs of a "giant," and measure 7 ft. 1 in. in length, and are said to be evidently portions of a body measuring from 9 ft. to 10 ft. high. The petrified body measures from back to front 14 in., and in width 16 in., and was found in the coal 20 fathoms deep. There were also found at the same place pieces of stone which appear to be petrified fish. I give you the newspaper account, but there is no doubt that some vegetable petrifactions have been mistaken for human remains, for I believe that although remains of mammalia have been found in bogs in a petrified or semi-petrified condition, nothing higher than fishes and reptilia have so far been found in the coal measures. So that unless the skull of this "giant" can be produced, I would very much doubt the existence of human fossil remains at such a depth.

TYNE PORT SANITARY AUTHORITY.

At the last meeting of the Tyne Port Sanitary Authority it was stated that during the months of February and March 1976 visits had been paid to vessels by the inspector. The medical officer's (Mr. H. E. Armstrong) report stated that the principal case during the past three months was that of the s.s. *Nederland-en-Orange*, from Bombay with an Indian crew, three of whom died in this port from the effects of the severely cold weather, and three others were reported to have died at sea from the same cause. The vessel had an Indian medical man on board. Mr. Armstrong states that the warming of the between-decks by steam, and removal there of the crews—several of whom were suffering from the cold, and all of whom were exceedingly depressed and melancholy, was advised, and at once carried out, after which the patients improved and the men regained their spirits. Two others of the crew suffered from illness afterwards, due to the previous cold, and were removed to the Newcastle Infirmary.

A NORTH TYNE CENTENARIAN.

Great interest is taken here in the serious illness of Mr. Joseph Saint of Chollerton, North Tyne. Mr. Saint's case is remarkable, but well authenticated as to longevity. He entered on his 103rd year on Feb. 21st, and was then in fair health, but the late severe weather has seriously lowered his vitality, and his medical man fears that his recovery is very doubtful.

DEATH OF MR. MANFORD OF NEWCASTLE.

I regret to close my letter by mentioning the death, on the 16th inst., of Mr. F. W. Manford, a well-known and respected general practitioner of this city. Mr. Manford was a native of Scotland, but had practised here for nearly forty years. He was a L.R.C.S., and F.R.C.S. and L.R.C.P. Edin. (exam.). Mr. Manford was naturally endowed with a very fine constitution, and was thus enabled to get through an amazing amount of work unaided, for, I believe, it was not until quite of late years that he needed any help in his practice; at last he was induced to take a partner; but it was understood that even before then he had made his fortune. He never had any appointments, always refusing offers of the kind, however tempting, saying that it was best for himself and for his patients that all his energy should be devoted to their care. The immediate cause of his death was, I understand, cardiac disease, for which he was attended by Dr. Philipson and his partner, Dr. Scotland. Mr. Manford, who was in his sixty-fourth year, leaves a widow and four children, and his death will be felt by a large circle of friends and patents.

Newcastle-on-Tyne, April 20th.

ABERDEEN.

(From our own Correspondent.)

MEDICAL EXAMINATIONS AND GRADUATION.

THE winter session at Marischal College closed on March 26th. The "professional" examinations began on the Monday following and were finished on Tuesday of last week. The number of candidates presenting themselves for examination was much larger than usual, more especially for the final or "third professional," for which about eighty-five gave in their names. Of these, only thirty-seven satisfied the examiners, the others were rejected, having failed to pass in one or more subjects. The ceremony of publicly conferring the degrees, "the capping," took place on Saturday. Mr. John C. G. Duffus, M.A., and Mr. John D. Thomson, M.A., received their degrees in Medicine and Surgery, with highest academical honours, and Mr. James Galloway, M.A., Mr. W. Milligan, and Mr. James Murray, received their degrees with honourable distinction. Ten gentlemen were promoted to the degree of M.D., eighteen candidates passed the first division of the first professional examination, fifty were declared to have completed the first examination, and nineteen had passed the second.

GRADUATES' SUPPER.

The young graduates had the usual supper on the night previous to the graduation. Several of the professors and members of the medical staff of the Royal Infirmary and General Dispensary were present. Professor Smith Shand presided, and Dr. McKenzie Booth (in the absence of Dr. Angus Fraser) and Dr. Ruxton acted as croupiers.

APPOINTMENT TO THE CHAIR OF PHYSIOLOGY.

It is officially announced that Dr. John MacWilliam, Assistant Professor of Physiology in University College, London, has been appointed Professor of the Institutes of Medicine in the University of Aberdeen. This is an appointment that meets with approval everywhere for many reasons, but perhaps more particularly because while Dr. MacWilliam is a distinguished physiologist, he is also a graduate of the University; and in the past it has often been felt that sons of our *alma mater* were passed over for graduates of other universities, whose claims did not always seem sufficiently strong to form good grounds for the step taken. Dr. MacWilliam graduated in 1880, when he received the John Murray Medal and Scholarship as the most distinguished student of his year.

MEDICAL OFFICER OF HEALTH FOR THE CITY.

At their meeting on Monday, the Town Council unanimously elected Dr. Theodore Thomson medical officer of health for the city. Before proceeding to the election, a proposal to erase Professor Matthew Hay's name from the list of candidates, because he announced his intention of retaining his appointment as professor of medical jurisprudence in the University, was carried by a majority of three votes. One of the conditions as stated in the advertisement is that the medical officer must devote his whole time to the duties of the office. This Dr. Hay could not strictly do, but as his University duties occupy only one hour a day for fifty days in the year, he could have practically given his whole time to the sanitary department. There were ten candidates for the appointment, but Dr. Hay's name having been struck off the list, the result was a foregone conclusion. Dr. Thomson is at present assistant medical officer in the South-Eastern Fever and Small-pox Hospital, London.

THE FREE LIBRARY AND INFECTIOUS DISEASES.

The Public Health Committee had recently before them a report by the sanitary inspector bearing upon the question of the spread of infection by books borrowed from the public library. In his report the inspector suggests that "when patients suffering from infectious diseases are visited by the sanitary officers, inquiry should be made whether any member of the family or any person living in the house is supplied with books from the library; and if it be found that such is the case, the parties should be asked to send the books to the sanitary office for the purpose of being disinfected before being returned to the library." It is proposed also to supply the librarian with a list of the names of families where infectious disease is known to exist, so that he may be able to assist the sanitary department in checking any attempt to evade the law. The committee approved of the report, and authorised the inspector to carry out his suggestions, and send a copy of the report to the Library Committee, who might still further assist the sanitary department by passing a bye-law enacting that books be not lent out to families known to be suffering from infectious disease.

Aberdeen, April 20th.

A LETTER has been received from the Local Government Board approving of the amended plans submitted for the proposed infectious diseases hospital at Widnes. The building is greatly needed in the district, and it will now probably be commenced at once and pushed forward rapidly.

PARIS.

(From our own Correspondent.)

REPORT BY M. PASTEUR.

AT the meeting of the Academy of Sciences last week M. Pasteur read the following report of the results of his anti-rabic treatment at his laboratory in the Rue d'Ulm. "The number of persons so treated amounted up to the 12th inst. to 726, including those who are still undergoing treatment. Of this number there were 688 who were bitten by mad dogs and thirty-eight by wolves, the latter being all Russians. The patients belonging to the first category are, with the exception of the little girl Pelletier, who, it will be remembered, died after a few inoculations, all doing well. More than half of that number have passed the dangerous period. Of the thirty-eight Russians who have been treated and are still undergoing treatment, three have died rabic; the others are doing well, but it is impossible to foresee what may happen to them, as there exists a profound difference between the bites of dogs and those of wolves, the proportion of deaths caused by rabid wolves being at least 82 per cent." M. Pasteur then concluded his report in the following terms:—"The above facts demonstrate (1) that the duration of incubation of human rabies caused by the bite of a rabid wolf is often very short, very much shorter than rabies after the bite of a mad dog; (2) that the mortality after the bites of rabid wolves is considerable if we compare it with the effects from the bites of dogs. These two propositions may be sufficiently explained by the number, the depth, and the seat of the bites caused by the wolf, which so savagely attacks his victim, the attack being often on the head and face. The necropsy of the three Russians who died at the Hôtel Dieu, and the inoculation of rabbits, guinea-pigs, and dogs with the medulla oblongata of the first of the patients who died, prove that the virus of the wolf and that of the dog are sensibly of the same degree of virulence, and that the difference of the rabies of the wolf and that of the dog depends on the number and nature of the bites. These facts induced me to inquire whether, in the case of bites from rabid wolves, the method could not be usefully modified by inoculations in greater number and within a shorter time. The results will be eventually reported to the Academy. In any case, for the wolf in particular, it is good to submit the patient to the preventive treatment as soon as possible. The Russians of Smolensk were six days on their journey to Paris, and presented themselves at the laboratory fourteen or fifteen days after having been bitten. They might therefore have commenced the treatment eight days earlier, and one cannot say what might have been the influence of this modification for the three patients who have succumbed."

THE DISPOSAL OF THE DEAD.

The subject of cremation has been recently discussed at the Chamber of Deputies, and it has been decided that the mode of disposing of the dead will be left optional to the friends of the departed unless special arrangements have been made during the lifetime of the latter. The arguments for and against incineration and inhumation I need not reproduce here, as nothing new was brought forward. I may, however, remark that in response to Bishop Freppel as to the impunity that criminals would enjoy if the bodies were subjected to incineration, M. Blatin, deputy, remarked that the examinations in cases of suspected poisoning could be more usefully carried out before incineration. Even after incineration there are poisons which could be found in the ashes.

VINIC ALCOHOL.

The French Senate offers a prize of from 25,000 francs to 50,000 francs to any chemist who shall discover the best practical method for making researches with the view of ascertaining the toxic principles and impurities contained in "vinic alcohol."

I may mention again that the Hygienic Exhibition is to take place on Monday, May 3rd. Among the exhibitors are the Director of the Paris Municipal Laboratory and M. Pasteur.

Paris, April 20th.

MEDICAL NOTES IN PARLIAMENT.

Lunacy Acts Amendment Bill and the Burgh Police and Health (Scotland) Bill.

IN the House of Lords on the 15th inst. these Bills were read a third time and passed.

The Ventilation of the House.

In the House of Commons on the 19th inst., in reply to Mr. Baumann, Sir H. Roscoe said that the Select Committee on the ventilation of the House had brought under the notice of the proper officer of Her Majesty's Board of Works the desirability of at once carrying out the temporary measures referred to in the interim report of the committee for effectually preventing the passage of sewer-air from the metropolitan main drains into the area of the Palace of Westminster. They had received the assurance of that officer that the proposed work, in his opinion, could be executed before the House re-assembled after the Easter recess, and there was every probability that the improvements would be completed by the time the House met again.

Obituary.

CHARLES BOLINGBROKE COOPER, L.R.C.P.L.

WIDE-SPREAD sorrow is felt in Liverpool on account of the death of Mr. Charles B. Cooper, who was quite recently promoted to the office of house-physician of the Liverpool Northern Hospital, having been previously assistant house-surgeon to that institution. The sympathy with his friends is heightened because his death is looked upon as being largely due to his devotion to his work. For some weeks past he had been suffering from crops of furunculi, and one or two of these on his neck had caused him much pain and annoyance. He had been recommended to take a holiday, but was unwilling to leave his work. On April 6th he became jaundiced; on the 8th his temperature ran up to 105°, and an erysipelatous rash appeared on the neck and shoulders, and he was slightly delirious. Two days later the jaundice had disappeared and the erysipelas seemed to be fading away; but on the 11th it appeared on the face, which next day was much swollen. On the 12th the swelling had increased, the colour of the rash was deeper and dusky, delirium returned, respiration and pulse became rapid, and other symptoms of general blood-poisoning appeared, and terminated fatally on the 14th inst. The deceased suffered four years ago from rheumatic fever, which left him affected with cardiac valvular disease, and this no doubt diminished his chances of recovery.

Mr. Cooper was a young man (aged twenty-four) of handsome appearance and of remarkably prepossessing manners, and his funeral was made the occasion of a display of respect which must have been very gratifying to his sorrowing relatives and friends. Previous to the conveyance of the body to the cemetery a service was held in the hospital chapel, and the chaplain, who officiated, in his address passed a high encomium upon the many praiseworthy features in the character of the deceased. The body was borne to the hearse by six quartermasters of the Beaver line of Canadian steamers, in whose ships the deceased had made several voyages as surgeon. At the cemetery a large number of medical and other friends had assembled, amongst whom were many of the physicians and surgeons of the Northern Hospital, Royal Infirmary, and other hospitals, the chairman and several members of the committee of the Northern Hospital, and a large number of nurses. The body was borne to the grave by two of his colleagues and four other friends, former fellow-students, now house-surgeons in the Liverpool hospitals. The coffin was literally buried in wreaths, sent by numerous friends, and laid on the coffin as it left the hospital by the nurses, under the superintendence of the matron, Miss Huguenin, who had herself officiated as a kind and indefatigable nurse during the last week of the deceased's illness.

VACCINATION GRANT.—Dr. Hodgson, of Workington, has received the Government grant for efficient vaccination in his district.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 19th inst.:—

Barker, John, M.B. Durh., Ruth.
Fletcher, Arthur Augustus, M.B. Melb., Melbourne.
Fraser, Robert Nelson, M.D. Kingston, Westmeath, Ontario.
Halkyard, Alfred Lees, L.K.Q.C.P.I., Knatsford.
Hare, Arthur William, M.B. Edin., Edinburgh.
Herbert, Herbert, L.R.C.P. Lond., Leeds.
Kempster, Felix Charles, L.S.A., Battersea.
Nevins, Arthur Edward, L.R.C.P. Ed., Liverpool.
Packman, Alfred Charles Augustus, Sheffield.
Pain, Francis, L.S.A., Dulwich.
Richards, Thomas, Bristol.
Smith, Frederick Osborne, L.K.Q.C.P.I., Queen's-road.
Strickland, Percy Charles Hutchison, West Dulwich.

Admitted on the 20th inst.:—

Biggam, William, M.B. Durh., Sunderland.
Bonnefin, Fernand Henry, L.R.C.P. Lond., St. Paul's-road.
Clarke, James, Fernandez Howard, L.S.A., Gerald-street.
Coleclough, John Arthur, L.S.A., Holloway.
Fletcher, George Rory John, L.S.A., East Dulwich.
Green, Henry Lee, M.D. Penn., Muscatine.
Guthrie, Leonard George, L.S.A., Phillimore-gardens.
Lang, Walter Scott, M.B. Edin., Edinburgh.
Paterson, William Whiteside, M.B. Glasg., Ayr, N.B.
Rake, Herbert Vaughan, L.S.A., Fordinbridge.
Riley, Roland John, L.R.C.P. Ed., Bedworth.
Thomas, William Thelwall, M.B. Edin., Liverpool.
Tyndall, Francis, L.S.A., Liverpool.
Webster, George Alexander, Hobart, Tasmania.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations recently held the following gentlemen were admitted Licentiates of the College:—

John A. Coen, Shuldham H. Dunlop, Martin Fitzgerald, Edward Garraway, Lawrence Geoghegan, Edward W. Hamilton, John C. Jellett, Peter McSwiney, Andrew E. Murphy, William J. Shee, Patrick Stephenson, Charles P. Tennant, Archibald McLeod, and Guy C. L'Estrange.

COLLEGE OF PHYSICIANS IN IRELAND.—At the April examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Edward George Browne, Clarence Edwin Lloyd Gilbert, Alexander Gordon, Charles William Graham, Henry Charles Groves, Andrew Harris, John Keany, Richard Robert Leeper, Frederic Mercer, Michael Joseph Ryan, Charles William Thompson, Joseph Alexander Tooner, Charles Henry Wild.

MIDWIFERY.—Edward George Browne, George Foott, Alexander Gordon, Andrew Harris, John Keany, Frederic Mercer, Michael Joseph Ryan, Joseph Alexander Tooner.

The undermentioned has been admitted a Member:—

James Charles Hardy Peacocke.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 15th inst.:—

Baumgartner, Henry Spelman, Newcastle-on-Tyne.
Coleclough, John Arthur, Holloway.
Evans, Charles Silvester, Harbury-terrace, Fenterman-road.
Fletcher, Geo. Rory J., "Croome," Kelmore-grove, East Dulwich.
Guthrie, Leonard George, Phillimore-gardens.
Kempster, Felix Charles, Oak House, Bridge-road, Battersea.
Thomas, Thomas Nash, Lecka Sobra, Pembrokeshire.

A rich merchant, M. Chludow, has left more than £100,000 and a house to found a children's hospital in Moscow.

ON the 17th inst. a demonstration of friendly and trade societies was held in the East-end of London in aid of the funds of the proposed Cottage Hospital for West Ham.

SIR P. DUN'S HOSPITAL, DUBLIN.—The governors have received £326 towards the Fever Hospital Building Fund, and will commence its construction as soon as a sufficient amount has been obtained.

BELFAST MAIN DRAINAGE SCHEME.—This Bill will be considered in Committee after the Easter holidays, and it is believed that its progress so far as local bodies are concerned will not be much interfered with.

A LABOURER was fined 20*s.* and costs at Shrewsbury last week for having travelled in a public conveyance whilst suffering from small-pox. The defence was based on ignorance of the nature of the malady that had seized the defendant. A similar case was decided at Hartlepool on the 13th, in which a young man was fined 6*s.* 6*d.* and costs for exposing himself in public whilst labouring under small-pox.

GUY'S HOSPITAL.—The Michael Harris prize in Anatomy has been divided between Mr. A. Parkin, of Hightown, Yorkshire, and Mr. R. D. Mothersole, of Colchester. The Beaney Prize of 30 guineas in Pathology has been awarded to Mr. J. W. Washbourn, of Gloucester.

GRIMSBY HOSPITAL.—At the quarterly meeting of the Hospital Committee held recently, the treasurer reported the receipt of a bequest of £1000 free of legacy duty, and £40 as one year's interest thereon, under the will of Mr. John Vere, shipwright.

LIVERPOOL HOSPITAL SATURDAY FUND.—An address to the industrial population of the city has been issued by the Working Men's Committee of the Liverpool Hospital Saturday Fund, in the hope of stimulating interest in the important annual collections in aid of the local medical charities. The collection will this year be made on May 29th.

PRACTICAL ANATOMY AT OXFORD UNIVERSITY.—The guardians of the Reading Union, having been applied to by Dr. Burdon-Sanderson, Professor of Physiology at Oxford, that the bodies of unclaimed paupers might be handed over, under the provisions of the Anatomy Act, to the School of Anatomy at the University, as they have a dearth of subjects for the dissecting-room, have just declined the request by seven votes to six.

REFORMS IN THE DRIFFIELD UNION.—The guardians of the Driffield Union are about to introduce some sweeping reforms, upon the recommendation of the medical officer, who has made a special point of the prison-like restraint in which the paupers live, and in his report contrasted their gloomy lives with those passed by the inmates of Scotch workhouses. The children are to be provided with toys, have greater freedom, and an improved dietary, and there is to be throughout the establishment a less free use of lock and key.

THE POLLUTION OF THE RIVER LEA.—At the meeting of the Select Committee on this subject on the 16th inst., Mr. G. A. Eachus, engineer to the Edmonton Local Board of Health, was examined, and suggested as an immediate and temporary remedy for the existing pollution a thorough flushing of the river. The main want of the entire district was, in his opinion, an improvement of the subsoil drainage and the widening and deepening of the new cut. Mr. Croft, surveyor to the Tottenham Board of Health, also gave evidence, and the committee subsequently adjourned to the 14th prox.

THE PARKES MUSEUM.—An extraordinary general meeting of the members of this Museum was held on Friday, April 16th, Professor Berkeley Hill in the chair. The meeting was called to consider the desirability of amalgamating with the Sanitary Institute, and it was unanimously resolved, on the motion of Dr. G. V. Poore, seconded by Mr. Mark H. Judge, "That it is desirable that the objects for which the Parkes Museum and Sanitary Institute respectively were established should, if practicable, be prosecuted in the future by one corporate body." Further resolutions for bringing about this amalgamation and for applying for a Royal Charter were considered, but it was decided to adjourn the meeting in order that amendments to the resolutions might be sent to the whole of the members.

PRESENTATIONS.—On the 15th inst., Dr. Alfred Carpenter was presented by the Liberals of the Reigate division of the county of Surrey with a silver salver and dessert service in token of their appreciation of the services he rendered and the zeal and ability he displayed in contesting the division at the last election.—A very handsome illuminated address framed in oak has been presented by the Ancient Order of Foresters, Court 2385, to Mr. J. S. Hooker on his leaving Midhurst. The officers of the Midhurst Union Workhouse have presented to Mr. Hooker, on the same occasion, a handsome marble timepiece as a mark of esteem and respect.—A handsome silver inkstand has been presented to Mr. Jeffreys, of Chesterfield, in recognition of his generous efforts on behalf of Dr. Bradley. It bears the following inscription:—"Presented to Mr. Jeffreys by a number of the subscribers to the Bradley Fund, to record their high sense of his generous, self-denying, and successful exertions on behalf of Dr. Bradley. March, 1886." The list of contributors contains the names of many leading members of the profession in London and the provinces.

Digitized by Google

THE Russian Red Cross Society had treated more than 500 sick and wounded in their hospital in Sofia when the staff returned to Moscow.

DR. DYAKOVSKI, who has a medico-mechanical institution in St. Petersburg, has arranged to give the students of the Military Medical Academy free instruction in medical gymnastics and massage.

MEDICAL SCHOLARSHIPS.—At St. Thomas's Hospital Medical School the William Tite Scholarship of £30 has been awarded to Mr. Arthur Francis Stabb; the Peacock Scholarship of 40 guineas per annum for two years to Mr. Francis C. Abbott; the third year winter college prize of £20 to Mr. C. H. Eccles; the third year winter college prize of £15 to Mr. Edmund Hobhouse; the third year winter college prize of £10, in addition to second tenure of the Musgrave Scholarship of 40 guineas, to Mr. F. Fawssett; the second year winter college prize of £20 to Mr. Thomas P. Cowen; the second year winter college prize of £10 to Mr. H. G. Turney; the first year winter college prize of £20 to Mr. A. C. Lancester; and the first year winter college prize of £10 to Mr. C. R. Box. At the London Hospital Medical College the Hospital Scholarship, of the value of £20, for proficiency and zeal in clinical medicine, has been awarded to Mr. G. C. W. Wright; and that of £20 for proficiency and zeal in clinical surgery to Mr. H. G. Lys.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The quarterly court of the directors of this Society was held on April 14th; the President, Sir James Paget, in the chair. Two new members were elected; the deaths of five were reported, including that of Mr. Cooper Forster, a vice-president. Applications for relief were read from sixty widows, nine orphans, and three orphans on the Copeland Fund, and a sum of £1280 was recommended for distribution at the next court. One fresh application was read, and a grant at the rate of £30 per annum was made. The deaths of five widows were announced. A legacy of £50 from the executors of Miss Syne had been received. It was resolved to recommend for election, at the annual general meeting, as a vice-president, Sir William Bowman, F.R.S., in the place of Mr. Cooper Forster (deceased); and Messrs. T. H. Smith, Merriman, Vasey, Hutchinson, and Drs. Potter and Godson as directors in the place of the six senior, who retire. The annual general meeting was fixed to take place at 5 P.M. on May 9th.

BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.—The fifth annual meeting of the governors of this hospital was held on April 15th, in the board-room, Newhall-street. The Mayor (Alderman Martineau) presided. The report stated that during the past year 1142 patients were treated for skin disease, 810 for lock disease, and 45 for miscellaneous diseases. The attendances were 13,616. After referring with regret to the death of Dr. Russell and Dr. Heslop, the report showed that the necessity for larger premises became yearly more urgent, and that after careful consideration it was decided to build a new hospital with provision for beds and baths, as originally intended. For this purpose a piece of land had been secured in the centre of the town. The cost of erecting and suitably furnishing the building was estimated at £5000; towards this sum legacies, donations, and the surplus of ordinary income amounted to £1200, so that a further sum of £3800 was needed.

THE LABOURERS ACT (IRELAND).—At an inquiry held by an inspector of the Local Government Board for Ireland last week at Oldcastle, county Meath, as to the schemes promoted by the guardians for the erection of upwards of 200 labourers' cottages, evidence was given showing the urgent necessity for their construction. The medical officers of the union stated that many of the existing labourers' houses were built of bog sods or of old timber, that the roofs were of very little use in keeping out the rain, that some of the houses had no windows whatever, and that others were in danger of falling on the occupants. In one instance, in which there were ten in family, the entire dwelling only measured four yards by two, and an ordinary person could not stand upright in it. One labourer, on being asked to describe his house, said he might as well live under a riddle, as he could count the stars through the roof! There is no doubt that if the Act is properly carried out it must prove of considerable benefit to a large number of the labouring classes.

THE PANAMA CANAL.—M. de Lesseps, who has recently returned from Panama, read a paper at a late meeting of the French Academy of Sciences giving an account of the progress of the great canal works. The sanitary condition of the workmen he described as "relatively good," contrary to the unfavourable prophecies which were freely uttered at the outset. In a hospital with 500 beds, M. de Lesseps found only 300 occupied.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

LEACH, ALFRED, L.R.C.S., L.S.A.Lond., has been appointed Medical Adviser to the St. Gabriel's (Warwick-square) Maternity, vice Dr. J. H. Lavies, resigned.

ROKETT, A. W. CHALMERS, M.A., M.B.Cantab., has been appointed Medical Officer of Health for the Urban Sanitary Authority, Burnham, Somerset, vice D. A. Fraser, M.R.C.S., resigned.

TURNER, NATHANIEL H., L.R.C.P.Lond., M.R.C.S., &c., has been appointed Junior Resident Medical Officer to the Royal Free Hospital, vice H. W. Dodd, resigned.

WALKER, JANE H., L.K.Q.C.P.I., and L.M., has been appointed Resident Medical Officer to the Wirral Hospital and Dispensary for Sick Children, Birkenhead.

WHITFORD, WILLIAM, M.D., M.Ch.Q.U.I., has been appointed Medical Officer for the Fifth and Sixth District of the Parish of Liverpool.

Births, Marriages, and Deaths.

BIRTHS.

BEAUMONT.—On the 16th inst., at Gipsy-hill, Upper Norwood, S.E., the wife of Edgar Beaumont, L.R.C.P.Lond., M.R.C.S. (prematurely), of a daughter.

BUTCHER.—On the 15th inst., as Clydesdale Villa, Windsor, the wife of W. Deane Butcher, M.R.C.S., of a daughter (stillborn).

CROWTHER.—On the 8th inst., at Southampton-row, Russell-square, the wife of William Harding Crowther, L.F.P.S.Glas., L.S.A.Lond., of a son.

DUKE.—On the 14th inst., at The Glen, Lewisham, S.E., the wife of J. C. Duke, M.R.C.S., of a son.

EDWARDS.—On the 16th ult., at Tui Yüen, China, the wife of Henry Edwards, M.B., of a son.

GRAY.—On the 15th inst., at Albert-park, Melbourne, the wife of Charles E. Gray, B.A., M.D., M.Ch., Trinity College, Dublin (late Royal Navy), of a daughter.

MURRAY.—On the 14th inst., at Meadowside, Putney, the wife of G. Stanley Murray, M.D., of a daughter.

PEARCE.—On the 14th inst., at Lennox Villa, Hurstpierpoint, the wife of Henry Pearce, Surgeon, of a son.

RUSHWORTH.—On the 19th inst., at Langdale, Goldhurst-terrace, South Hampstead, the wife of Frank Rushworth, M.B., of a daughter.

SHADWELL.—On the 16th inst., at Lynhurst, Walthamstow, Essex, the wife of St. Clair B. Shadwell, M.R.C.S., L.R.C.P., of a daughter.

SMITH.—On the 15th inst., at Richmond-road, Barnsbury, N., the wife of Gilbert T. Smith, M.R.C.S., of a son.

MARRIAGES.

COLQUHOUN—MACMILLAN.—On the 2nd ult., at St. Matthew's, Dunedin, New Zealand, by the Rev. F. G. M. Powell, Daniel Colquhoun, M.D.Lond., M.R.C.P.Lond. (late Senior Assistant Physician, Charing-cross Hospital), of High-street, Dunedin, to Christian Campbell Macmillan, daughter of Thomas Macmillan, of 31, Ridge-road, Hornsey.

JACKSON—NICOL.—On the 14th inst., at St. Luke's, Westbourne-park, John William Jackson, M.R.C.S., of West-green, Tottenham, to Jane Ann (Jennie), fourth surviving daughter of F. A. M. Nicol, of Leamington-road-villas, Westbourne-park, W.

RAW—LEVIN.—On the 10th inst., at St. Mary's, Stoke Newington, William Edmund St. Michael Raw, L.R.C.P., M.R.C.S., L.S.A.Lond., of Rutland House, Oakfield-road, Penge, youngest son of the late Joseph Raw, to Edith Julia, eldest daughter of Edward Henry Levin, of Amhurst-road, Stoke Newington.

STEAVENSON—TRAVERS.—On the 21st inst., at St. Marylebone Parish Church, William Edward Steavenson, M.D., Downing College, Cambridge, son of the late Rev. Joseph Steavenson, of Shantock Hall, Bovingdon, Herts, to Dorothea Lloyd, daughter of the late Benjamin Travers, F.R.C.S., of Dover-street, Piccadilly.

DEATHS.

FOSBROKE.—On the 12th inst., at Bidford, George Haynes Fosbroke, M.R.C.S., L.S.A.Lond., in his 75th year.

ORWIN.—On the 16th inst., at Palace Chambers, Westminster (after a brief illness), Surgeon-Major Thomas William Orwin, A.M.D., eldest son of the late James Orwin, M.D., aged 47.

PENNINGTON.—On the 11th inst., at his residence, Devonshire-road, Prince's-park, Liverpool, Thos. Pennington, M.R.C.S., L.S.A.Lond., in his 79th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

UNIVERSITY OF CAMBRIDGE.

A CORRESPONDENT writes:—"For the sake of those who are going to Cambridge next October, it may be worth while to point out that a college is not necessarily a desirable one for a medical student because there are already many other medical students there. Those colleges which have the greatest number of medical students offer no more advantages to them than do other colleges which have few. I should advise those intending to go up to get advice from some resident member of the University who is well up in all the arrangements of the University for medical students; for in this respect the college tutors are very often lamentably deficient, having had little or no experience of such matters. All the colleges are open to medical students. This does not seem to be generally known. Even King's College, which for centuries has been closed to all except Eton men, is now, and for a long time has been, open to all comers, and, thanks to healthy reformation, offers no small advantages to medical and natural science students."

Peter is referred to the Students' Number of THE LANCET, published Sept. 12th last.

Mr. Cresswell.—The usual fee for a *qualitative* analysis is two guineas.

ACTION OF MUSCLE.

To the Editor of THE LANCET.

SIR,—In the report of a meeting of the Obstetrical Society of London on April 7th, published in your issue of April 17th, Dr. Horrocks is quoted as saying that "physiologists have formulated a law that whenever a muscle contracts, its opponent relaxes. This law is applicable to all muscle, voluntary or involuntary." In the same issue, Dr. Seymour Sharkey is reported (page 729) as saying, in his Gulstonian lectures, "Let me here refer to a class of spasmodic affections which appear to have the same explanation as tendon reflexes. Whether explicable as a reflex or purely local phenomenon, contraction of muscles occurs when they are put on the stretch by their antagonists; and this has the effect of controlling and steadying movements which might otherwise be jerky and uncertain." These two quotations appear to be contradictory. Is it not that sphincter muscles only are inhibited or actively dilate during contraction of their opponents, but that opposed muscles acting on joints contract together, though to an unequal degree?

I am, Sir, yours truly,

Ipswich, April 19th, 1886. JAS. NORMAN VOGAN.

ARTIFICIAL COLOURING MATTERS IN WINE.

DR. C. BLAREZ sends to the Bordeaux Medical and Surgical Society, in support of his candidature, a paper embodying the results of various observations he has made on the subject of the noxious effects produced by drinking liquids coloured with certain colouring matters derived from coal. Many of the observations were made on persons who, being medical or pharmaceutical students, were excellent subjects for the purpose. A number of experiments were also made by artificially carrying on the process of digestion with and without the addition of the colouring matters in question. The conclusions arrived at were that sulpho-fuchsine, which seems to be used for the coloration of wine, though it can hardly be looked upon as a poison, is nevertheless capable of setting up a good deal of gastric disturbance, especially if taken habitually by persons whose digestive powers are not very strong, the symptoms produced being generally colic and diarrhœa. The author found that this substance, as well as "Bordeaux red", and safranine, distinctly retarded the peptonisation of muscular fibrine.

House-Surgeon and Subscriber.—The question is a delicate one. We see no reason why a house-surgeon should not in certain cases receive fees for services rendered, provided that it is no part of his agreement with the authorities of a public charity to devote his time entirely to their interest. When, however, the services are given in the hospital, clearly the institution, and not he, is the proper recipient of the fees. The only case, in our opinion, where a house-surgeon should take a fee is when he is called upon to give evidence at an inquest on a body brought in dead. Many hospital surgeons—honorary—refuse to give certificates of incapacity or injury where any litigation is involved.

Messrs. Sampson Low and Co.—The subject scarcely comes within our province.

SOUTH CALIFORNIA AS A HEALTH RESORT IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—In your admirable leader of March 13th, which is now before me, you omit any mention of Southern California as a health resort for phthisis. If you had a practical acquaintance with the foot hills of the Sierra Madre range, you would, I think, class them amongst the finest climates of the world. Physicians in the eastern States of America send dozens of phthisical patients here every autumn; and I should like to point out a few of the advantages of this district to my professional brethren. The air is very dry, which, I believe, is generally considered a great desideratum, and we have no fogs, though they are found in the valley. The elevation is about 1800 feet above sea level. The winter climate is very equable—the days are pleasant and generally sunny, and the nights cool and refreshing. In summer there are, perhaps, half a dozen nights when one can dispense with a blanket, but as a rule one or two are required. Out-door exercise is possible every day, except during rain; but the ground absorbs moisture so readily that in half an hour after a fall of rain patients can walk out without getting muddy. The sea is about thirty-five miles distant, and the breeze from that quarter tempers the heat of summer. There are not many days (perhaps four or five) when the thermometer ranges over 90° F., and the heat is not felt so much as in England at 75° F. I came here about eighteen months ago, after two attacks of hæmoptysis, with a bad history of phthisis. I lost my mother, two brothers, and a sister from that disease. I first went to Los Angeles city; but after a residence of three months there, I found I was not so well, my left lung showing signs of giving way. Upon the recommendation of one of the first physicians in the city, I came out to Sierra Madre, and have done well ever since. I have no cough, and sometimes drive thirty miles a day seeing patients. This settlement comprises about fifty families, and about forty of them include a member who came here for "lung trouble." If patients come here in an early stage of the malady, they are almost certain to be cured. But even in more advanced cases the lives of patients may be prolonged years, instead of weeks. Space will not allow me to enter into details of cases; but, if desirable, I can, on some future occasion, give notes of a dozen cases which have come under my notice. We have pure air, pure water, fine scenery, good and cheap food, with strawberries, green peas, &c., every month in the year, and roses and geraniums in blossom all the winter. We are only sixteen to eighteen days by steamer and Pullman car from London. I shall be glad to answer any queries. I am, Sir, yours truly,

F. C. GRESHAM, M.D., M.R.C.S.

Bromley Knoll, Sierra Madre, Los Angeles County, South California, March 31st, 1886.

A FURTHER CURIOUS COINCIDENCE.

To the Editor of THE LANCET.

SIR,—There is an extraordinary sequel to "A Curious Coincidence," which you published last week. On April 15th—yet another week later—I obtained through a city music-seller two numbers of a musical cabinet, and both were defective. One contained a transposition of sixteen pages, and the other something wholly different from the table of contents printed on the cover. What does such a run of ill-luck in purchasing books portend? Will some modern representative of the genus astrologer or other occult science kindly inform me?—I am, Sir, yours truly,

April 16th, 1886. C. L.

THE CONSUMPTION OF TOBACCO.

THE Board of Trade returns for the quarter ending March disclose the fact that the consumption of tobacco in the United Kingdom has declined by 340,277 pounds weight, as compared with the corresponding period of last year. For several years up to the present time there has been a gradual increase in the consumption, notwithstanding the commercial depression which has prevailed, more or less, for the past eight years.

L.R.C.P.—There is no one book which contains the whole history of vaccination and statistics. But much information will be found in Seaton's Handbook of Vaccination, and very full statistics in the Reports of the Medical Officer of the Local Government Board for the years 1881 and 1884; also in the report of the German Vaccination Commission. This is now out of print, but a digest will shortly appear in the next volume of the Transactions of the Epidemiological Society (Shaw and Sons).

Mr. McGregor (Atlanta).—The paper referred to has not been received.

CHLOROFORM *v.* ETHER.

To the Editor of THE LANCET.

SIR,—The evidence in the Bartlett case has been of great interest to the public, lay and professional. Our knowledge of the action of such a universally employed drug as chloroform would seem from this case to be very limited, and the tendency of the evidence given must be to make the public more than ever prejudiced against that valuable anæsthetic. That ether ever will supersede chloroform in the general favour of practitioners may be doubted. It has every chance given it, for its praises are everywhere sounded to the detriment of chloroform; but I think if the collective opinion of the profession could be taken, chloroform would poll two votes to ether's one. Patients have often said to me, "Is not chloroform very dangerous? I thought everyone gave ether now-a-days." And that is exactly what a layman would conclude from reading this latest and most sensational trial. I was for a considerable time house-surgeon to a northern hospital where accidents were frequent, and I had a very fair experience in the use of anæsthetics. I can remember distinctly administering the A.C.E. mixture, which, after extended trial, I believe to be the safest and best, to a muscular young man, a collier, who came in with a fractured thigh. He was placed in the separate ward used for first admissions, and on proceeding to set the fracture I found him asleep, very soundly, evidently worn out with pain. I remarked to the nurse at the time that it would be a good case to test the possibility of giving an anæsthetic during sleep, and I applied the A.C.E. mixture as usual on a cone of spongio-piline. I withdrew it as he sniffed and seemed likely to wake, and then applied it again, as he relapsed into slumber, and although he turned over and was restless, he awoke not, and I put up the fracture in the usual way. I well remember his astonishment when, on recovering consciousness, he found his leg bandaged; he regarded the whole transaction as something "uncanny." The A.C.E. is decidedly more irritating to the air-passages than plain chloroform, and the inference would be that the latter might have been very easily given to the sleeper. I have on two or three occasions chloroformed children during sleep; but so, I suppose, has everyone who has had much use of anæsthetics. The A.C.E. seems very safe and handy in obstetric practice for several reasons.

I am, Sir, yours faithfully,

JOHN G. MARSHALL, M.B.Cantab.,
Hon. Surgeon, Mosley Convalescent Home.

St. Margaret's Bay, Dover, April 17th, 1886.

THE REARING OF HAND-FED INFANTS.

DR. NEWHAM of Winslow has had printed on a handbill the letter from Dr. Walker of Spondon, near Derby, which appeared in our columns on Aug. 23rd of last year, on Dr. Frankland's method of preparing artificial human milk. Any effort to spread amongst mothers correct information on the subject of infant feeding is commendable.

Dr. B. Ryley.—We sympathise with our correspondent in the annoyance to which he has been put, but do not see that any good would result from publishing his letter.

Mr. J. Harper's paper is marked for early insertion.

"HEALING BY FIRST INTENTION AFTER OPERATION FOR FISTULA."

To the Editor of THE LANCET.

SIR,—I have read the interesting annotation on the above subject in your last issue (p. 756), describing Dr. Ruidnovski's successful case. A few weeks ago an adult patient presented himself amongst the out-patients at the Western Hospital for Fistula, and he stated that he had recently been discharged from one of the large London hospitals (mentioning its name), where he had had a fistula "sewn up," but that he was just as bad now as before the operation. I examined him, and found that he was suffering from a complete anal fistula, with a long sinus, and as the suture marks were visible I concluded his tale was true. Knowing the surgeon by name who had performed the operation, I sent the patient back to him. I am, Sir, yours faithfully,

Bennett-street, St. James's, April 19th, 1886. SAMUEL BENTON.

TYPE WRITING.

Our attention has lately been directed to the advantages gained by medical men having lectures or papers to be read at meetings copied in type writing. Such copies are read with much ease and comfort, the clearness of the print saving much time and sparing to a considerable extent the eyesight. An office for such work in which ladies are employed has been established, and the quality of the work and the low price at which a single copy can be produced will doubtless induce considerable patronage to a venture which aims at providing what in these days is scarce enough—a suitable employment for ladies whose circumstances compel them to earn, wholly or in part, their living.

Kentigern.—1. Journal of Cutaneous and Venereal Diseases (New York: W. Wood); Annales de Dermatologie et de Syphiliographie (Paris: Masson).—2. Dr. D. Powell's work, of which a third edition has just been published.

THE USE OF THE ELECTRO-MAGNET IN SURGERY.

To the Editor of THE LANCET.

SIR,—Magneto-electricity has achieved such good results in the extraction of metallic substances from the eye, that I would beg to inquire if it has proved as successful elsewhere? I have to record a case of failure, where, in scrubbing a floor, a needle ran into the palm of the hand over the head of the third metacarpal bone, before last Christmas, and broke off. There were no indications of its exact whereabouts, and no suppuration; but some movements of the fingers being interfered with, Dr. H. R. South, R.N., very kindly took the patient on board H.M.S. *Vernon*, and having cut down over the site, applied an enormously powerful electro-magnet without withdrawing the needle, nor did the patient feel any prick or dragging, &c. However, it was there; for on April 3rd, some "soreness" having occurred on the back of the hand opposite the place of entry, I cut down (under Esmarch), and after some probing, felt, and removed, a portion of needle seven-eighths of an inch in length, black and smooth. I am, Sir, yours truly,

April 20th, 1886. W. M. H.

B.—The interest or good-will of a retiring practitioner is generally allowed to extend to his appointments as well as his private patients. He cannot, of course, promise the transfer of either, but it is good for what it is worth. How much it is worth depends on circumstances. Our correspondent is quite at liberty to try for a public appointment so vacated.

Student should apply to the secretary of the college mentioned.

EDUCATION OF DEAF-MUTES.

To the Editor of THE LANCET.

SIR,—In your last issue you refer to the education of the blind in board schools, and, in doing so, express the hope that some day the instruction of deaf-mutes may be included within the widening range of the board school administration. You are evidently unaware that with many school boards this is already an accomplished fact. The School Board for London has classes for deaf-mutes in various parts of the metropolis under the able superintendence of the Rev. Wm. Stainer, whose staff is in part trained at the Fitzroy-square Training College for teachers of the deaf. School boards in the country have followed the example, and I continually receive applications for the supply of teachers for the opening of new classes.

I am, Sir, your obedient servant,

WILLIAM VAN PRAAGH.

The Association for the Oral Instruction of the Deaf and Dumb,
11, Fitzroy-square, W., April 19th, 1886.

X. Y. Z.—The paper by Dr. Austin Flint on the Elements of Prognosis in Bright's Disease was published in the "Journal of the American Medical Association" for January 9th of the present year.

TENDER FEET.

To the Editor of THE LANCET.

SIR,—Perhaps some of your readers would be good enough to suggest a treatment for tender feet. For the last twenty years since my childhood, I have been almost entirely prevented from taking outdoor exercise from the pain consequent on walking; and nothing I have tried has been of any benefit. The apparent cause is thickening of the epithelium on the sole of the foot. I am, Sir, yours truly,

April 20th, 1886. X.

"APOPLEXY WITH COMPLETE HEMIPLEGIA."

To the Editor of THE LANCET.

SIR,—In reference to my case of the above, I beg to say that I myself thought it might have been due to embolism; but there was no previous history to point to any cause of embolism, and the same bruit remained after the seizure. I regret I cannot tell Mr. Boys if the murmur exists at the present date. I am, Sir, yours truly,

Ashburton, Devon, April 13th, 1886. WILLIAM FRASER, M.B.

ERRATA.—In our report of the meeting of the Medical Society of London, p. 741, referring to Mr. Brudenell Carter's case of Mules's operation, we should have stated that an artificial vitreous body *was* employed.—In the first paragraph of the lettter of our Manchester correspondent last week, the proportion of morphia in the dose of medicine was erroneously stated to be "18¾ grains." It should have been 1¾ grains.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Croonian Lectures

ON

SOME POINTS IN THE PATHOLOGY OF RHEUMATISM, GOUT, AND DIABETES.

Delivered at the Royal College of Physicians of London, April, 1886.

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

LECTURE III.

(*Concluded from page 774.*)

HAVING indicated the way in which the symptoms of rheumatism and gout may be produced, let me now appeal to clinical experience, and show how far the results obtained from the practical treatment of these disorders supports the view I have here advanced as to their pathology. If uric acid is the poison, the treatment for both diseases resolves itself into this: to prevent the formation of this substance, and when formed to promote its elimination from the system. The kidneys will in time effect the latter if we satisfy the first condition, and we may do this by seizing upon or eliminating the glycocine from the system; for as this is an essential constituent of uric acid, by removing it we prevent the further formation of that body, and so remove the irritating substance by which the action of the central nervous system is perverted. In gout this may be effected in some measure by benzoic acid. When benzoic acid is swallowed or introduced into the alimentary canal of a mammal, whether herbivorous or omnivorous, it appears in the urine as hippuric acid $C_9H_9NO_3$. The urine of adult herbivorous mammals contains no uric acid, this substance being replaced by hippuric acid, which varies in quantity both according to the food of the animal and the amount of work or exercise it has taken. Hippuric acid is also found, though in much smaller quantity, under normal circumstances, in human urine. Now hippuric acid may be decomposed by boiling it with strong hydrochloric acid into benzoic acid and glycocine:[1]

$$\underset{\text{hippuric acid}}{CH_2\begin{cases}NH\,.\,C_7H_5O\\COOH\end{cases}} + H_2O = \underset{\text{benzoic acid}}{C_6H_5\,.\,COOH} + \underset{\text{glycocine}}{CH_2(NH_2)COOH}$$

This action may be reversed, and by heating benzoic acid and glycocine in a sealed tube to 160° C. hippuric acid is formed.[2] It may also be formed by injecting benzoic acid and glycocine or bile into the blood of a living animal.

According to Kühne and Hallwachs,[3] benzoic acid injected alone into the jugular vein is not converted into hippuric acid, but it is if injected into the portal vein. Meissner and Shepard,[4] however, state that after injecting benzoic acid into the jugular vein of a rabbit, at first benzoic acid alone appeared in the urine, then more and more hippuric acid, and lastly hippuric acid alone. These experimenters maintain that hippuric acid is formed in the kidneys alone; but benzoic acid appearing first alone in the urine in the above experiment would hardly bear out that view, and Salomons,[5] after introducing benzoic acid into the stomach of a nephrotomised rabbit, obtained a decided amount of hippuric acid from the muscles, liver, and blood. Again, when benzoic acid is injected into the portal vein, of some animals at least, it appears as hippuric acid in the hepatic vein.[6] Hippuric acid also appears in the urine when benzoic acid is swallowed or introduced into the alimentary canal. Here it meets with the glycocine in the bile, and as they pass into the liver these are conjugated with elimination of water forming hippuric acid:

$$\underset{\text{benzoic acid}}{C_6H_4\begin{cases}H\\COOH\end{cases}} + \underset{\text{glycocine}}{CH_2\begin{cases}NH_2\\COOH\end{cases}} = \underset{\text{hippuric acid}}{C_6H_4\begin{cases}H\\CO\,.\,NH-CH_2-COOH\end{cases}} + H_2O.$$

The molecule CO . NH when the substance forms part of the tissue being transformed[7] into CNOH, and then living hippuric acid would be represented by the formula

$$C_6H_4\begin{cases}H\\CNOH\end{cases}\\CH_2\begin{cases}\\COOH\end{cases}$$

having a constitution of the same character as that of the molecules of living albumen. But benzoic acid, after passing through the liver, may be transformed in the tissues in two ways—into hippuric acid, either by being conjugated there with glycocine, or combining with the antecedent of glycocine.

In my previous lecture I endeavoured to show that this antecedent of glycocine is methene cyanalcohol $CH_2\begin{cases}OH\\CN\end{cases}$ which, acted upon by acids, would form glycollic acid, but if first treated with ammonia it forms a cyanamide, and then hydrated with acids or alkalies, forms glycocine.

When this substance and benzoic acid therefore are brought together in the tissues we should have

$$\underset{\text{methene cyanalcohol}}{CH_2\begin{cases}OH\\CN\end{cases}} + \underset{\text{benzoic acid}}{C_6H_4\begin{cases}H\\COOH\end{cases}} + 2H_2O$$

$$= \underset{\text{glycollic acid}}{CH_2\begin{cases}OH\\COOH\end{cases}} + \underset{\text{ammonium benzoate}}{C_6H_4\begin{cases}H\\COO\,.\,NH_4\end{cases}}$$

the latter of which when dehydrated being converted into benzonitrile,[8] this becomes

$$= \underset{\text{glycollic acid}}{CH_2\begin{cases}OH\\COOH\end{cases}} + \underset{\text{benzonitrile}}{C_6H_4\begin{cases}H\\CN\end{cases}} + 2H_2O$$

$$= \underset{\text{hippuric acid}}{CH_2\begin{cases}C_6H_4\begin{cases}H\\CNOH\end{cases}\\COOH\end{cases}} + 2H_2O$$

the formula which I have just shown to be that for living hippuric acid.

It is in this way that benzoic acid acts. It seizes upon the glycocine or its antecedent and so prevents the formation of uric acid; it passes out in the urine as hippuric acid, and gouty patients undoubtedly derive benefit from its use. Dr. Golding Bird prescribed it, in conjunction with phosphate and carbonate of soda with cinnamon-water, as a vehicle in gout. Dr. Garrod says: "I can confidently affirm that I have already obtained great advantage in the treatment of these diseases (gout and gravel) from the employment of the benzoates."[10] Doubt has been expressed whether the benzoates do diminish the uric acid excretion or not. Cook[11] states that in a healthy individual the administration of benzoic acid does not stop the formation of the normal amount of uric acid, but masks its presence in the urine and interferes with the murexide test. The later experiments of Dr. Noel Paton,[12] however, clearly demonstrate "that benzoate of soda really does diminish the uric acid secre-

tion." In an abnormal state of things, when there is an excessive amount of glycocine passing unchanged into the blood, the benzoic acid seizes upon this and converts it into hippuric acid; and so, if glycocine be necessary for the formation of uric acid, the amount of the latter must be correspondingly lessened. The remedy, however, must be given in sufficiently large doses, doses large enough to absorb all the glycocine, and then it may not only prevent the further formation of uric acid, but, as Cook's experiments show, it may render the uric acid already existing in the blood more soluble and therefore more readily eliminated by the kidneys.

Salicylic acid, or oxybenzoic acid $C_6H_4\begin{cases}OH\\COOH\end{cases}$ is another remedy which acts like benzoic acid, and this also has been found by Dr. Noel Paton[13] to diminish the excretion of uric acid. When administered internally it passes off by the urine as salicyluric acid—that is, it combines in its passage through the system either with glycocine or its antecedent, for on treating salicyluric acid with fuming hydrochloric acid it is resolved into salicylic acid and glycocine:

$$C_6H_4\begin{cases}OH\\CO\,.\,NH-CH_2-COOH\end{cases}+H_2O=C_6H_4\begin{cases}HO\\COOH\end{cases}+CH_2\begin{cases}NH_2\\COOH\end{cases}$$

salicyluric acid — salicylic acid — glycocine

Consequently, in the system, by seizing either upon glycocine or its antecedent, salicylic acid takes away an essential constituent of uric acid, and so prevents the formation of this body. As the salicyluric acid passes into the living system, the CO . NH would be transformed into CNOH, and the above formula for salicyluric acid would become

$$C_6H_4\begin{cases}OH\\CNOH\end{cases}\qquad CH_2\begin{cases}\\COOH\end{cases}$$

salicyluric acid

or, if salicylic acid combines with methene cyanalcohol the antecedent of glycocine in the tissues, it would then undergo similar changes to those I have described for benzoic acid—viz.:

$$C_6H_4\begin{cases}OH\\COOH\end{cases}+CH_2\begin{cases}OH\\CN\end{cases}=\qquad C_6H_4\begin{cases}OH\\CNOH\end{cases}\qquad CH_2\begin{cases}\\COOH\end{cases}$$

salicylic acid — methene cyanalcohol — salicyluric acid

In gout, uncomplicated with contracted kidney or albuminuria,[14] salicylic acid is often of service.[15] But it is in acute rheumatism that it shows its special power, acting truly, when properly administered, as a distinct specific. Here is a disorder which under different treatment may exist for weeks stationary, so to speak, in its intensity, the great heat, and nervous and vascular excitement, and pain, and swelling being exactly of the same amount to-day as they were weeks ago; a disorder which less than fifty years since was said to be "often such in itself and such in its appalling incidents as to need from time to time that medicine should put forth the full compass of all its powers. Every organ or system of organs which either directly or indirectly can receive the impression of remedies are from time to time called to bear all that they can possibly endure; and it is often only when the powers of medicine are pressed even to the verge of destroying life, that life is saved."[16] And now, with or without the administration of a purgative, as the occasion requires, the patient is placed fully under the influence of salicylic acid, and in from forty to sixty hours, not unfrequently in a shorter time, the pains in the joints have subsided, the limbs can be freely moved, and the bodily temperature has reached the normal condition. But more than this—and here the remedy shows its signal power,—in no case of rheumatism that has come under my care during the last six years, either in hospital or private practice, has there been, where the heart was previously sound, any cardiac complication, such as endocarditis or pericarditis, developed. If this can be maintained and ensured, we have indeed in our hands a most potent remedy. Cardiac complications constitute the chief danger of acute rheumatism, and the danger, if the disease is taken in hand soon enough, may with our new remedy be averted. But certain conditions must be observed to ensure success in the administration of the remedy. They are as follows:—1. The true salicylic acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialysed and purified. An impure acid will very quickly produce symptoms closely resembling delirium tremens. 2. Give the acid without any alkali or base. A very good form is to mix 100 grains with 15 grains of acacia powder and a little mucilage. Allow the mass to stand and harden, and then divide into thirty pills. 3. Place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance—i. e., buzzing in the ears or headache, or slight deafness; with the development of these symptoms the temperature and the pain in the joints will begin to decline. To an adult I generally administer three doses of 20 grains (six pills) at intervals of an hour, and if the head remains unaffected, a fourth dose at the end of another hour; and then repeat the 20 grains every four hours until the physiological effect of the remedy shows itself. In the majority of cases from 80 to 100 grains are enough. In severe cases 140 to 150 grains may be required. Afterwards about 80 grains a day are sufficient, and as the temperature declines smaller quantities will develop their physiological effects, 60 or even 50 grains being then sufficient to produce cerebral disturbance. It would appear that as long as the rheumatic poison is circulating in the system, the physiological effect—that is, the effect it produces in the healthy organism—does not show itself; acting as an antidote, the greater the amount of poison the larger must be the dose of the remedy; but as soon as the formation of the *materies morbi* is stopped, then the excess of the remedy acts as it would in the healthy organism and its peculiar physiological effects are developed. It is a very striking illustration of the difference between the therapeutic effect of a remedy and its physiological action. 4. Give the patient from 40 to 80 grains daily for ten days after all pain and pyrexia have passed away. 5. Let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. On the other hand, if the patient has meat and soup, you may look forward with fair probability to a relapse. 6. Take care to maintain a daily and complete action of the bowels. Calomel is the best purgative, from 2 to 5 grains at night, followed in the morning, if necessary, with a saline draught. This is the most important adjuvant to the action of salicylic acid, and I will presently explain to you why this is the case. 7. Let the patient be enveloped in a light blanket, and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient—not, as in former times, to sweat the poison out of him; and the cooler he is kept the sooner will the temperature be lowered. In fever increased heat increases the metabolism just as in a cold-blooded animal.[17]

These are the seven rules upon which I act. I have given the true salicylic acid where there have been both aortic and mitral mischief; and I have also given it in rheumatism complicated with pericarditis, and as yet I have seen no bad result from it. Of course in cases of pericarditis, accompanied with delirium, the use of the remedy requires caution; you cannot tell when the system is saturated with the remedy, and you must therefore trust to smaller doses and other means for controlling the disease. Further, if pericarditis or endocarditis, pneumonia, or pleurisy have been developed, the remedy is powerless over the mischief which is done; it will neutralise the poison producing the mischief so as to stop its extension, but the inflammatory exudations will undergo their usual changes unabbreviated in their course. We see the same thing in tonsillitis. Given early enough, salicylic acid will stop the mischief, but if exudation of lymph has taken place salicylic acid is powerless to cause its absorption.

There is another important point to be noticed here. In my first lecture I showed that from condensation of two molecules of $CH_2\begin{cases}OH\\CN\end{cases}$ lactic acid and carbonic acid could

[13] Loc. cit., p. 25.

[14] Paton's experiments show "that this drug has really an irritating action on the kidneys." Loc. cit., p. 25.

Digitized by Google

be formed.[18] By seizing therefore upon this antecedent of glycocine, salicylic acid lessens the formation both of uric acid and lactic acid.

During the administration of even large doses of salicylic acid in rheumatism, a certain amount of uric acid is still sometimes excreted by the kidneys. How is this to be explained?

As the molecular constituents of albumen fall asunder, the molecule $CH_2\begin{cases}CNOH\\CNOH\end{cases}$ may become detached, and as it passes from the living tissue the CNOH would be transformed into CO – NH, consequently the above molecule would be converted into hydantoin $CH_2\begin{cases}CO-NH\\|\\NH-CO\end{cases}$ which, having little affinity for salicylic acid, would pass on to the glands, and, conjugated with urea or biuret, pass out of the system as uric acid.

I have referred to the necessity of keeping up daily and sufficient action of the bowels. The benefits resulting generally, in rheumatism, from the so-called purgative plan of treatment have always been recognised by the older physicians as striking and satisfactory. By the judicious use of cholagogue purgatives we eliminate the bile from the intestines and so remove from the system a quantity of glycocine, which if re-absorbed would lead to the consequent formation of uric acid. Calomel is unquestionably of service here. Doubts may exist as to whether it promotes the flow of bile from the liver or not; but when the bile gets into the intestine calomel will cause its evacuation. "The conclusion seems inevitable that mercurial purgatives given to healthy persons cause the escape of large quantities of bile from the alimentary canal."[19] Referring to the three modes of treatment—by venesection, by opium, and by purgatives—which were in vogue at the time, Dr. P. M. Latham says with regard to the last: "As this plan of treatment works prosperously day after day in its immediate effects, so day after day it gives an earnest of the remedial impression it is exercising upon the whole disease. It abates the fever, it softens the pulse, it reduces the swelling, and it lessens the pain. In short, it subdues the vascular system like a bleeding, and pacifies the nervous system like an opiate; and often in the course of a week the acute rheumatism is gone. In three days there is often a signal mitigation of all the symptoms; and in a week I have often seen patients, who have been carried helpless into the hospital, and shrieking at the least jar or touch or movement of their limbs, risen from their beds, and walking about the ward quite free from pain.

"Of this plan, often so striking in its operation, and often so satisfactory in its results, I have some further remarks to make. It is called the purgative plan; yet its purpose is achieved by calomel and purgatives conjointly. The purgatives would not answer the end without the calomel—of that I am quite certain; neither would the calomel answer without the purgatives, unless it produced of itself ample evacuations from the bowels. It is probable, in short, that the remedial efficacy of the plan resides essentially in the calomel; in calomel, however, not as *mercury*, but as itself—*calomel*. If the specific effect of mercury—salivation—arise, it is not only beside our purpose and against our wish, but it begets a serious hindrance to the use of calomel in sufficient quantity for the end in view. Thus the whole plan is frustrated. Having begun one plan of treatment, we are obliged to take up with another. Time is lost, the case is perplexed, the disease is prolonged, and the patient perhaps injured. ..... Now, if in the treatment of acute rheumatism you were to choose one indication and abide by it, and were to trust one class of remedies and to it only, you would find more cases that admit of a readier cure by the method now described than by either of the former two. You would find the aggregate of morbid actions and sufferings, which constitute the disease, more surely reached and counteracted and more quickly abolished by medicines operating upon the abdominal viscera only than by those which influence either the bloodvessels only or the nerves only. You would find in calomel and purgatives a better remedy than in either venesection or in opium."[20]

In the earlier attacks of gout, too, I have often seen marked relief follow the administration of calomel and a saline cathartic. Where there is high arterial tension, as in the gouty paroxysm, this may be distinctly lowered by these remedies. They check the further formation of uric acid which is stimulating the vaso-motor centre and causing the increased arterial tension, by eliminating the bile from the intestines. In some persons calomel has a depressing effect, and when the kidneys are unsound is injurious in its action. Where calomel is inadmissible, a gentle laxative such as rhubarb is often of service. When the object is simply to unload the bowels in a debilitated subject, it is the best purgative. It is said to act chiefly by increasing the peristaltic action of the bowels throughout their entire extent, but especially that of the duodenum. According to Rutherford, it is a cholagogue. Sir Henry Halford recommended it as a prophylactic remedy against gout: a few grains of rhubarb with double the quantity of magnesia every day; or some light bitter infusion with tincture of rhubarb and about fifteen grains of bicarbonate of potash. The saline cathartics probably act only by causing serous evacuations, and in that way carry off from the blood some of the poison contained in it. They may also act beneficially, perhaps, by relieving a congested liver.

The diet is another important point to be attended to in the treatment both of gout and rheumatism. It should be simple and nutritious; jellies and food containing gelatine should be avoided, as this substance furnishes glycocine. Animal food will not itself produce uric acid in a healthy system, as is shown by its absence in the urine of the carnivora; but from all kinds of meat a certain amount of glycocine will be produced, and even if all the rest of the nitrogenous portion after being absorbed into the system were converted into urea, this would necessitate an increased elimination of urea, and consequently a greater tax on the powers of the kidneys. If these powers are weakened, there will be, with an increased call upon the organs, less power to act, and not only the urea, but, still more, the uric acid, would accumulate in the blood. The striking benefit and increased urinary secretion which result in some forms of albuminuria from a skim-milk diet—that is, the simplest of all diets—very well illustrate what I mean here. The presence of urea in the blood may, by its action on the nerve-centres, determine an increased blood-supply to the kidneys, and so, in a healthy state of things, an increased secretion; but if the secretory portion is damaged, or the nerve force controlling it defective, an increased flow of blood to the part, producing a congested condition of the organ, would not expedite, it would rather hinder, the work of the secretory portion. The simpler the diet then, the less tax there will be upon the kidneys, and the better they will do their work. Let the diet be chiefly farinaceous, with just sufficient nitrogenous food to satisfy the wants of the system—and in acute attacks let that be in the form of milk, diluted even if necessary.

The explanation which I have here offered of the symptoms of a gouty paroxysm helps us to understand the beneficial action of colchicum in this disorder. According to Dr. Lauder Brunton[21] this drug paralyses the sensory nerves, the motor nerves and muscles being unaffected. It seems to act best when the bowels are previously acted upon. If in gout, then, uric acid during the paroxysm is stimulating the sensory nerves and through them the more active portion of the vaso-motor centre, and we paralyse the sensory nerves with colchicum, the uric acid no longer produces its effect and the paroxysm ceases; but colchicum has no effect in preventing the formation of uric acid, and after the paroxysm we must endeavour to prevent its recurrence by putting a stop to the formation of the poison, which we may effect by eliminating the bile from the intestines by mercurial or other purgatives, by giving benzoic or salicylic acids and by suitable diet. In large doses colchicum will cause purging, but marked symptoms of collapse supervene, so that it is not safe to exhibit the remedy in this way.

It remains for me to say a very few words with regard to the pathology of diabetes, and to explain why I have classed it together with gout and rheumatism. If the function of the liver be interfered with, so that there is imperfect metabolism of glucose as it passes through the organ, this would be a satisfactory explanation of the origin of the disease, and we should expect in such cases that the urgency of some of the symptoms would be lessened by careful diet and abstention from saccharine and starchy food. But there are other cases in which the diet seems to have much less effect in controlling the symptoms; it is this form that I wish briefly to discuss.

I have endeavoured to show that in acute rheumatism, by the separation of the cyanalcohols $CH_2\begin{cases}OH\\CN\end{cases}$ and $C_2H_4\begin{cases}OH\\CN\end{cases}$ from the rest of the albumineous chain, we have glycocine and glycollic and lactic acids formed, the glycollic acid being oxidised into CO_2 and water, the lactic acid in some measure being oxidised into these products, and in some measure passing off by the skin. But suppose that whilst the vaso-motor fibres of the muscular nerve are paralysed and the vessels dilated, the molecules $CH_2\begin{cases}OH\\CN\end{cases}$ are detached and hydrated into glycollic acid, but only partially oxidised, the result would be that the glycollic acid would be transformed into carbonic acid, methyl aldehyde and water:

$$\underset{\text{glycollic acid}}{CH_2\begin{cases}OH\\COOH\end{cases}} + O = CO_2 + \underset{\text{methyl aldehyde}}{H\,.\,CHO} + H_2O$$

Condensation of six molecules of the aldehyde may then take place, as in plants, forming glucose:

$$\underset{\text{methyl aldehyde}}{6H\,.\,CHO} = \underset{\text{glucose}}{C_6H_{12}O_6}$$

By urari, as I have already stated, we can put a stop to muscular contraction, that is, to the oxidation of the muscular elements and to the formation of CO_2 when the muscular nerve is stimulated. If, then, the tissue be, so to speak, partially urarised, the aldehyde is not oxidised, but condenses into glucose. In urari-poisoning sugar appears in the urine, though "the exact way in which this form of diabetes is brought about has not yet been clearly made out."[22]

Let me carry you one step further in the comparison between rheumatic fever and diabetes. If in rheumatic fever the central part of the nervous system connected with the muscular nerves is so enfeebled that there is complete dilatation of the vessels in the muscular area, and a falling asunder not only of the molecules $CH_2\begin{cases}OH\\CN\end{cases}$, but also of the molecules $C_2H_4\begin{cases}OH\\CN\end{cases}$ and $C_3H_6\begin{cases}OH\\CN\end{cases}$ then by the hydration and oxidisation of these, hyperpyrexia would in some measure, as I have suggested, be developed. But if the complete oxidation of these molecules were interfered with, the $CH_2\begin{cases}OH\\CN\end{cases}$ would give rise in the manner above indicated to glucose. By hydration $C_2H_4\begin{cases}OH\\CN\end{cases}$ would be converted into lactic acid, which, if not completely oxidised into carbonic acid and water, would be first oxidised into carbonic acid and aldehyde:

$$\underset{\text{lactic acid}}{C_2H_4\begin{cases}OH\\COOH\end{cases}} + O = \underset{\text{aldehyde}}{CH_3\,.\,CHO} + CO_2 + H_2O$$

the aldehyde by condensation forming para-aldehyde, a remedy recently introduced as a hypnotic. Hence the drowsiness which shows itself in some stages of diabetes.

If the molecules fall still more completely asunder and the molecule $C_3H_6\begin{cases}OH\\CN\end{cases}$ become detached and hydrated into oxybutyric acid, but only partially oxidised, then from one form of this acid, acetone would be formed:

$$\underset{\text{oxyisobutyric acid}}{C_3H_6\begin{cases}OH\\COOH\end{cases}} + O = CO_2 + H_2O + \underset{\text{acetone}}{CO(CH_3)_2}$$

which appears in the urine towards the termination of the disease. So, then, in hyperpyrexia there is detachment of the molecules from the benzene nucleus, with their hydration and rapid oxidation; whereas in acetonæmia there are detachment and hydration, but imperfect oxidation of the molecules. That is to say (if this theory is correct, and such experiments were possible), by urarising an individual suffering from rheumatism with pyrexia the urine would become saccharine; if hyperpyrexia were present, by urari the disorder would be transformed into acetonæmia.

Now you will find that in some forms of diabetes salicylic acid is of the greatest service, whereas in others no good results from its use. Given in doses of from ten to twenty grains three times a day, I have frequently seen it produce marked improvement, and Dr. Holden, of Sudbury, has shown me notes of cases, about to be published, where rapid amelioration of the symptoms has resulted from its use.

The urine in these cases contains often, in addition to glucose, an excess of uric acid, and the patients suffer from neuralgic pains in the joints and limbs. It also not infrequently contains some substance which dissolves cuprous oxide, and so more or less interferes with the application of Fehling's test. What this is has not yet been determined. My friend, Mr. Pattison Muir, kindly examined some specimens, and made out that it is some substance which readily dissolves calcic phosphate. Possibly it may be glycollic or lactic acid. If further examination should prove this to be the case, it would go a long way to support my view of the origin of this form of diabetes.

I have thus endeavoured to indicate some of the changes in the nervous system, the blood, and the tissues which may take place in diabetes, rheumatism, and gout, and to enlarge upon the text furnished by a far-seeing pathologist,[23] when he wrote: "Disturbance in the nervous system in some form and part may be regarded as a factor in every case of gout. There are reasons enough for thinking that changes in the nervous centre determine the locality of each gouty process, while changes in the blood and tissues determine its method and effects; and that thus we may explain the symmetries of disease in gout—sometimes bilateral, sometimes antero-posterior,—and thus its metastases."

My task is done. It only remains for me to thank you, Mr. President and the Censors, for giving me an opportunity of placing my views before the College, and to the distinguished Fellows and Members who have listened to me. I have brought together a number of facts, and endeavoured to draw certain inferences from them. The inferences may be wrong, but the facts remain; and I trust that in this way, at least, I may have helped to a better understanding of these disorders.

ABSTRACTS OF THE

Lumleian Lectures

ON THE

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

By WILLIAM H. STONE, M.A., F.R.C.P.

LECTURE II.

HAVING briefly reviewed the first lecture, Dr. Stone proceeded to say that he had estimated the electrical resistance of the human corpse by inserting silver needles through the skin into the flesh, by which means the influence of the insulating, badly conducting skin was eliminated. The result showed that the estimations made on the living human body were correct, for the resistance was found to be slightly higher—at all events, it was not lowered. The chief topic of the second lecture was electrolysis as it occurred in the human body. All fluids acted as electrolytic agents, and so also bodies imbibed with fluid. The classical works of Dubois-Reymond and Count du Moncel on human electrolysis were noticed. The lecturer then exhibited an artificial electrical schema, in which the solutions and poles employed were the same as he had made use of in his determinations of the electrical phenomena of the human body. That polarisation takes place was very evident, and it appears, when physically studied, in the form of increased resistance. The work of Dr. Waller and Dr. de Watteville, published in the Philosophical Transactions of 1882, was also referred to.

As it is clear that electrolysis goes on during the passage of a current of electricity through the body, it is equally clear that there must be an accumulation of electromotive force in the body. The body is therefore a secondary battery which can be charged with electricity; at least, that

Digitized by Google

is one way of interpreting the facts of experiment. The body can be charged, and, having its charge, it can also discharge. This fact was demonstrated to the audience by means of the galvanometer. It was first tried on the artificial electrical schema, and then on a living man. An initial "throw" or deflection of the galvanometer was observed when the charged schema or man was brought into electrical communication with the galvanometer. The initial "throw" subsides rapidly at first, but a permanent deflection of the galvanometer remains for some time, showing of course that the body or schema was still discharging. As to this capacity of the body to become charged and to discharge itself, Dr. Stone used to consider that it was of the nature of a condensation of electricity by the body, but he has modified his earlier views owing to certain investigations of Prof. Hughes; so that he now believes, with the last-mentioned authority, that it is a matter of self-induction of the body. The initial "throw" of the galvanometer represents this induction, and the permanent deflection corresponds to the counter-electromotive force. The discharging current continues steadily and for a much longer time than was anticipated.

The results of some observations on certain cases were next given. In one case of sciatica where the leg was greatly wasted, and in which the resistance was somewhat high, the man was charged for thirty minutes with ten bichromate cells, the current passing from foot to foot. The initial "throw" was represented by 250 divisions of the scale. That this was really due in great part to the patient was proved by eliminating the possible influence of the lead contacts. The second case was one of diabetes. The patient was charged with a constant current of fourteen volts for half an hour, passing from the forehead to both feet, in a vessel of water. The resistance was found to be 600 ω, or after correction by Mance's method 543 ω. This case gave a polarisation current of no less than 137 ohm. The electro-therapeutical treatment of diabetes had been shown to be of transient value by M. Semmola. A third case, also of diabetes, was next related. The patient was very ill. His resistance was 1100 ω, or 1020 ω after correction by Mance's method. He gave a polarisation current equal to 145 ω, a very large counter-electromotive force, much larger than has ever been expected.

The resistance of the real man is somewhat less than that of the schema. As experiments already made by Dr. Stone with Mr. Lant Carpenter have shown, the resistance is increased by the polarisation resulting from the passage of the current. The charged body discharges very much after the fashion of a secondary battery. This information opens up a field of speculation in electricity as applied to the animal, and more especially to the human body. Even after but two volts have been used in the charging process, the body continues to discharge electrical force for several hours. Allowance being made for the swing of the galvanometer needle, it was shown that a current as feeble as two volts had the capacity to develop a counter-electromotive force which could be detected for some hours after the charging force had been removed. Two volts was a very feeble driving force, and only just sufficient to oppose and overcome the normal resistance, which might be appraised at about one volt. The electrostatic capacity of the body might be differentiated into a special capacity for condensing electricity and a capacity for electrolysis. But it is very doubtful whether a differentiation ought to be attempted; it was better to say that self-induction of the body took place. These researches have a very important bearing on physiological matters such as the phenomena of "electrotonos." Dr. Stone averred that he had always been sceptical as to the reality of electrotonos. The inconstant and variable results obtained by various authors working at this phenomenon were alluded to. Rosenthal admitted that the rise and fall of the electrotonic state sometimes went one way and sometimes another; and the paper by Dr. Waller and De Watteville, which quoted Fick, Eulenberg, Erb, Sanft, and others, showed what opposite conclusions had been come to. It had been suggested that the inconstant results were due to inconstancy of the nervous matter. But the lecturer humorously suggested that it was too bad to saddle the nervous matter with such inconstancy. The statements of Rosenthal were all consistent with conditions due to polarisation. He considered that too much stress had been laid on physiological points; no care had been made to ascertain whether the physical agent employed was always uniform. Anode and cathode were purely fictitious terms; the current might, for aught we knew, go in the opposite direction. We do know, however, something real about the two terminals and that related to electro-chemistry. The so-called positive terminal oxidises, whilst hydrogen is liberated, and bases are separated from the so-called negative pole. We know also that the passage of the current in the same way produces in the living human body a secondary battery of no inconsiderable power. Again, the phrases "cathelectrotonos" and "anelectrotonos" were unscientific; with weak currents the rise of cathelectrotonos was said to be near the anode; what was the meaning of that? It was probable that the phenomena of electrotonos ought really to be regarded as effects of electro-chemical decomposition in nervous tissue of a polarisation kind. Again, such inaccurate expressions as currents of medium strength were held up to deprecation; we ought to know what the intensity of the current was in ampères. If the electromotive force of the current is sufficiently strong to overpower the counter-electromotive force of the body, electrolysis will take place. But no means have been taken to measure this. Rosenthal admits that the effects are inconstant. There is also a possible error in the tetanising key of Dubois-Reymond, which did not cut off the current entirely from the long circuit. Here the law of inverse proportions also held good; most of the current goes through the short circuit, but some still traverses the long circuit, and this was another source of inconstant effects. If the induction coil be added to the constant current, the problem becomes infinitely more complicated and physically past accurate solution; if the induction coil alone be used, the problem is sufficiently complex. According to Waller and de Watteville,[1] the laws of diffusion are the same for each current; but Dr. Stone asserts that this is a distinctly false assumption. The induced current meets with but half to two-thirds the resistance of the constant, the exact proportion being 1141 ω to 575 ω. In believing that they had to deal with physiological signs alone, authors had fallen into error. As above shown, Dr. Stone maintains that the physical constants have not all been determined. Another point that has stood in the way of accuracy was the employment of over-sensitive galvanometers. Again, the entirely empirical indications of the galvanoscopic frog, no two of which have the same constants—nor can these be determined,—gave false results. So that whilst allowing that the phenomena, though admittedly inconstant, have been well and carefully observed, the lecturer was decidedly of opinion that much of the inconstant results—laboriously misunderstood and ingeniously misinterpreted—would prove to be due to purely physical conditions. The lecturer then demonstrated the telephone method of detecting and estimating electrical currents. It was a method of great delicacy, and had the inestimable advantage that it could be commanded, controlled, and measured. It might take the place of the galvanometer in Wheatstone's bridge, for the telephone could be silenced when the resistances in the two coils were equal.

A CASE OF SO-CALLED HYDROPHOBIA;

WITH REMARKS ON THE NATURE AND TREATMENT OF THIS DISORDER.

By CHARLES W. DULLES, M.D.,

FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA AND OF THE ACADEMY OF SURGERY, SURGEON TO THE OUT-PATIENT DEPARTMENTS OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA AND OF THE PRESBYTERIAN HOSPITAL IN PHILADELPHIA.

ABOUT two years ago I had just completed the preparation of a paper on the "Disorders mistaken for Hydrophobia,"[2] in which I had attempted to describe systematically the sources of error which I believed to lie at the foundation of a large number of diagnoses of hydrophobia, when I was suddenly summoned at midnight to the assistance of a colleague who had the care of what he thought to be a case of this disorder. The occasion was welcome, as affording me a new opportunity to study clinically this subject, which has so much engaged my attention; but it was also trying, since I felt that at this very time any error—although it might be due solely to my own incapacity—would seriously compro-

mise what I believed to be an important truth. With this thought to counsel prudence, I soon found myself in the presence of the patient, and in the midst of such a scene of horror and confusion as those can recall who have been so unfortunate as to witness a case of so-called hydrophobia. The essential features of the case may be described as follows: The patient was a little boy, about eight years old, of previous good health, who had been taken sick on the afternoon of the preceding day, March 16th, 1884. He first complained of a toothache, did not wish to eat, and had some pain in the stomach and in the throat. In a few hours he began to have nausea, and vomited. At first the vomited matter was "phlegm." He was said to have refused absolutely to swallow anything solid or fluid, although when I saw him there was no special prejudice against water; and, in fact, he was induced to take some from a spoon. He had also developed delirium, jumping up and running away from the couch upon which he was placed. He had fever and irregular convulsive movements, and was said to have "barked like a dog." Dr. Chase, having been called to see him, found that a tooth, which the boy said ached, was very loose, and pulled it out with his fingers. Led by the evidences of dysphagia mentioned, and noting the unwillingness to drink, he made inquiry and learned that the boy had been bitten by a dog more than twenty months before. The idea of hydrophobia presented itself to his mind, and he began a course of treatment to quiet the nervous system. This consisted in the administration of bromide of potassium, followed by suppositories of chloral hydrate, and later one-twelfth of a grain of morphia hypodermically, in spite of which the vomiting and the delirium continued. At this point he requested that I should see the case in consultation with him.

On my arrival, I found, in a small room containing a hot stove and crowded to suffocation, a well-nourished-looking small boy sitting on a lounge partly held by his father, tossing himself about, making inarticulate cries, constantly retching, and vomiting a glairy grumous fluid, in small quantity and with great effort. His penis was a little turgid, but not erect. His eyeballs were movable, but they moved slowly, and were directed upwards most of the time. His pupils were widely dilated, so that a mere line of the iris was visible. The corneæ were very dry. The conjunctivæ were congested, and, like the corneæ, were dry. The pulse was very rapid and tumultuous, the breathing catching. The legs, being constantly exposed, were cool, the body was warm, and the head was hot. The heat of the head was most marked at the temples. There was no excessive perspiration. There was great sensitiveness upon pressure on the forehead, which always excited resistance and convulsive movements. The ears were scarlet. The tongue was not especially dry. There was no spitting and no aerophobia whatever. The child was susceptible to the influence of soothing tones, and at intervals he seemed to know those about him, and to attempt to reply to questions. After making these observations we had the child removed to a well-aired room where we could be alone, and a new examination was made, every organ, so far as was possible, being passed in review. The conclusion I arrived at after this examination was that the membranes of the brain were inflamed, both on its convexity and at the base. There was now much jactitation, but the efforts at vomiting were less frequent. The boy had phantasies—stretching out his hands and talking in thick tones to comrades whom he fancied to be present. At times he seemed to be in terror, but at no time was it clear what shape the object which frightened him assumed. He struggled, but without any preternatural strength, against the little restraint which was occasionally required to keep him from getting out of bed. At times he appeared to be pretty calm, but he never was quite himself. Slight pressure on his forehead produced new paroxysms. All this time there was no aerophobia or dread of noise or light. The pupils were always dilated. We decided to give the child no more medicine, but applied cloths wrung out of hot water to his spine. These seemed to afford a little relief. After a while we determined to administer large injections of cool water, in order to produce a soothing effect and to wash away any irritant which might be in the lower bowel. The first injection consisted of over a quart of cool water, and it passed beyond the sigmoid flexure, as we ascertained by a physical examination, and was retained about fifteen minutes. Under its influence the patient was manifestly soothed, and his agitations ceased almost entirely. This injection passed away in instalments. After an interval of about half an hour another injection was given, but this was expelled almost immediately. With neither was there any discharge of fæces. (The necropsy showed the whole bowel to have been washed clean.) After this the patient seemed to be decidedly more comfortable, and we left him in the sole care of his father, who watched over him with great solicitude. His breathing had become quieter, and he had ceased to toss himself about as he had done, when, at 3 A.M., Dr. Chase and I left him, promising to return soon. We did return at 7.30 A.M., and found that the child, after a few hours of comparative peace, had expired quietly at 7 o'clock.

A necropsy was made three hours after death, at which Drs. A. F. Chase, W. E. Hughes, and myself were present. The body was still warm, the chest and throat most so, and the legs were cool. The eyes were partly closed and the pupils less dilated than when we last saw him. Rigor mortis very marked. Face and back cyanotic. On the free border of the upper lip, near its middle, was a small linear cicatrix, which was said to be the mark of a dog-bite received over twenty months before. On examining the head, all the vessels of the scalp were found gorged with blood. On removing the skull-cap, the bone was found to adhere very firmly to the dura mater in a number of places, chiefly along and near the superior longitudinal sinus. The most marked adherence was along the course of the left middle meningeal artery. This was bordered by thickening and roughening of the outer surface of the dura mater. The venous channels of the dura mater were full of dark blood. There were a large number of old adhesions between the dura mater and the arachnoid. These were very marked under the frontal and middle cerebral lobes, and most conspicuous and numerous between the medulla oblongata and the cerebellum. Some adhesions were also found under the cerebellum. The vessels of the surface of the brain were stuffed with blood. A quantity of blood and serum, estimated at three fluid ounces, was found at the base of the brain, in the cavity of the arachnoid. It was thought that about half of this came from the divided vessels. The puncta vasculosa were very well marked, and exuded dark blood. The ventricles did not contain any excess of fluid. The ependyma was injected. There were some delicate adhesions between the walls of the lateral ventricles, and between these and the choroid plexus. On cross section, the left optic nerve showed appearances of congestion, and even of extravasation. At the base of the brain there were many points of adhesion between the arachnoid and the dura mater and pia mater. On the floor of the fourth ventricle there was an appearance of marked congestion, and a few small extravasations the size of a pin's head. In the cerebellum nothing abnormal was found, except the evidence of inflammation of the membranes. There were no signs of recent lymph on the membranes. The lungs were engorged with blood, but perfectly crepitant, though there was some lobular collapse. There was no emphysema. The pericardium was healthy-looking, and contained a normal amount of clear serum. The heart was of normal size, healthy-looking, firmly contracted, and contained in the left ventricle a small quantity of dark clot, with a very little white clot in the pulmonary artery. There were a few small extravasations beneath the visceral layer of the pericardium. The abdominal viscera appeared to be perfectly healthy, except the liver, which had a slightly fatty appearance. The mesenteric glands were large, some the size of a large bean. None were cheesy. The bowels and stomach were almost entirely empty. (It will be remembered that the lower bowel had been washed out.) The gall-bladder was full of greenish-yellow bile. The urinary bladder was healthy, and firmly contracted upon about two drachms of clear urine.

Upon making further investigation as to the history of the child just before his illness, we learned that he had recently had a fall upon his vertex from a height of a few feet. We also found that the history of the bite was as follows:—One summer day (June 20th, 1882) the child was sitting on a door-step eating a piece of bread-and-butter, when a neighbour's dog ran up and snapped at it, in doing which he caught and tore the boy's upper lip slightly. The wound was not cauterised, and it healed without any trouble. The dog was caught and was shot by a policeman, at which the owner was very angry, insisting that the animal was perfectly healthy. No ill effect had followed the bite from the period of its infliction to the present time. In view of what we had learned of the history and from the symptoms

Digitized by Google

presented, I had made the diagnosis that this child was suffering from meningitis, and predicted that he would die in a few hours, and that if we could secure a necropsy we should find the evidences of inflammation both on the convexity and at the base of the brain. These predictions were absolutely verified, and I believed then, and I believe still, that the diagnosis was thereby fully sustained. Notwithstanding these facts, Dr. Chase considered the case to be one of hydrophobia. But was it? Let others judge for themselves. For my own part, as I have said, I firmly believe that it was a case of meningitis, and I felt at the time, and feel yet, that this experience justified, in the first crucial test to which they were subjected, the views which are expressed in the paper on the "Disorders mistaken for Hydrophobia," which was then so soon to be made public. Meningitis was one of the disorders about which I had not felt it necessary to argue much, because I thought that little argument would be needed. And yet, as I have said, the gentleman who called me to his assistance in this case insisted then, and still insists—against the evidence, as I believe, and in a line with what, without wishing to be invidious, I would designate as the popular impression—that it was a case of hydrophobia. I will admit that it has as many marks of genuineness as a vast number of the reported cases of hydrophobia. But here is just the trouble. It illustrates the greatest difficulty in getting at a scientific idea as to the nature of this disorder. The usual rule seems to be that, given a certain series of convulsive phenomena with unwillingness to swallow, which are not controlled by ordinary or even by extraordinary measures, and followed shortly by death, the case is one of hydrophobia. If it is followed by recovery it is said to be spurious hydrophobia. The fact that the patient was bitten by a mad dog is confirmatory of, but not indispensable to, the diagnosis. The madness of the dog, and even the fact of a bite or lick, may be assumed from the phenomena presented by the patient. This I believe to be the source of grave errors. If ever we are to have an accurate scientific understanding of what goes by the name of hydrophobia or rabies in men or in animals, we must first learn to define these terms better than they have ever yet been defined. I cannot repeat here what I have elsewhere considered in detail;[3] but I desire briefly to state that I have found that there are no essential differences in the clinical phenomena or issue of cases of so-called hydrophobia attributed to the most various causes: to the bites of a great variety of animals, rabid and healthy, including birds, fleas, and lice (Bollinger, Jolly); to the bites of human beings; to germs distributed in the earth and air (Doléris); to the kissing of a mad dog before it was hung (Bardsley); to drinking the milk of a rabid animal, to suckling (Roucher), and to coitus (Bollinger); to the handling of sabres used in killing rabid dogs (Virchow); and, finally, to a spontaneous origin, the most recent illustration of which was a patient who died under the care of Dr. Dujardin-Beaumetz, in Paris, in January of this very year. In one of the papers already mentioned I have described the occurrence of the symptoms of hydrophobia in a large number of disorders, and I here only refer to it for one of the most interesting and important phases of this literally vital question.

I cannot conclude without saying something in regard to the curability of hydrophobia. My studies have led me to the conviction that the prevailing despair as to the issue of this disorder is a sad mistake. Whatever hydrophobia may be, it cannot be said to be incurable. As genuine cases have recovered as have ever died. There is no better evidence for believing in the occurrence of hydrophobia than there is for believing it has been and can be cured. It is not consistent to hold to the one and to deny the other. To call cases that recover spurious is to beg the question. If there is a definition of hydrophobia which can be said to bear the stamp of authority, it fits a large number of cases which have recovered; and to assume that the disorder is always fatal is to select the worst way either to understand or to combat it. In fact, I think we shall have better notions in regard to the whole subject of hydrophobia, if we compare the disorder to convulsions, and use the word "hydrophobia" just as we do the word "convulsions," to describe a series of phenomena which may be due to various causes. In some cases these causes as yet elude detection; in others a careful search will lead to their discovery. A rational method of treating what is called hydrophobia will never, I believe, be established until we recognise the fact that it is not a single morbid entity, not a specific inoculable disease, but, like convulsions, a series of phenomena, the first step to the treatment of which must consist in remembering that it may be due to a great many different causes, and in endeavouring to find out what is the cause in each particular case. In many cases it will be possible to discover some disease of which the hydrophobic symptoms are merely epiphenomena. This done, the prognosis and the treatment must be made to conform to the diagnosis. When this becomes a custom, we shall less often have deaths from acute meningitis, or pericarditis, or tetanus, or mania-à-potu, or acute mania of any kind, unjustly charged to hydrophobia. Nor shall we then hear so regularly of the fruitless administration of overwhelming doses of morphia, chloral, belladonna, or curare, which are as great a confession of the impotence of medical art as are the violent measures of restraint which are so often employed, and but little less a confession of this impotence than is the act of smothering a patient to death, which *is said* to have been practised in this year of grace in the State of New York!

NOTES ON A CASE OF

CIRRHOSIS OF THE LIVER PRESENTING UNUSUAL POINTS OF INTEREST.

BY SURGEON-MAJOR F. P. STAPLES,
MEDICAL STAFF.

A SHORT while since I was asked by my friend Dr. Patron, of this city, to see in consultation with him H. R——, a young man sixteen years of age, suffering from ascites, and who had been ill with that symptom for about two months. With the exception of the abdominal superficial veins not being much enlarged, the clinical characters of the dropsy were those of liver cirrhosis, and this opinion was strangely supported by the family history of the patient. Twelve months previously an elder brother had died of that disease, and a necropsy had confirmed the diagnosis; about a year previously to that event a sister succumbed to the same malady, and in her case also the disease of the liver was verified by post-mortem examination. In the case under notice the onset of the disease was very insidious, and it was not marked in any way by pain or other symptom of acute disease. Its progress was characterised rather by a gradual failure of health, and the first tangible symptom observed by his friends was his increasing abdomen. In coming to a diagnosis, we found some slight increase of the splenic dulness, and, as the patient had recently resided in a somewhat marshy district, Dr. Patron suggested an examination of the blood, to the results of which it will perhaps be most convenient next to allude. Altogether three examinations were made—viz., one at the period of the case first referred to, one about six weeks afterwards, and a third about ten days before death, which occurred in about three months from the date of the consultation. In the first examination there was an enormous excess of the colourless corpuscles, and these, without exception, apparently were covered with processes or projections which gave them the appearance of the dried fruit of the black pepper. I did not observe the amœboid movements of these processes described by Mr. Wharton Jones, but my examination was purely a clinical one, and, had it been sufficiently prolonged and repeated, no doubt I should have done so. In addition to these large cells, which almost filled the field of the microscope, there were also a number of molecules or granules, but the normal red corpuscles of the blood were not to be distinguished. In the second examination the large cells were still visible, but they had almost lost the cell or globular shape. They were for the most part somewhat triangular in outline, the processes forming the angles being more or less blunted, and the sides deviating somewhat, generally outwards, from the straight line. In the third examination the large cells had entirely disappeared, and the field was entirely occupied by amorphous particles in a plasma having a distinctly yellow colour.

It will be convenient next to complete the clinical history

Digitized by Google

of the case. From the period mentioned its progress was very rapid, and in about two months it was necessary to perform paracentesis. The usual relief to the embarrassed organs of the thorax followed this operation, but the patient suffered considerably from abdominal pain for about a week afterwards. The fluid reaccumulated with great rapidity, and in six weeks or thereabouts there was again necessity to tap him, but the performance of the operation was not desired by his relatives, and did not, in fact, from his then condition, seem advisable. Soon afterwards he was seized with hæmatemesis and died within a few days, death being preceded by an unusually long comatose stage—about seventy-two hours.

The post-mortem examination extended only to the abdominal cavity, permission to make a limited dissection only having been received. The liver, which was moderately contracted, presented the appearance of an ideal specimen of the hobnail variety of cirrhosis. The surface tumours resembled unripe cherries in size and appearance, and on the surface of some of them tortuous bloodvessels were to be seen. On a deep section being made, the division of the organ into spherical lobules, corresponding in size to those visible externally, was well observed. The surface was free from adhesions or other evidence of a peripheral inflammation. Sections under the microscope corresponded in appearance with the illustrations (after Dreschfeld and Young) of this disease in the New Sydenham Society's Atlas of Pathology. The spleen was enlarged, but only to a moderate extent. There was no sclerosis of its tissue, but this was somewhat more soft and friable than normal.

Remarks.—The foregoing case would appear to offer for consideration the following points of special interest—namely: 1. The age of the patient. 2. The fact of his having been the third successive member of the same family who died in adolescence from the disease in question. 3. The abnormal condition of the blood. I am aware that there is nothing extraordinary in the age of the patient, but still it is decidedly exceptional. It may be considered, further, in connexion with the second point, which seems to me to be a unique experience, and more especially when it can be alleged with absolute certainty that in none of the three cases was there a suspicion of any of those agencies with which we are accustomed to associate cirrhosis of the liver. It is to be recorded, however, in regard to one of those agencies, that there was a history of long-continued alcoholic excess on the part of the father of the children. It is true that his death, which took place about five years ago, was not due to liver disease, but to cerebral apoplexy; there is, however, a fair presumption that in his case there were degenerative hepatic changes due to the cause under observation. Did he then transmit to his offspring a diathesis hereditarily determining cirrhotic atrophy of the liver? That seems a fair inference from the detailed medical histories of the children, but in relation to the broad question of pathology the question is a new one, to me at any rate; but if it be possible to answer it in the affirmative from the foregoing experience, it will serve to explain some of those anomalous cases of this disease in regard to which Frerichs has written the following pregnant sentence: "There are undoubtedly causes of cirrhosis with which as yet we are totally unacquainted." There is next to be considered the question of the condition of the blood, and under this heading it is perhaps necessary to allude to the diagnosis of the case. It may be said that the patient was the subject of two intercurrent diseases—viz., cirrhosis of the liver and splenic leucocythemia. Such an impression was entertained during the clinical progress of the case, but obviously it was not supported by the post-mortem examination, and the blood-cells already described, although resembling those of leucocythemia, were larger and much more numerous than are generally the leucocytes, even in advanced splenic disease. How, then, is the condition of the blood to be accounted for? It is not expedient perhaps, in a scientific sense, to offer any explanation from a single case; but it is hoped rather that by placing it on record the attention of pathologists may be directed to a subject which does not yet appear to have received adequate investigation.

Gibraltar.

MR. GEORGE FISHER, M.B., C.M. Edin., a well-known Scotch doctor, was found late on Sunday night lying dead on a sofa in his back shop at Millport, Island of Cumbrae. The cause of death is as yet unknown.

A CASE OF PUERPERAL CONVULSIONS, WITH COMPLICATIONS.

BY W. TYRRELL BROOKS, M.B. LOND.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD.

ON Dec. 29th I was asked to see a case in consultation with Mr. Ballard of this town. The previous history was as follows. Mrs. T——, a young nervous woman, who had been under treatment at intervals for some years for neuralgia and other nervous affections, was expecting to be confined with her second child. On Dec. 19th she was seized with occasional convulsions, accompanied by pain and numbness of the right arm and leg, together with a slight dragging of the right leg in walking. The convulsions increased in severity until Dec. 22nd, when Mr. Ballard was sent for, who, finding the os uteri dilated and labour commenced, delivered the patient of a living child by instruments. After delivery the convulsions continued, but gradually became less severe. One convulsion occurred, however, of a much longer duration than the rest, after which the right side of the body was found to have become weaker than the corresponding side, and in a short time to have become completely paralysed. The convulsions after this became less frequent, and, instead of being general, were now limited to the upper part of the body. The last convulsion occurred on the sixth day after delivery. Ever since her confinement the patient had lain in a state of apathy, without speaking or taking notice of her surroundings. She, however, took readily a considerable quantity of liquid food, though she swallowed with a little difficulty. At first she passed her urine and fæces normally, but on the sixth day after delivery she began to pass them under her.

When I saw her on Dec. 29th she was lying in a state of unconsciousness. When spoken to sharply she endeavoured to put her tongue out, but failed. She followed my movements round the bed with her eyes, but would not follow the movements of my hand when asked to do so. The right leg and arm were completely paralysed, but had not lost sensation. On pricking the right arm or leg with a pin, she uttered a cry of pain, but did not speak, and drew away the corresponding member of the opposite side. Sensation on the left side was unimpaired. She expressed considerable pain when her right leg or arm was suddenly moved. The neck was extended and stiff, and any attempt to flex the head on the chest was resisted, the act being attended with considerable pain to the patient. The pupils were equal and reacted to light. There was not any evidence of facial paralysis. The pulse was 120, tense and hard; the heart sounds normal; respiration 36, rapid and shallow. Over the whole of the upper lobe of the right lung there was bronchial breathing with fine expiratory crepitation. The lochia had continued for three or four days after confinement and then ceased. The tongue was coated and the teeth covered with sordes. The temperature was 101°.

When I saw her again on Dec. 31st there was considerable improvement in the general condition. She had spoken since my last visit, and appeared more sensible. The urine and fæces had been passed normally. The pulse was 120, but much softer; temperature 99·5°; respiration 36. Over the upper lobe of the right lung there was bronchial breathing with abundant crepitation. On Jan. 1st the improvement was still more marked. She answered questions slowly and hesitatingly, but her articulation was perfect. The breath sounds over the right pulmonary upper lobe were softer, and the crepitation still abundant. Respiration 30; pulse 120; temperature 99·5°. There was slight movement of the muscles of the upper part of the right arm and of the right leg. She complained of pain in the head, running down the back of the neck, and although the head could be flexed on the chest, it was accompanied by much pain, together with resistance of the cervical muscles.

On Jan. 4th the patient was practically convalescent. The respiratory sounds over the upper lobe of the right lung were almost vesicular, and the crepitation much diminished. The temperature was normal; pulse 108; respiration 30. There was increased power in the right upper arm and leg, and also some movement of the left lower arm. The patient, though kept scrupulously clean by the nurse, had

Digitized by Google

developed a bedsore. Since then the case has progressed favourably, and power has gradually returned to the paralysed side.

Remarks.—The case presents several points of interest. 1. The occurrence of puerperal convulsions, without the presence of albuminuria, in a neurotic patient, which continued for six days after delivery. 2. The supervention of right hemiplegia, which came on slowly after a very long convulsion, and in the course of a few days gradually disappeared. This was unaccompanied by facial paralysis, but was followed by the appearance of a bedsore. The gradual onset of and recovery from hemiplegia points, I think, to the occurrence of a small hæmorrhage in connexion with the internal capsule of the opposite side. 3. The presence of aphasia, which, although accompanied by right hemiplegia, I believe to have been functional. This was indicated by the aphasia having preceded the hemiplegia by two or three days, and also by the fact that the recovery of speech was sudden and complete. 4. The pneumonia, which was an extensive apical one, was of a low form, the highest temperature being 101°. In conclusion, I must thank Mr. Ballard for his kind assistance in the notes of the case, and for allowing me to see the patient during her convalescence.

EXCISION OF THE ENTIRE UTERUS FOR CANCER.

WITH NOTES OF A SUCCESSFUL OPERATION.

BY CHAS. E. JENNINGS, F.R.C.S. ENG., M.S.,
ASSISTANT-SURGEON TO THE CANCER AND NORTH-WEST LONDON HOSPITALS.

(Concluded from page 684.)

DR. WALLACE[1] relates four cases of uterine excision. The first two were vaginal hysterectomies for early cancer, and both patients recovered. The last two were for advanced cancer; one operation was performed by the vaginal, the other by the abdominal, method, and both patients died. With regard to partial excision of the uterus, Dr. Wallace[2] condemns the use of the écraseur, as liable to be followed by hæmorrhage, and as dangerous to the peritoneum and adjacent organs; he also cites a case where it was followed by fatal shock, and therefore he discards the écraseur for amputation. For partial excision Dr. Wallace recommends anterior and posterior semilunar vaginal incisions. The uterine arteries and lower parts of the broad ligaments are to be ligatured at a distance of half an inch from the ureters, and the broad ligaments divided between the ligatures and the uterus. The cervix is to be dragged upon forcibly, and severed as high up as possible with scissors. The stump and flaps are to be washed with iodised water, the vaginal flaps being closed with sutures passed through the stump. Where difficulty is experienced in ligaturing the uterine vessels, Sir Spencer Wells's pressure-forceps are to be applied and left *in situ* for thirty-six or forty-eight hours. This operation is only to be advised for very early cancer.

Dr. Carl Schroeder considers it always possible to extirpate the entire uterus, even if wholly diseased. The adjacent parts of the vagina can also be removed, but this author questions the advisability of operating in such cases on account of probable recurrence. Where cancer of the cervical mucous membrane and of the body of the uterus exists there is always necessity for total extirpation. For extirpation of the uterus, Schroeder advises a circular vaginal incision to be made near the cervix, and Douglas's space to be opened. The fundus uteri (retroflexed) is to be drawn down with a volsellum. The broad ligaments are to be ligatured either singly or in separate portions. Whilst removing the uterus a great deal of tissue is to be left between the ligatures and the organ, otherwise the ligatures will slip. The wound in the peritoneum is to be closed, stitching the pedicles into the angles of the wound. A T-shaped drainage-tube is to be inserted and the end wrapped round with salicylated cotton, which must be renewed as often as it is soaked. The stitches are to be removed in fourteen days. Above all, the uterus must be well drawn down during the operation, a proceeding very difficult where the vagina is narrow and the uterus very much enlarged. Schroeder had seven deaths out of twenty-three cases of vaginal extirpation of the uterus. In his hands supra-vaginal excision gave a death-rate of eight out of sixty-four cases, but recurrence generally took place in those who survived the operation.

Professor Olshausen,[3] in a letter to Sir Spencer Wells, recommended the employment of the elastic ligature for ligaturing the broad ligaments at a late stage of the operation. He employs a drainage-tube and iodoform gauze. The elastic ligatures are allowed to remain *in situ* for two or three weeks. Altogether Olshausen performed twenty-eight operations in two years and a half, three of which were supra-vaginal excisions; of these, all the patients recovered but one with a vesico-vaginal fistula. Out of the twenty-five cases of complete extirpation there were seven deaths—two on the day of operation, three of septicæmia on the second and third day, one of carbolic acid poisoning on the second day, and one of iodoform poisoning on the sixth day. Referring, however, to the last edition of Sir Spencer Wells's work,[4] it appears that up to the end of 1884 Olshausen had thirty-four cases of complete vaginal extirpation, with seven deaths. Since there were seven deaths in the first twenty-five cases, it follows that the last nine operations must have been performed without a death, a circumstance which supports the view that diminishing mortality will accompany increasing operative experience of uterine excision. "Among the cases where there had been no reappearance of disease, two years have elapsed in two cases, in one case two years and a half, and in two cases three years; but in a larger proportion there has been reappearance in between one and two years." Olshausen emphasises the fact that the special danger of the operation is injury to the ureters, which appear to have escaped by stripping them up, together with the loose cellular tissue which surrounds the supra-vaginal portion, by means of the fingers.

On the other hand, a case is recorded in which M. Jules Boeckel of Strasburg[5] *dissected out* the tissues between the uterus and bladder. A urinary fistula from injury to a ureter resulted, for which nephrectomy was performed, and the kidney removed was a healthy one. The patient recovered, left the hospital within six weeks of the first operation, and remained healthy, with the exception of polyuria, passing 1800 grammes of urine daily. She died in the seventh month, and a necropsy disclosed cancerous degeneration of the abdominal glands and parenchymatous inflammation of the remaining kidney.

A case is reported by Dr. Hennig (Leipsig)[6] where the patient had survived vaginal extirpation eight months at the time of communication. There was then no recurrence. The steps of this operation were—(1) anterior vaginal incision; (2) separation by the fingers of the anterior fold of the peritoneum; (3) anteversion of the uterus and enucleation of the organ; (4) removal of a cancerous nodule from the rectum. The wound in the rectum was closed by sutures. The entire length of the uterus was five inches and a half, and the cervix was entirely invaded by the neoplasm. The left ovary and Fallopian tube were removed, also half the right Fallopian tube. Enucleation, without opening the peritoneum, had been intended, but had not succeeded. Considerable peritonitis followed, but little hæmorrhage. A recto-vaginal fistula resulted, which was operated upon four weeks later. Four months afterwards a small recurrent nodule, which had arisen near the site of the fistula, was excised. There was no further recurrence.

Uterine excision by separation of the peritoneum was first proposed and successfully performed by Langenbeck. The woman survived the operation twenty-six years, but the uterus was not cancerous.

Dr. Gusserow,[7] one of the latest writers on uterine extirpation, has collected 253 cases (where the operation was performed by the vaginal method), with a mortality of 23·3 per cent., the list including operations from the time of Sauter (1822), Blundell (1828), and Récamier (1829).

Pfannestiel collects 154 operations up to 1882, with a mortality of 23 per cent.; but after 1882, thirty-six cases, with a mortality of only 8·3 per cent.

Gusserow advises the use of the curette and cautery as preliminary to making the vaginal and peritoneal incisions, so that when the uterus is retroflexed the chance of auto-

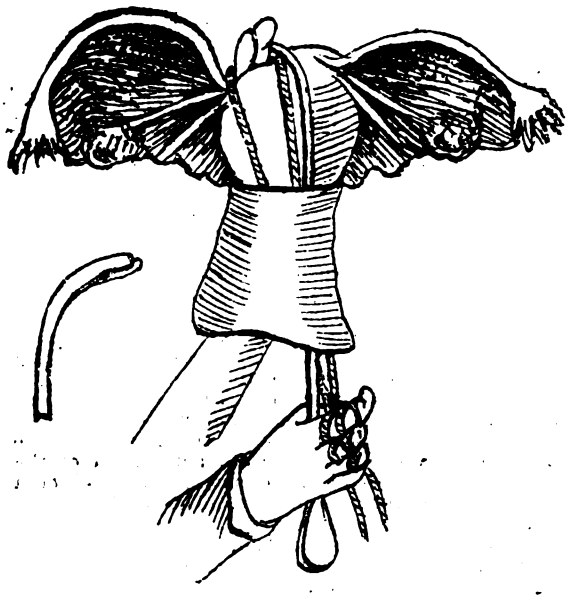
Digitized by Google

infection from the cancerous cervix will not exist. He considers flexion of the organ to be recommended as tending to check hæmorrhage by torsion.

These various modifications of the operation have been detailed because a study of the differences of procedure which they present may serve to afford the basis of a definite plan of operating, which may probably afford greater successes than those which have been devised in the past, and to further this object I have recently practised uterine extirpation upon the dead body, which enables me to submit the following points for consideration:—



1. There may be two semilunar vaginal incisions or one circular one. If the circular incision be chosen, the divided vaginal arteries can be readily secured by hæmostatic forceps. Before the incision is made the cervix should be well drawn down, thoroughly exposed, and the finger passed along the line of the proposed section, which should be principally made with blunt-pointed scissors, or a probe-pointed bistoury. The bladder should be supported with a staff throughout the operation.

2. The ureters are to be separated from the sides of the uterus with the fingers, and the peritoneum stripped upwards over the organ as high as possible, so that after its removal a funnel-shaped peritoneal flap will remain.

3. The uterine arteries should be secured prior to division.

4. The uterus should not be flexed, since such a course

FIG. 2.

involves greater difficulty in dealing with the broad ligaments, and might add to the risk of sepsis from the cancerous cervix.

5. The broad ligaments are to be secured as follows:—The peritoneal cavity having been freely opened in front of and behind the uterus, by tearing through the peritoneum with the finger-nails, the operator's left hand is to be introduced into Douglas's pouch, and the uterus pushed upwards towards the abdominal cavity in order to gain space. (Fig. 2). A loop of stout carbolised silk must be passed upwards in front of the uterus, by means of a staff shaped like a vesical sound, having a notch for the silk at the top of its beak. This loop can be caught by the tips of the left index and middle fingers at the summit of the uterus, and one end drawn downwards. By a similar manœuvre a second loop can be passed over the other broad ligament. (Fig. 3). Perforated shot are to be slipped upwards, each embracing a ligature, and clamped by pressure with a forceps such as that shown in the engraving, firm traction having been previously made upon the ligatures. The broad ligaments are secured close to the uterus.

6. Two courses are now open to the surgeon. By the first, a stout pair of Wells's pressure-forceps is applied to each broad ligament external to the silk ligatures, and the uterus then excised with scissors. In this case the silk ligatures will have served the purpose of temporarily compressing the broad ligaments and of depressing them into the jaws of the pressure-forceps. The forceps will be allowed to remain *in situ* for some hours in order to prevent hæmorrhage, and the operation completed as in the case of Mrs. R——. By the second course, double ligatures must be applied to the alæ vespertilionis, and these structures divided on either side between the double ligatures. The operation will then be completed by closing the peritoneal cavity, after the manner ordinarily adopted in abdominal operations.

It has been argued that the Fallopian tubes are part of the uterus, and therefore, unless they be removed also, excision of the uterus only, for cancer, is an imperfect procedure. Without discussing this debatable point, I will content myself by stating that after the excision of the uterus in the manner indicated, the operator can, if he please, draw down consecutively each appendage, apply a ligature, and remove it. But in so doing, care must be exercised to avoid including the ureters in the ligatures. Virginity naturally increases the difficulty of vaginal hysterectomy. In one of the operations I performed upon the dead body, the subject was a virgin, and it became necessary to incise the hymen in the median line with scissors. It was not necessary to divide the perineum, and the vagina was readily distended to a size large enough to admit the introduction of the entire hand. Deformity of the pelvis would seriously complicate the operation, and this or other

FIG. 3.

conditions which occasion diminution of the genital passage would guide the operator to choose the abdominal in preference to the vaginal operation, where hysterectomy is advisable.

The term "cancer" is employed in this communication in its most general sense—viz., as signifying a "malignant growth," and not merely as synonymous with "carcinoma." In support of my advocacy of early extirpation of the uterus for cancer—which, if performed after the manner laid down, with the greatest attention to Listerian principles, is not a particularly dangerous operation—it becomes necessary to express some opinion as to the nature of cancer, with the reasons for electing extirpation as a rule in preference to the more usual methods of treatment. The common idea on the cancer question (which is quite wrong) runs thus: "A hereditary and constitutional disease, distinguished by the presence of a tumour, which, if excised, generally recurs and destroys life. Why therefore operate for cancer which can at best retard the disease only, and is a course associated sometimes with a little, but sometimes with grave, danger? Let us pin our faith to harmless remedies and patent nostrums!" Speaking generally, a cancer tumour arises from

Digitized by Google

the combination of predisposing and exciting causes. In this, as in some other diseases, the degree of the one class of factors is inversely proportionate to the other. Locality has been recently urged as a cause of cancer, and statistics have been collected which argue forcibly in favour of this opinion. But as to whether certain atmospheric or telluric conditions predispose to or excite cancer, or what such conditions be, though they presumably exist, is quite unknown. Heredity is undoubtedly a most powerful predisponent to cancer. The influence of heredity has been questioned because a family history of cancer has not been forthcoming in a certain proportion of hospital cases; but Sir James Paget has shown that such a history is obtainable from private patients in twice as large a proportion. Add to this the circumstance that even among private patients a family history of cancer cannot always be traced and is very often intentionally suppressed, and the evidence in favour of heredity as a factor in the etiology of cancer becomes irrefragable. Mrs. R——'s case may be cited as a not uncommon instance of hereditary cancer, where the primary growth appeared in two sisters, probably in the same site. Mrs. R—— applied for treatment for cancer of the cervix uteri, with the history that a sister had died of "cancer of the bladder"—i.e., probably uterine cancer extending into the bladder. The *ipsissima verba* of a woman who I recollect consulted me last summer were: "Sir, two of my sisters have died of cancer of the womb, and now I have severe pain in the womb and an offensive discharge." In what respect syphilis influences cancer is questionable. That certain syphilitic lesions are frequently the precursors of cancer is admitted by all; but whether such lesions exert an influence which specifically initiates cancer or not is a matter of doubt. But this remains certain: many cancer-tumours arise from obviously exciting causes, which may be physiological, dependent upon the evolution or retrogression of the organs (e.g., the breast and uterus), or upon the natural decay of the tissues; or extraneous, such as smoker's lip cancer, or chimney-sweep's scrotal epithelioma (where the development of the growth is favoured by the scrotal corrugations which retain the soot). Fissures and ulcers, either simple or of specific origin, not uncommonly form the cradle and starting-point for epithelial growth.

Quite recently, the results of most valuable researches by Schuchardt have been published[3] in reference to his observations on the origin of cancer from chronic inflammations of the mucous membrane and skin:—1. He traces the steps between bucoal and lingual psoriasis and cancer of the cheek and tongue. A case fell under the observation of Schuchardt where psoriasis of the tongue had existed for many years in a dormant condition, but ultimately assumed the character of epithelioma. The tongue having been removed, the transition from the psoriasis to the epithelioma was demonstrated microscopically. The transition steps of epithelium from a chronic inflammation to a malignant growth have thus been proved; but why epithelium, at one time homotopic, may eventually become heterotopic, is the great question in the pathology of cancer which still remains to be solved. 2. Schuchardt also draws attention to the development of cancer of the penis from "psoriasis preputialis," by which he means a condition of phimosis with chronic inflammation of the prepuce. In confirmation of this, I may refer to the well-known origin of epithelioma from venereal warts which have been allowed to vegetate beneath the foreskin. 3. Instances are also adduced of "seborrhagische Hautcarcinome," or cancer arising from chronic inflammation of sebaceous glands.

The mode of origin of epithelioma of the cervix uteri is a hotbed of debate. By some it is contended that fissures, simple ulcers, and erosions of the cervix uteri give rise to no symptoms, produce no inconvenience, and are harmless; by others, that these conditions are a constant source of misery, are a cause of various reflex phenomena, and may serve as a suitable nidus for the development of cancer. With neither view do I entirely agree, but incline to the latter. A small fissure or ulcer of the rectum, a sore spot on the mucosa of the tongue or larynx, unquestionably give rise to a varying degree of distress; how, therefore, an erosion or ulcer on the cervix uteri can never produce symptoms either *per se* or in association with its usual concomitant conditions is difficult to understand. The initiation of cancer by external irritants has been dwelt upon at some length; its frequent origin from leucoma of the tongue, or from fissures and abrasions of the mucosa of that organ, has been proved, together with the logical prevention of cancer by the removal of such small foci by treatment, before they have assumed a chronic condition and become developed into a chronic inflammation. We are therefore constrained to think that fissures and simple ulcers of the cervix uteri, when permitted to run their course unchecked, frequently become the precursors of uterine cancer. At all events, however easy it may be to draw a hard and fast line upon paper of the differential diagnosis of simple chronic infiltration of the cervix and of the infiltration due to malignant disease, or to give the differential diagnosis of simple and cancerous ulceration, yet clinically no more difficult puzzle is presented to the practitioner than to form a correct opinion in many instances which fall under his observation. Such, in outline, is the evidence which supports the view that a cancer-tumour is, whilst small, a purely local affection, and immunity from recurrence usually attends early and *free* excisions of these tumours.

Unfortunately for themselves, patients affected with cancer are not usually presented to operators whilst the primary tumours are in their earliest stages, and the bulk of cases operated upon are in consequence those where the disease has progressed already too far to render the hope of cure by surgical treatment probable.

In conclusion, I venture to say that I have brought forward sufficient reasons to support the hope that vaginal extirpation of the uterus for cancer is an operation which will save life when performed sufficiently early in the course of the disease. In Mrs. R——'s case, Mr. Prowse has reported that the neoplasm has unfortunately recurred in the vaginal cicatrix in the fourth month after extirpation of the uterus. But the disease was far advanced at the time of operation, as shown by Fig. 1 (p. 683). My present feeling is wholly opposed to extirpation of the uterus for cancer of the fundus, chiefly on account of the difficulty which attends the diagnosis and precise determination of the extent of the disease in such cases. The death-rate following such operations will be high, and the chance of immunity from recurrence small. In cases of early cancer of the cervix the limitation of the neoplasm can be ascertained with tolerable certainty; the removal of the upper portion of the vagina together with the uterus would not add much to the risk of the operation, and would notably diminish the probability of recurrence. These are the kind of cases for which vaginal hysterectomy should be afforded a fair trial, and the results ought to be as good, at least, as those of recognised operations for cancer in other parts of the body. Mr. Foreman, writing from Sydney, states that he has excised the uterus for cancer per vaginam five times successfully, so far as the immediate results were considered. From this experience he adds: "I am convinced that, if we only get the cases before the neighbouring parts are infiltrated, the ultimate results would be far better than the removal of cancerous breasts. If a case be too fixed for removal, I leave it alone. In future I shall always extirpate where it is possible to do so."

SMALL-POX EPIDEMICS IN LONDON.

BY HENRY TOMKINS, M.D., B.Sc.,
MEDICAL OFFICER OF HEALTH, LEICESTER.

Now that London is comparatively free from small-pox and the fresh cases arising weekly can be counted on the fingers, and in view of the fact that the Metropolitan Asylums Board are about to take steps for the erection of another large hospital in preparation for what is apparently looked upon as inevitable — another epidemic of this disease,—the time appears opportune to bring forward all or any experience tending to throw light upon this matter. As the result of some years' experience of this subject, I would offer some observations relating thereto under the following two heads: first, the principles which should be followed in the providing of small-pox hospitals, both as regards the interests of the patients and those of the public; secondly, a more efficacious means of coping with the first outbreaks of the disease, in order to prevent its assuming such large proportions as have hitherto at regular intervals

Digitized by Google

been an opprobrium to the sanitary arrangements of the metropolis.

1. According to a leading article in THE LANCET of Feb. 20th, the Metropolitan Asylums Board have decided to build a new hospital at Gore Farm for 600 patients. At the late hospital at Darenth accommodation was provided for a much larger number than this. I would submit that the formation of such large establishments is a mistake, and for the following reasons. When the numbers begin to exceed 300, the difficulties of proper administration, supervision, and control are enormously increased, one important factor tending to this being that so large a proportion of the patients are convalescent and practically recovered, and are kept in hospital more as prisoners under restraint, waiting the time when they will be free from infection and fit to mix again with the community at large. Again, if this number be much exceeded, the area from which the cases are brought is much extended, and thus the patients have a further distance to be removed from their homes; and although experience has proved to me that cases of small-pox, if in a fit condition to be removed at all, will, in a proper ambulance, bear a journey of seven or eight miles without any apparent ill effects, still it is desirable on all grounds, financial and social, to limit the distance of removal, so far as this can be accomplished. Again, it has been shown that, on the score of economy, when a hospital exceeds 400 beds the total cost per bed begins to show a marked increase. The objection that has been raised as to the ill effects of too great aggregation on the patients themselves, in addition to that of the surrounding district, should also have some weight. The inmates in the acute stage may be estimated at 25 per cent., and it is these, if any, that suffer most from too close aggregation, and a total of 300 would limit these to some seventy or eighty, a number which it is desirable not much to exceed. It would therefore appear advisable on these grounds, if provision must be made for these large numbers, and this scourge is to be for ever at intervals widespread in London, to select, say, three or four sites—east, west, north, and south—situate beyond the thickly populated districts, where land is less costly, and where ten or twelve acres could be got at a distance not less than a quarter of a mile from any main thoroughfare or human dwelling-houses.

2. But a more important question, perhaps, than the provision of these large hospitals presents itself for consideration—viz., whether it is an inevitable necessity that these epidemics of small-pox are to periodically arise and hundreds of lives be lost thereby, in spite of the protection afforded by vaccination and our improved or supposed improved sanitary arrangements. Are all available means taken at the onset, and in each and every case, to prevent the spread of the infection? All who are acquainted with the details of these matters as in operation in London will agree in acknowledging that they are not. The population of London is fairly well vaccinated, and the greater number of those admitted into small-pox hospitals are found to have been vaccinated in infancy, so that the amount of protection afforded by one vaccination is pretty general; and yet what are the results? My attention has been forcibly directed to this point since undertaking the duties of medical officer of health to the borough of Leicester, so well known as the headquarters of the anti-vaccination movement, and where the vaccination laws are practically to a large extent in abeyance, as at the present time not much more than one-third of the children are vaccinated. This condition of things has now been going on for a few years, so that there must now be some thousands of children, forming a sensible proportion of the 140,000 inhabitants, which is about the present population of the town and district; and yet, with all this susceptible material and the frequent importation of small-pox into the town, and into the most densely populated parts of it, during the last eight or nine years the disease has never got a hold or spread amongst the people. To what is this due? There can be little doubt that it is due to the active vigilance of the health authorities. Compulsory notification of infectious diseases is in force, and it is not too much to say that within a few minutes from the receipt of information of a case the authorities are on its track, and the patient, *nolens volens*, is promptly removed to hospital. But, further, not only is the patient removed, but every effort, and indeed pressure of a most pronounced character, is brought to bear to effect the removal to quarantine wards of all those persons who have been in attendance on or in contact with the patient, there to undergo a fortnight's isolation and observation. In those instances where the friends &c. have not yielded to this pressure and could not be got into quarantine, a daily visit of observation has been made, so that the earliest symptom of any sickness amongst these should be known. By thus promptly removing every case, thoroughly disinfecting the infected premises, maintaining a strict watch on those exposed to infection, and preventing them from mixing with others at school or work, the disease has hitherto been kept from spreading.

I bring this forward as illustrating what vigilant action on the part of those concerned with the care of the public health has been able to accomplish, and that too amongst a crowded population a large number of which is unprotected, and not in any way to advocate the non-performance of vaccination, my views and experience of the latter being shown elsewhere.[1] In fact, one cannot with any degree of equanimity look forward to the future of this community; with a yearly increase in the unprotected portion of the population, it is to be feared that ultimately a Nemesis will overtake the town in the shape of a violent outbreak of variola. As a speaker at the Sanitary Congress held here in September last well said, Leicester may be likened to a town where the brick-built houses are gradually being replaced by wooden ones: for a time a fire occurring may by prompt action be extinguished without causing much damage; but by and by, when all the houses are of inflammable material, a fire will at last occur which will baffle all efforts to extinguish it.

What I wish to insist upon, however, is this: If such results can be obtained in a population of 140,000, why cannot the same be effected in a population of four millions? If these four millions are divided into twenty districts, each with a competent and sufficient staff, and its organisation properly adapted for the purpose to be accomplished, what is there to prevent similar results being obtained in each of these districts as here? To be of any use, action must be prompt, vigorous, and effective; half-hearted measures are useless in coping with this disease; it does not do to stand too much upon ceremony, and possibly at times the actual limit of legal powers may be exceeded if delay is to be avoided: violent diseases often require violent remedies. It is a truism to point out that the essentials for carrying out the above line of action are, first and foremost, the immediate notification of the occurrence of each case; secondly, an efficient staff to act on such information; thirdly, prompt action in removal, disinfection, revaccination, and watching all those who may possibly have been exposed to the infection.

ST. GEORGE'S HOSPITAL.

VOLVULUS OF ASCENDING COLON; DEATH; NECROPSY.

(Under the care of Dr. J. OWEN.)

THE cause of the obstruction in the following case is of considerable rarity, and for that reason the case is well worthy of record. Three varieties of incarceration, the consequence of rotatory movement, may take place,[2] and of these this case affords an example of the first—a simple twist of the bowel on its own axis. In previously recorded cases this simple twist has almost invariably been found in the ascending colon, and this case is no exception to the rule. For the following notes we are indebted to Drs. Delépine and Griffiths.

W. W——, aged twenty-nine, was admitted on August 17th, 1885. He was a slightly built man, who had had no illness

[1] The Protection afforded by Vaccination. Manchester: Cornish.
[2] Holmes's System of Surgery, vol. ii., p. 712.

Digitized by Google

except acute rheumatism in 1870. He had been in good health, with no loss of appetite, no abdominal pain, and perfect regularity of the bowels up to August 15th, when he was seized with sudden pain across the lower part of the abdomen, with constant vomiting, and that day there was no action of the bowels. Next day the vomiting was less constant, but the bowels remained constipated, and there were pains of a cramping character in the abdomen. There was no history of blow or strain or sudden movement, and no excess or error of diet.

When admitted on the 17th, his skin was cold; temperature 96·4°; pulse small and weak, 82; tongue clean. He vomited occasionally a dark yellow acid fluid, small in amount. His pupils were normal, but there was much restlessness and tremor of the hand. A short systolic murmur was audible over the apical area of the heart. Pulmonary sounds clear. Abdomen tense; umbilicus retracted; dulness (comparative) over right ileo-inguinal region and right flank; hyper-resonance above the umbilicus and over the left side. His pains were referred to the lower half of the abdomen, from one side to the other; palpation gave pain; no coils of intestine mapped out on the abdomen; reflexes over abdomen exaggerated; no vermicular action visible. Three full enemata failed to bring down more than a few scybala. He was given four ounces of brandy, and half a grain of extract of belladonna every two hours. He continued, however, to vomit, almost always ten minutes after drinking. He spoke cheerily of himself, was not collapsed, and about five hours after admission was heard to laugh at some incident; but within an hour and a quarter after that he was seized with muscular convulsions, became cyanosed, and died before aid could be summoned.

Necropsy, twenty-one hours after death.—There were a few adhesions of the pleura, and extensive old pericardial adhesions, with thickening of the mitral valve and slight thickening of the aortic valves, producing incompetency. The thoracic and abdominal organs were apparently healthy. The abdomen was distended, and there were a few ounces of dirty-looking turbid serum in the peritoneal cavity. On reflecting the omentum, the small intestine was found pushed upwards and to the right by a large blackish pouch. On following the small intestine from above, the distended pouch proved to be the distended and displaced cæcum, the ascending colon being twisted a short distance above the ileo-cæcal valve, the distended cæcum extending from the right iliac fossa to the left hypochondrium, forming a large elongated ovoid mass twelve inches in length by six inches wide, its peritoneal coat being torn in several places. The colour of the distended viscus varied from a purple-brown to an almost black colour. The stomach, and the whole of the small intestine contained a large amount of highly offensive flatus and fluid fæcal material. The lower two thirds of the ileum were much discoloured. Beyond the point of obstruction the colon was contracted and quite pale. The appendix vermiformis was still in the right iliac fossa, with the adjacent parts of the cæcum, both joined to the parietes by a mesentery which was much stretched, but otherwise presented no striking abnormality. The volvulus affected the lower part of the ascending colon, which was twisted, so that the anterior surface looked posteriorly—the parts of the right side looking upwards and to the right, the parts of the left side looking downwards and to the left. These relations apply only to the parts in the immediate vicinity of the volvulus. Thus the parts entering into the composition of the distended pouch were derived from the antero-external region of the cæcum and ascending colon and the postero-external wall of the caput cæcum. Before untwisting the volvulus water was passed through the descending colon, but could not be made to pass through the stricture, though on replacing the cæcum in its normal position both water and the contained gases passed freely. The cæcum and the ascending colon being laid open, the mucous membrane of the former was found to be discoloured, softened, and evidently partially destroyed at several points. At the point of obstruction, which was marked by a sudden transition from the dark colour of the distended intestine to the pale colour of the contracted ascending colon, there was a narrow line of deep arterial congestion, but with no great amount of swelling of the mucous membrane. There was no indication of previous constriction at that point, and on removing the constriction by untwisting the intestine the entire obstruction vanished.

The case was therefore one of volvulus of the ascending colon, and presented the peculiarity that no congenital malformation, general in such cases, could be found. The meso-cæcum was not even long enough to allow of any extensive displacement of the appendix vermiformis. It is evident, from the relations of the parts and from the position of the volvulus, that without a saccular distension of the antero-external part of the cæcum no volvulus could have existed, or at any rate have been persistent. It should be noted that there was a *secondary* twist due to displacement of the distended cæcum, which altered the position of parts; but, on untwisting it, the occlusion remained perfect as before.

RADCLIFFE INFIRMARY, OXFORD.

A CASE OF EXCISION OF THE THYROID GLAND; REMARKS.

(Under the care of Mr. HORATIO SYMONDS.)

WE are indebted for the following notes to Mr. George Rodman, M.B.

Rose C——, aged twenty, a housemaid, was admitted during the summer of 1885 suffering from an enlargement of the thyroid gland, which, in addition to being inconvenient on account of its size, gave her trouble in swallowing, and also produced some amount of dyspnœa.

When first seen, the patient, who was a healthy, robust girl, presented the usual signs of a thyroidal growth, involving both lobes, but more especially the right. There was no expansile pulsation of the tumour, nor other evidence of its being a case of Graves' disease. The difficulty of swallowing was not such as would interfere with nutrition, but the dyspnœa produced by exertion prevented the following of her occupation with any degree of comfort. There was no cardiac disease. Several attempts, four in number, were from time to time made, to promote a diminution in size of the mass; the process adopted being that of incising the growth, and then, by the application of the actual cautery to the incisions, promoting the formation of a scar, which, when it contracted, might diminish the blood-supply to the tumour. The girl left the hospital, and returned a month or so later with but little amelioration of her condition. She was then desirous of having a further operation performed.

On Oct. 27th, the A.C.E. mixture having been administered, Mr. Symonds proceeded, with Listerian precautions, to extirpate the growth, and to accomplish this made his incision over the most prominent portion on the right side, in the direction of the carotid vessels. The previous cauterisations had produced adherence of the skin to the subcutaneous structures and made the "shelling out" of the gland more difficult than it is usually found to be. Considerable hæmorrhage was encountered, which, however, was easily restrained by means of Spencer Wells' artery forceps and the application of catgut ligatures to the bleeding vessels. The actual cautery was used at one stage of the operation to check some venous oozing. A thick catgut ligature was passed round the junction of the isthmus and right lobe previous to the removal of the latter. At this stage of the operation it was decided, owing to the pulse giving evidence of collapse, to postpone the removal of the remaining lobe for a time. The skin wound was closed with silk sutures, a drainage-tube being inserted in the lower extremity of the incision. The portion removed was found to weigh twelve ounces, and a stained microscopical section showed it to consist of a simple hypertrophy of the gland, without any alteration in the relative amounts of gland and fibrous tisue.

The patient remained somewhat collapsed for twenty-four hours, but after this period gave no ground for alarm. It was only necessary to dress the wound a few times, and she made so rapid a recovery as to be able to take exercise in the grounds of the hospital three weeks after the operation.

On Nov. 20th Mr. Symonds removed the remaining lobe in a manner similar to that adopted on the previous occasion. The same difficulty, owing to adhesions, was found, and the extension of the growth behind the trachea rendered it necessary to employ great care in avoiding a wound of that tube. A portion of the isthmus was left over the front of windpipe, the left lobe having been separated from this by means of the cautery iron. No considerable hæmorrhage was met with, and there was a marked absence of collapse, as seen on the occasion of the removal of the right lobe. The weight of the left lobe was six ounces.

The subsequent history of the case is a somewhat interesting one, in that it caused some alarm to those attending her.

Digitized by Google

Shortly after the termination of the operation it was noticed that she was breathing stertorously, even though thoroughly roused from the anæsthetic. This stridor remained during almost the entire time she was in the hospital, and was especially audible when she was disturbed in any way—e.g., sitting up at the time of the dressings. Three days after the operation her temperature reached 102·4°, and with that she had a troublesome cough, with frothy expectoration and rapid stridulous breathing. The wound was healing well. Her temperature on Dec. 1st had reached its normal standard, but her voice was weak, and she suffered from peculiar paroxysms of an almost noiseless cough. The stridor was still present at intervals. She was up for the first time on Dec. 7th. On account of her continued weakness of voice, a laryngoscopic examination was made, but this was very unsatisfactory owing to her tonsils being large and preventing the insertion of the mirror between them. She continued in the same state till Dec. 26th, when her temperature suddenly rose, and continued high (between 103° and 104°) for several days. There were no other indications of fever. Subsequent investigations showed that she had in all probability caused the thermometer to rise either by its application to a hot bottle or by means of friction. Having been detected in this fraud, she left Oxford within a few days, during which interval her voice returned and she had no stridulous breathing. On Feb. 3rd, 1886, she presented herself at the hospital in good health, and was shown at the meeting of the British Medical Association there.

Remarks by Mr. SYMONDS.—Cases of bronchial and laryngeal spasm, due to irritation of a goitre, ending fatally, will justify the operation of removal of the thyroid gland in many instances of a simple enlargement of that body. It would be well, considering the attendant risk of the operation, which has probably been somewhat over-estimated, to try less active measures in the cystic variety of the disease. The same remark applies to the exophthalmic form when hæmorrhage might prove fatal. A previous cauterisation of the growth would seem to be contra-indicated, as being of not much use, and because of the complication that it leads to should an attempt at excision be made subsequently. The above case did not illustrate the usual comparative immunity from spasm during the day-time, a fact which was forcibly illustrated by the sudden death of a similar case, which happened to be in the ward at the same time, and which occurred from bronchial spasm in the middle of the night, the patient having shown some dyspnœa for several previous nights, though quite free during the earlier portion of the day. The line of incision was adopted as being less likely to injure the important structures met with in this region. Removal of the isthmus was avoided, with the idea that with that portion of the tumour remaining there would be less chance of the patient developing a myxœdematous condition. It remains to be seen whether such will be the case. I have known four other cases besides the one mentioned as dying of bronchial spasm in the ward, in which patients have died suddenly from asphyxia due to gradual compression of the trachea.

LIVERPOOL INFIRMARY FOR CHILDREN.

CARIES OF LAST DORSAL AND FIRST LUMBAR VERTEBRÆ, WITH PARTIAL PARAPLEGIA AND CONTRACTURE OF MUSCLES OF THIGHS, IN A GIRL AGED THIRTEEN; CURED, WITHOUT DEFORMITY, BY A SAYRE'S JACKET WORN CONTINUOUSLY FOR TEN MONTHS.

(Under the care of Mr. MARTIN OXLEY.)

ALICE P——, aged thirteen, was admitted on Feb. 2nd, 1885. It was stated that up to eight weeks previously to her admission she had been in good health. She first complained of pain in the small of her back and in her legs, and suffered most at night. She gradually became very thin, lost her power of walking, and her thighs were drawn up upon her abdomen.

On admission she was much emaciated, looked haggard and worn, and could not be moved without exciting spasmodic movements of the flexors of the legs, which were accompanied by great pain. She was kept in bed for two days, and then had a jacket of plaster applied while in the slings, after Sayre's plan. From the time she had the jacket on her pain ceased, and the tendon reflexes, which had been greatly exaggerated in the thighs, became almost normal. After eight days she could walk about in the ward, but soon got tired. She was sent home, and was not seen until December, 1885. She was then stout and well, and could run up and down the ward without the support of a jacket. Her mother stated that she had gradually got stronger and fatter, and was as well as she had ever been. Another jacket was put on, as the child wished to have further treatment, and as Mr. Oxley always continues the jacket for at least two years after the cure to ensure its permanency.

The girl was again seen last month (April). She is strong and well; can touch her toes with her fingers without bending the knees, except to a very slight degree. She has no pain in the back, nor does she show any deformity. Mr. Oxley has shown her to the members of the Medical Institution, and considers that her case is one of the most remarkable and interesting of the large number which he has treated.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Development of Mammary Functions by the Skin of Lying-in Women.—Paraplegia from Pott's Disease, and its Treatment by Actual Cautery.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., Vice-President, in the chair.

Dr. F. H. CHAMPNEYS contributed a paper on the Development of Mammary Functions by the Skin of Lying-in Women. After referring to numerical abnormalities of the breasts and nipples, the author proceeded to give thirty cases of the condition described in the title of this paper, occurring between October, 1882, and November, 1884, in the General Lying-in Hospital. The right side was affected in 14, the left in 1, both in 15. The lumps in the right side predominated both in frequency and size. The author then described the situation and characters of the bodies referred to, and their course of development; during lying-in this usually coincides generally with that of the breasts. The secretion was of three principal kinds: (*a*) Granular débris, like the secretion of sebaceous follicles; (*b*) colostrum; (*c*) milk. It was expressed from the situation of the sebaceous follicles, as marked by the situation of the hairs. The whole surface of the lump produced secretion; there was no centralisation. The cases were seen by numerous observers. Three typical cases were given at length, and instances of the following conditions were then described by way of contrast: Extension of mammæ into axillary folds; axillary mammæ with axillary nipples, pores, or ducts; supernumerary nipples without special gland substance (including one case having a typical "axillary lump" in the skin of the right axilla, and also three small "axillary lumps" on the right side, and three rudimentary nipples, two on the right side and one on the left). The cases of "axillary lumps" were believed to be now described for the first time. They seem to prove that in lying-in women the sebaceous follicles of the skin are capable of producing true mammary secretions. The transition from granular material, through colostrum, to true milk, is distinct and unmistakable. They confirm the opinion that the breast is a highly specialised aggregation of highly specialised sebaceous follicles. The least specialised form is that here described, where the skin is merely thickened, and the sebaceous glands may produce true mammary secretions. The next form is that where there is an aggregation of the ducts, which open by one or more external pores. The highest rudimentary form is where a nipple or more are superadded to the last variety. It is also well known that nipples may be developed independently. It is far from improbable that these "axillary lumps" may share the pathological affections of the breast, and even be the seat of abscess. Reference was made to some affections described by Verneuil as "hidrosadénite," and believed by him to be situated in the sweat-glands. A case of "axillary lump," painful during menstruation, was given. The paper concluded with a table of thirty cases of "axillary lumps," giving the side affected, dimensions, when first noticed, largest on which day, state when last seen, secretion, and remarks.—

Digitized by Google

Mr. G. D. POLLOCK believed that this was the first paper that had been contributed on the subject.—Mr. ALBAN DORAN said that Dr. Champneys' valuable researches supported the embryological as compared with the morphological view of the mode of origin of supernumerary nipples and glands. If these structures were really relics of organs in our ancestors, then they ought not to be found in the axilla, for in no animals did these glands occur in that situation. That Dr. Champneys' lumps were a specialised form of cutaneous sebaceous glands was highly probable.—Dr. CREIGHTON regarded Dr. Champneys' researches as having been productive of a considerable discovery. He believed, however, that the lumps or glands were not derived from sebaceous glands, but from another cutaneous structure that existed in the human axilla. He had incidentally described this glandular stratum in a paper read before the Society four or five years ago. Similar structures were met with in the skin of the dog. In the human axilla they had been described by Sappey, Kölliker, and Frey. These glands were coated by a remarkable layer of plain muscular fibres. They were composed of peculiar yellow granular cells, were of a larger size, and had a shorter neck than the ordinary convoluted sweat glands. In the Australian platypus Meckel had described them as glandula humoralis lymphatica. The remarkable muscular coating would enable a diagnosis to be made between them and sebaceous glands. This would afford a distinction when an opportunity arrived for an anatomical examination of a case of Dr. Champneys' lumps.—Dr. JOHN WILLIAMS said that during menstruation pain and fulness occurred frequently in the breast. It would be interesting to know, therefore, whether the axillary lumps of Dr. Champneys ever exhibited signs of their existence during menstruation. In one case which Dr. Williams had had the opportunity of watching, some swelling and pain in the axilla corresponding to the position of these lumps were detected.—Dr. BENNETT related a case of swelling in the axilla which was associated at the menstrual periods with sweating; the tumour was removed and found to be an oval flattened lipoma.—Dr. CHAMPNEYS, in reply, regretted that he was unable to show a living specimen. He did not doubt the existence of—indeed he had described—extensions of the mammary gland into the axilla. But the axillary lumps were of a very different nature, as he had shown in the paper. He was inclined to accept Dr. Creighton's view of their origin. These lumps were not perceptible before delivery, swelled after parturition, and again slowly decreased in size; in these features, and in yielding a secretion of milk, they differed altogeher from lipomata.

Dr. ALTHAUS communicated a paper on Paraplegia from Pott's Disease, and its Treatment by the Actual Cautery. The author related the case of a domestic servant, aged twenty, who had had rheumatic fever two years before admission to hospital, and painful paraplegia for about twelve months. The right lower extremity was more severely affected than the left. There was exaggeration of the superficial and deep reflexes and of the galvanic and faradaic responses of the nerves and muscles, and there were certain vaso-motor symptoms, while all forms of sensibility were perfectly normal. There was an angular deformity of the ninth and tenth dorsal vertebræ, the structures above the projecting vertebræ being thickened and indurated, with deficient flexibility of the spine. All the other organs and functions of the body appeared to be normal. The case was therefore diagnosed as one of caries, probably non-tubercular, of the bodies of the vertebræ, followed by external pachymeningitis and some degree of interstitial transverse myelitis. Medicinal treatment having proved ineffectual, the actual cautery was applied by Mr. Pearce Gould on both sides of the deformity, on four separate occasions, with the result that the patient, who had been unable to walk, sit, or stand, recovered, and was discharged cured seven months after admission. The author then discussed the mode of production of the pain, and of the motor, vaso-motor, and secretory paralysis, as observed in cases of Pott's disease, and distinguished three different degrees of pressure and of corresponding severity of nerve symptoms:—1. That in which only the spinal liquid was displaced, while the membranes and the substance of the cord were not interfered with to any perceptible degree; this explained the cases in which there was considerable deformity, but no pain or paralysis in the limbs. 2. That in which there was not only displacement of spinal liquid, but also a moderate degree of external pachymeningitis and interstitial myelitis of the white columns of the cord, caused by the contact with the diseased vertebræ, and accompanied with pain and paralysis of limbs, but without loss of sensibility or reflex mobility. Motion suffered more readily from pressure than sensation, because sensation was more easily conveyed along the nerve tubes, and would persist as long as only a portion of the nerve cells in the grey centre of the cord remained active, and after the posterior columns had been disabled. The case described belonged to this class. 3. That in which there was severe squeezing and consequent inflammation of the entire substance of the cord. In such cases we observed clinically all the symptoms of complete transverse myelitis *in loco morbi*. The author recommended an early resort to the use of the actual cautery in all cases of Pott's disease where symptoms of paraplegia are beginning to be developed. Under the influence of powerful counter-irritation the inflammation in the bones and the dura mater ceased, there was absorption of morbid products, and the compression and inflammation of the cord were relieved. Although there was probably always some degree of myelitis in addition to the pachymeningitis, the recovery of function could be explained by assuming that a considerable number of nerve tubes had not perished, and that when compression was removed these were enabled to resume their normal activity. When the third stage of the disease had once been reached recovery was plainly impossible; loss of sensibility was therefore a much more ominous symptom in cases of Pott's disease than paralysis.—Mr. G. D. POLLOCK had found the actual cautery of much value in a variety of cases of injury and chronic inflammation of bones and about joints. He related a case in illustration. The skin was percussed by a button heated to whiteness.—Dr. B. O'CONNOR remarked on the completeness of the recovery in the case recorded. Did Dr. Althaus consider that there was more advantage in the use of the actual cautery as compared with setons?—Mr. FITZROY BENHAM had seen several cases where rest had sufficed to cure the disease. If the paralysis did not improve in these circumstances, the disease was advancing. He agreed that where sensation was affected the disease was more advanced.—Dr. ALTHAUS replied that two large strokes were made by the sides of the spines. Formerly the cautery was used for disease of the spinal cord itself, and without any good effects, and had therefore fallen into disuse. The cautery certainly shortened the course of the disease in his case. He preferred it to the seton, as it was more speedy and less painful.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Fatty Tumours of Sole of Foot and Palm of Hand.—Abnormality of Colm.—Meningeal Hæmorrhage due to Aneurysm.—Pathology of Rheumatoid Arthritis.—Hydatid Tumour of Recto-vesical Pouch.—Colloid Cancer of Uterine Fibro-myoma.—Thrombi in Pulmonary Artery.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Mr. C. B. LOCKWOOD exhibited Congenital Lipomata of the Soles of the Feet from an infant aged thirteen months. They were symmetrical and had existed since birth. They were without a capsule, and the lobules of which they were composed were whiter and not so large as the ordinary fat of the part. Such tumours were exceedingly rare; the only others with which he was acquainted were described in the fourteenth volume of the Pathological Transactions by Mr. Gay. They had the ordinary structure of lipoma microscopically, and no special malignant tendencies, as Mr. D'Arcy Power testified. He also showed a Lipoma of the Palm of the Hand from a young lady aged twenty-four; it was removed by Mr. W. Adams; was probably congenital, though first noticed at three years of age.—Mr. ROGER WILLIAMS had seen five specimens of congenital fatty tumours, and one of these occurred in the palm of the hand; in none of his cases were the bones involved.—Mr. R. W. PARKER remarked that congenital lipomata were not encapsuled as a rule; they usually occurred in places where fat was not generally or but scantily found, as in the scrotum.—Mr. J. H. MORGAN described a case of tumour of the palm of the hand, merely a hypertrophy of the normal tissue of the part. He referred to a case of fatty

Digitized by Google

tumour removed by Mr. T. Smith from the pelvis of a girl, growing from bone.

Mr. LOCKWOOD also showed a specimen of Undescended Colon from an anencephalic monster. The colon was adherent to the right lobe of the liver, and the mesentery had failed to descend into the right iliac fossa. This descent of the colon did not take place till about the end of the tenth week; perhaps the occurrence of a peritonitis causing adhesion to the liver accounted for the non-descent of the colon. In his specimen the testicle had descended normally. With undescended colon the testicle also usually remained in the abdomen, as Geoffroy St. Hilaire and others had pointed out. Normally, there were bands passing between the testicle and colon, and it was supposed that the descent of the testicle was the efficient cause of the descent of the colon. The present case did not militate against this view, notwithstanding the facts.—Dr. NORMAN MOORE suggested that some peritoneal bands might be of non-inflammatory origin; could the natural bands referred to be the source of some of the peritoneal bands?—Dr. S. WILKS said that he had examined many stillborn syphilitic children, and peritonitis was not uncommon; it might occur in other conditions. Dr. Peacock had observed that some forms of congenital heart disease were of inflammatory intra-uterine origin. In a case in which Mr. C. Symonds had operated the cæcum was twisted on itself and thrown over to the other side, where it was fixed by adhesions, no doubt the result of peritonitis.—Mr. LOCKWOOD, in reply, referred to the meso-testis that sprang from the outer edge of the psoas muscle. He believed that many abnormalities were simply effects of actual intra-uterine disease, preventing normal evolution.

Dr. SEYMOUR SHARKEY read a case of Meningeal Hæmorrhage due to rupture of an aneurysm of the left middle cerebral artery. The patient, a married woman, aged fifty-one, was admitted under his care into St. Thomas's Hospital on Sept. 12th. Six months previously she had an attack of gout in the feet and attended as an out-patient. On Sept. 10th, whilst at work, she felt suddenly ill and vomited. She laid down on the bed for a short time and then tried to get up, but fell in her attempt to do so. She was then found to have lost the use of her right arm and leg, and she became unconscious and remained so until admitted two days later. She had right hemiplegia and hemianæsthesia and aphasia. She was drowsy, had a brown dry tongue and partial loss of control over the evacuations, and died on Sept. 17th, one week from the day on which she was taken ill. At the necropsy chronic renal disease and hypertrophy of the left ventricle of the heart were found. Slight extravasation of blood was seen in the membranes covering the anterior half of the left hemisphere of the brain and at the base; and a large hæmorrhage occupied and distended the left Sylvian fissure. It had formed a hollow cavity in the temporo-sphenoidal lobe, and had exerted great pressure on the other parts of the brain which form the boundaries of the fissure. It had separated the convolutions of the operculum from those of the island of Reil, and had flattened the lenticular nucleus and internal capsule, so much so that the knee of the latter was obliterated and its posterior and anterior divisions formed almost a straight line. The blood had not, however, ruptured the substance of the brain. The source of the hæmorrhage was a small aneurysm on the main trunk of the Sylvian artery. This case was an interesting example of the effects of pressure in interrupting the functions of the nervous system. The loss of sensation might perhaps be ascribed to the disorganisation of the hippocampal convolution, but the motor paralysis and aphasia seem to have no other explanation than the pressure of the effused blood upon the island of Reil and neighbouring convolutions and upon the central ganglia and internal capsule. It would have been impossible to distinguish the case clinically from one of hæmorrhage into the substance of the brain in the region of the internal capsule. In reply to Dr. S. Wilks, Dr. Sharkey said it was impossible to ascertain the condition of the special senses, owing to the patient's mental condition with aphasia.

Mr. ARBUTHNOT LANE referred to a paper in the Transactions of the Pathological Society, 1884, in which he had attempted to prove that Charcot's disease was rheumatoid arthritis altered by modifications in the vitality of the osseous and nervous systems. He now went a great deal further, and stated that in his belief rheumatoid arthritis was not a disease, and that the pathological conditions which we are accustomed to regard as the expression of this disease are but the result of force frequently or suddenly applied, as by a heavy blow. In previous papers, which were contained in the Transactions of the Medico-Chirurgical Society, Pathological Society, and elsewhere, he had shown that the transmission of pressure produced many important changes in the bones and joints. In the less movable articulations, as in those of the spinal column and pelvis, it caused the destruction of the articular cartilages or fibro-cartilages intervening between the bones and the formation of marginal osteophytic growth, so as to form large bosses or processes of bone, which frequently fused with similar processes from adjacent bones and so obliterated the joints. It also caused the development along the lines of tension of processes of bone, which extended along the ligaments or over the fibro-cartilages, and frequently united with similar projections from the neighbouring bones. He described instances of these conditions, all of which were regarded as products of the so-called disease, rheumatoid arthritis. In more movable joints, as in those of the extremities, pressure, exerted repeatedly and over a long period, produced changes identical in character with those just described, but altered in appearance by the greater mobility of these joints: these are the gradual removal of the articular cartilage covering the opposing surfaces of bone, an increase in the thickness of the articular lamella of bone, and its progressive eburnation on the complete removal of the cartilage. Coincident with these changes, bone is deposited on the margins of the articular surfaces, producing an extension of their areæ. The opposing eburnated surfaces of bone by their friction mutually destroy each other, and by this means a very considerable alteration in the shape of the articular ends is produced. To obviate, or rather to oppose, any displacement of the altered bones, a compensatory osseous growth is formed along the margin of the articular surface and frequently in the ligaments, and should the mutual trituration of the bones result in displacement, accompanying the gradual displacement, there is an abundant formation of new bone. The amount and rapidity of these changes vary much in different individuals, and depend on the vitality of the osseous system. If a movable joint be struck a violent blow, the changes produced are similar to those just described, but they progress with much greater rapidity. Instances of this last condition in the case of the hip-joint are sometimes described as rheumatoid arthritis due to injury, and in others as interstitial change in the neck of the femur, producing shortening. These changes are one and all described as rheumatoid arthritis, rheumatic gout, or arthritis deformans, and he maintained they are due, as he described them, to injury. The reason that so-called rheumatoid arthritis is so common in man as compared with the lower animals is that he so often bears burdens whose weights are transmitted at what is a great mechanical disadvantage, and his joints, as the hip and shoulder and the first metatarso-phalangeal, are much more exposed to injury than they are in the lower animals. In animals who carry or drag heavy burdens, as horses, pressure changes are frequently seen. This is less frequently the case with animals portions of whose bodies are exposed to violent strain in the pursuit of their prey, as serpents &c. Having, as he supposed, proved his point as to the identity of so-called rheumatoid arthritis with a condition which certainly cannot be regarded as other than physiological, he classified the results of the transmission of force under three headings, the first two of which he had already described:—1. The effect of pressure repeated very frequently and over a long period of the lifetime of an individual. 2. The influence of heavy pressure applied at one time, as by a heavy blow. 3. The effect of pressure exerted over many generations upon a part. This last effect of the transmission of pressure, which does not produce conditions whose character is far removed from rheumatoid arthritis, he believed to be a most important factor in the process of evolution, and he exemplified this by comparing the changes in the pelvis and lumbar spine of the coal-heaver with the similar parts of the mylodon, and with the fusion of the last lumbar vertebra with the first sacral, which is occasionally seen in man and not uncommonly in the higher apes. He then compared the condition of backward displacement of the fifth lumbar vertebra, which he has described, with a condition of dissociation of the first sacral vertebra in man, which he had found very frequently, and showed that these conditions were due to the similar transmission of superjacent force.—

Dr. NORMAN MOORE could not accept the view of the traumatic origin of joint changes in rheumatoid arthritis. In individuals suffering from emphysema or arterial disease the joints frequently showed degeneration of their cartilage, which changes were regarded as also related to age. In many members of the animal kingdom ankylosis of the joints occurred. Mr. Lane had quoted the case of the mylodon robustus, but the guillemot also exhibited similar changes that could not be attributed to strain or pressure. In his experience the sterno-clavicular joint was the least liable to present alterations of the kind in question.—Mr. LOCKWOOD criticised some of Mr. Lane's views. The feeble nutrition of afferent nerves was difficult to establish, and he asked whether the author still adhered to his opinion of the cause of fracture and ossification of the costal cartilages.—Mr. C. SYMONDS could not accept the author's hypothesis; he did not regard the changes spoken of by Dr. Moore as of a degenerative kind, for proliferation was their chief and earliest feature. He could not believe that rheumatic arthritis was simply due to chronic strain on the joints.—Mr. W. ADAMS dissented from the author's views, and agreed with those of Dr. Norman Moore; some constitutional cause was surely at work in the production of osteo-arthritis.—Dr. E. CLARKE alluded to the view put forward by Dr. Garrod, that the big toe being exposed to injury was the reason of its being the chief seat of local gout.—Dr. J. S. BRISTOWE also agreed with Dr. Moore that rheumatic arthritis was not the result of pressure. Bedridden patients sometimes developed the disease. He observed that Mr. Lane did not regard osteo-arthritis as a disease; if it were not, what was it?—Mr. A. LANE was fully aware of the facts and hypotheses that had been advanced; he would leave to the future the acceptance of his views which had in no measure been shaken by the observations made in the discussion.

Mr. ROGER WILLIAMS showed a specimen of Colloid Degeneration occurring in a Uterine Fibro-myoma, taken from a single woman aged forty-three. The specimen was referred to the Morbid Growths Committee.

Mr. E. H. FENWICK exhibited a Hydatid Tumour of recto-vesical situation. It occurred in a man aged fifty, who during life presented a large tumour in the left iliac fossa; it gave him much pain; the bladder and urine were healthy, but constipation was obstinate, though relieved by purgatives. At the necropsy a large bilobed hydatid cyst was discovered between the bladder and rectum; the upper lobe was of the size of a fœtal head, and the lower that of a large pear. A secondary cyst also existed in the liver. There were fifty such cases on record, some pressing on the bladder, and others on the rectum; they did not open into the peritoneum unless by accidental rupture. He believed that leakage from the hepatic hydatid cyst was more plausible than the theory of their subperitoneal origin.—Dr. NORMAN MOORE had examined two such cases in the post-mortem room; their existence was not suspected during life. In one, rupture into the peritoneum occurred, with sudden death; in the other, rupture, followed by peritonitis, ensued. There were no hydatids elsewhere in these cases.—In reply to Dr. Ernest Clarke, Mr. FENWICK said the patient died from the effects of a combination of morphia and drink.

Dr. CHARLEWOOD TURNER showed Thrombotic Masses in branches of the Pulmonary Artery, which he regarded as of similar nature to the fibrinous vegetations formed in the valves of the heart in consequence of valvulitis. The thrombotic masses were of varying size, some nearly two inches in length, and began at the bifurcation of large branches of the artery where the blood-current was certainly not slow. He believed that an endarteritis of the pulmonary artery was the cause of the thrombotic mass being deposited from blood, which had also become deteriorated from the normal by various diseases. The specimens were interesting when taken in conjunction with those of aortitis shown at the last meeting of the Society. The question also arose whether infarcts in the liver and spleen and elsewhere might not sometimes be due to the development of thrombi as the result of local endarteritis and consequent thrombosis, rather than to genuine embolism. It was interesting to note that in some infarcts no source of embolism could be discovered.

The following card specimens were shown:—Mr. Mansell Moullin: Primary Sarcoma of Spermatic Cord. Dr. Silcock: Glandular Epithelioma from the Lung of a Dog. Dr. Goodhart: Internal Rupture of Liver. Dr. Handford: Supernumerary Nipple in a Man.

HARVEIAN SOCIETY.

Bulbar Paralysis.—Peculiar Form of Choroiditis.—"Nodding Spasm" (Spasmus Nutans).—Cyanosis from Heart Disease.—Excision of Knee-joint.—Albuminuric Retinitis.—Left Lateral Hemiopia.—Dislocation of Crystalline Lens.

A CLINICAL evening was held on April 15th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair.

Dr. BROADBENT showed a case of Bulbar Paralysis. J. H——, a stonemason, was admitted into St. Mary's Hospital on Jan. 29th, 1886. He had served in India, and there suffered from syphilis, sunstroke, dysentery, ague, &c. One year before admission he had begun to lose his voice, and had difficulty in swallowing, the food collecting in the sides of the mouth, necessitating manipulation with the fingers, the saliva dribbling away. These conditions and a gradually increasing muscular weakness had continued, with occasional remissions, until admission, when he was found to be unable to speak except in a whisper, every syllable being produced by a long forcible expiration. The vocal cords were seen to be widely separated, and could only be partially approximated on phonation. The tongue was small and shrunken, and could be moved from side to side, although only partially protruded. There was impaired movement of all the facial muscles of expression, general muscular wasting, with paresis, traces of the reaction of degeneration, increased superficial reflexes, and good sensation. Since admission there had been a general improvement in all these symptoms, the chief trouble arising from the profuse amount of saliva which frequently blocked the pharynx and larynx. When shown, the condition presented all the foregoing symptoms, the patient complaining also of pain in the left side of the face and head, with occasional nausea. The expression of the face was fixed, the eyes being very bright. The sight, however, was impaired, the ophthalmoscope showing pallor of the centre of the discs and very small vessels. The pupils reacted to light and accommodation, but were somewhat contracted. Hearing was also impaired. The heart's action was weak but regular. Respiration chiefly abdominal. The patient walked with a stiff but steady gait, but had great difficulty in getting upstairs or in rising from a seat, owing to weakness of the extensor muscles of the thigh, which, in common with most of his extensor muscles, were wasted, and exhibited to a slight extent the reaction of degeneration. The superficial reflexes were exaggerated, and there were ankle and thigh clonus in the left leg. Sensation was complete. Treatment had consisted of rest in bed, with thirty grains of iodide of potassium daily.—Dr. MAGUIRE related a case of chronic polio-myelitis, with rigidity and excess of reflexes, in which the symptoms of bulbar paralysis showed themselves towards the end of the case. Sclerosis had been found spreading from the anterior horns to the lateral columns, and a microscopic hæmorrhage had been discovered in the nucleus of the vagus. There had been no renal disease in the case.—Dr. BROADBENT, in reply to questions, stated that the extent of previous antisyphilitic treatment of the case was not known. The larynx had probably been affected by the syphilis. Iodide had been given lately.

Mr. JONATHAN HUTCHINSON exhibited drawings of a Peculiar Form of Choroiditis, in which, with a very extreme degree of disease in the choroid, sight had been well recovered.—The PRESIDENT related a similar case which had occurred in association with locomotor ataxy.—Mr. JULER had seen a few such cases in which there appeared to be no trace of syphilis.—Mr. HUTCHINSON advocated the use of antisyphilitic remedies in all such cases.

Dr. STEPHEN MACKENZIE exhibited two infants, aged respectively nine and fifteen months, each presenting a series of more or less Rhythmical Movements of the Head, partly consisting of a nodding of the head forward and partly of a rotatory movement, the latter being more marked in one case than in the other. In each there was nystagmus, which, in one case, was almost entirely confined to one eye. The nystagmus was increased, or evoked if absent, by restraining the movements of the head. The nodding movements ceased during sleep. There were no ophthalmoscopic changes. In neither case was there decided evidence of

Digitized by Google

rickets. In both the nodding spasm came on without apparent cause. Dr. Mackenzie pointed out that they were examples of a rare form of spasm which had been well described by Henoch. It occurred especially during the dentitional period, and usually terminated spontaneously, often after the eruption of a tooth. Henoch drew attention to the association of movements of the eyes with those of the head as indicating the close anatomical relation of the roots of origin of the spinal accessory and upper spinal nerves, which supply the throat and neck muscles, with those of the oculo-motor communis, supplying the muscles of the globe.—Dr. BUZZARD described a case of rotatory movements of the head, with uniocular nystagmus. The fundus of the eye was normal, and the case improved under bromide of potassium.—The PRESIDENT thought that the movements were allied to those seen in the chorea of dogs, which had been shown to be due to affections of the anterior cornua.—Dr. GAIRDNER (Glasgow) observed that the cases were new to him. He related a remarkable case of nodding and rotatory movements of the head in a young girl, ultimately proved to be due to deception, which for years had defied detection. In these cases hysteria was out of the question.—Dr. BRISTOWE had never seen a case similar to those exhibited. Was the symptom the same as that sometimes seen in old people? He quoted the case of a boy, much given to tricks, who had adopted just such a nodding movement; and two other cases of movement of the occipito-frontalis, which had been described as nystagmus of the muscle. Both of these had recovered.

Dr. LAYCOCK exhibited a patient with marked Cyanosis, of congenital origin.—Drs. SANSOM, BROADBENT, and STEPHEN MACKENZIE believed the case to be one of congenital imperfection.

Mr. A. J. PEPPER exhibited a case in which he had performed Excision of the Knee-joint with marked success. An attack of erysipelas had complicated the case, notwithstanding the use of spray and gauze.—Mr. HUTCHINSON advocated the use of irrigation by a spirit and lead lotion in all cases of excisions of the knee, or of compound fractures and dislocations. By this means his cases had always been free from erysipelas, and wounds frequently healed within eight days.

Mr. JULER exhibited the following cases:—1. Albuminuric Retinitis, occurring in a woman during the eighth month of pregnancy. The patient had noticed her vision becoming dim about six weeks before delivery. The child was born at full term six weeks ago, but the vision was still very bad (⅔ and Sn. 6). The retinæ presented numerous large white spots with recent hæmorrhages, and there was some neuritis. The urine still contained one-eighth albumen. Was the renal affection induced by the pregnancy, and would the induction of premature labour have prevented the retinitis? In three previous pregnancies there had been no ocular symptoms. 2. Left Lateral Hemiopia, occurring in a woman aged thirty, who was attacked four months ago with slight paralysis, inducing partial loss of motion in the left arm and leg and total loss of vision over the left half of each visual field. There was no loss of any other special sense, or of ordinary sensation on either side of the body. The motor nerves had apparently regained their function, but the fibres of the optic nerves showed no sign of improvement. 3. Dislocation of Crystalline Lens in a man aged fifty. He had suddenly found the right eye misty whilst in the erect posture, but on stooping so as to bring his head between his knees he was able to read even small print. The lens could be seen floating in the bottom of the vitreous chamber during the erect, and in its normal place in the stooping, posture.

An interesting discussion followed.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a meeting of the members of this Association on March 28th, Dr. Goldie read a paper on "Some of the Difficulties that Medical Officers of Health have to contend with relative to Infectious Diseases." A discussion followed, in which several members joined. The reading of a paper by Dr. Wilson on "An Outbreak of Diarrhœa caused by Tide-locked Sewers" having been postponed, it was resolved that it was desirable that a conference of medical officers of health and others interested in sanitary science should be held during the Congress of the Sanitary Institute at York in September next, such conference to be called by, and on the authority of, the institute as part of the business of the Congress.

Reviews and Notices of Books.

A Treatise on Amputations of the Extremities and their Complications. By B. A. WATSON, A.M., M.D., Surgeon to the Jersey City Charity Hospital, to St. Francis's, and to Christ's Hospital at Jersey City, New Jersey, &c. Illustrated by upwards of 250 engravings and two full-page plates. Philadelphia: P. Blakiston, Son, and Co. Edinburgh: Young J. Pentland. 1885.

THIS work is stated to be the outcome of more than twenty-five years' devotion to the study of the history of amputations and to all the questions pertaining, directly or indirectly, to these operations. The first chapter deals with the history of amputations, and the author shows considerable research and careful reading. He gives an accurate and fairly full account of the gradual development of the art and science of amputation, and points out when and by whom the main improvements in older methods were introduced. This chapter contains much interesting information, and is very valuable for reference: it appears to us to be the most useful part of the whole book, as it contains facts not easily gathered elsewhere. The immediately succeeding chapters deal with the conditions affecting the results of amputations, the various methods of amputating, the instruments employed, &c. These subjects are treated at considerable length, long quotations from other authors, particularly English and American, being freely introduced. The fifth chapter is devoted to an account of special amputations, and is freely illustrated by woodcuts. We notice some omissions—such, for instance, as Roux's amputation at the ankle-joint, and Furneaux Jordan's method of amputation at the hip-joint. Both of these are well-recognised procedures, which certainly ought to have found a place in such a work as this. Again, although the preservation of the periosteum is mentioned in the historical sketch of amputations, we find no further reference to subperiosteal operations. In such omissions as these, and in the very free use made of the descriptions of other writers, we miss traces of a master hand, although it is impossible not to recognise the author's diligence and care. The treatment of amputation wounds is discussed in two chapters; all the methods now in vogue are described and fairly weighed, and Dr. Watson expresses his confidence in Sir Joseph Lister's method of dressing wounds. A long chapter of nearly 150 pages is devoted to a discussion of the selection and application of artificial limbs. This section is well illustrated, and contains much valuable information in regard to artificial limbs of all kinds. The concluding chapters are occupied with a consideration of the causes, symptoms, and treatment of the complications of amputation wounds, hæmorrhage, delirium, pyæmia, septicæmia, erysipelas, gangrene, osteomyelitis, and tetanus. The author has evidently laboured hard and conscientiously at his task, and has succeeded in supplying a want, but we cannot forbear expressing our opinion that a freer exhibition of the critical faculty would have greatly added to the value of the work.

Illustrations of Unconscious Memory in Disease, including a Theory of Alteratives. By CHARLES CREIGHTON, M.D. London: H. K. Lewis. 1886.

THOUGH the author has intentionally omitted to say anything of those diseased states where the application of the doctrine of morbid habit is "obvious and universally acknowledged," he has extended it in "unlikely directions," showing, for instance, that mesoblastic tumours are due to revived embryonic activity, that catarrh is a return to a more primitive kind of cellular activity, and that the so-called "stomach cough" is in reality the dregs of a former cold or irritation in the air-passages which may perhaps

Digitized by Google

have been forgotten. There is a most interesting chapter on Whooping-cough, which, whether agreed with at first sight or not, should start a valuable train of thought in the mind of the practitioner whenever a case or a number of cases of this affection comes under his observation.

"Many practitioners are sanguine in using remedies to stop the paroxysms from the outset. In what class of cases is that treatment successful? Writers on the subject do not usually distinguish one class of cases from another; or, if they do, it is in order to place in a 'spurious' class all the cases which do not suit the dogma of continuous reproduction of the specific disease by contagion. In my view, it is just those cases of whooping-cough caught by healthy subjects which are the spurious; while the real cases are those in which the paroxysmal cough is the sequel of a feverish catarrh, sporadic, epidemic, or belonging to measles." Dr. Creighton goes on to suggest that vigorous alterative or habit-breaking treatment is suitable for older and stronger children who have caught the disease from others, while in the younger children the paroxysms are a kind of postponed reaction, "bound to come out sooner or later, and the sooner the better."

A large number of other diseases are discussed in relation to unconscious memory—e.g., neuralgia, skin diseases, diabetes, and even syphilis and cancer. Some interesting remarks will be found on page 44 on the Hahnemannian doctrine of specifics. Altogether this little work of some 200 pages teems with interesting and suggestive points, and will well repay perusal even by those who might be disposed to take alarm at the highly philosophical "prologomena on memory and organic memory" which form the subject of the opening chapter.

OUR LIBRARY TABLE.

Elements of Practical Medicine. By ALFRED H. CARTER, M.D. Lond. Fourth Edition. London: H. K. Lewis. 1886.—This is a really useful and practical student's text-book, and has deservedly met with considerable success. It is written in plain language, and is by no means encumbered with detail, whilst all speculative reasoning is put aside. It is such works as this which are of the greatest value to the beginner in medicine, and of use to him in attending his first course of systematic lectures upon the subject. Having carefully studied these outlines, the student should then amplify his knowledge by the more detailed works, of which we have so many that are excellent—such as those of Roberts, Bristowe, Niemeyer, and Hilton Fagge,—his choice being determined by the needs he desires to supply, the time at his disposal, and the bent of his own mind. To the unambitious, and those who seek no other knowledge than can be available for examination purposes, it is fortunate that the smaller works, of which the present is an example, have been compiled with so much care; for it must be admitted that the student who knows these "Elements" well, and devotes himself to clinical work, will be possessed of sufficient knowledge to pass the ordinary standard of examinations.

Archiv für Anatomie und Physiologie, 1886. HIS, BRAUNE, und DUBOIS-REYMOND.—*Physiologische Abtheilung*, Heft. I. und II. This part contains—Stolnikow on the Estimation of the Blood-current in the Aorta of the Dog, with five plates; E. v. Fleischl on a Mikrostroboscopic Stimulus Research; W. Filehne on the effects of Xanthin, Caffein, and some Allied Substances; K. Hällstén on the Sensory Nerves and Reflex Apparatus of the Spinal Cord; G. Humilewski on the Influence of Muscular Contractions of the Hind Limbs on the Circulation of the Blood; J. Jegorow on the Influence of the Long Ciliary Nerves on the Contraction of the Pupil; and, lastly, the proceedings of the Physiological Society of Berlin, including essays by Christiani on the Excitability of the Respiratory Centre; Th. Weyl on the Relations of Cholestearin to the Terebenes and Camphors; Lehmann on the Functions of the Corpus Striatum; Benda on Spermatogenesis in Mammals; an account of some Demonstrations on the Ox-heart by Gad, and on the Termination of the Nerves of Temperature by Goldscheider.—*Anatomische Abtheilung*, Heft. I. und II. This part contains: Bechterew on a Special Constituent of the Lateral Columns of the Spinal Cord, and the Origin of the Fibres of the Fifth Pair of Nerves; Braune and Stahel on the relations of the Lungs to Ventilating Air Spaces, and to the Bronchi as Air-conducting Tubes; Stahel on the Relation of the Thickness of the Walls of Arteries to the Blood-pressure; R. Altmann on Improvement of Microscopes; A. Froriep on the Developmental History of the Spinal Column, and especially of the Atlas and Axis; Max Flesch, another case of Peculiar Division of the Internal Carotid Artery in the Skull; Strahl on the Formation of the Cloaca of the Embryo of the Rabbit.

The Rotifera or Wheel Animalcules. By C. T. HUDSON and P. H. GOSSE. Part III. Longmans, Green, and Co. 1886.—This part completes the first volume of the work, a work that may be expected to develop even during the period of its publication beyond the limits originally assigned to it. The authors state in their preface that their treatise contains more than 120 species which were unrecognised when Dr. Arlidge brought out his edition of Pritchard's excellent History of Infusoria; that nearly the whole of them have been added to science by the authors themselves; that about eighty of these new species, chiefly among the Ploïma, have been found by one of the authors during the last fifteen months; and that the other, by the discovery, among other remarkable forms, of Pedalion mirum has put beyond question the fact that the Rotifera in one point at least are closely linked to the Arthropoda. The plates in the present part include drawings of Microcodon, Sacculus, Asplanchna, Synchaeta, Polyarthra, Triarthra, Pteroessa, Pedetes, Hydatina, Rhinops, and Notops. The letterpress contains accounts of many new species, and is well worked up to present date.

Horse and Man; their Mutual Dependence and Duties. By the Rev. J. G. WOOD. Pp. 339. London: Longmans, Green, and Co. 1885.—The object of this work is to promote a more humane system of management of the horse. As it is intended for the use of all who possess or who have charge of horses, it is "couched in language which can be understood by all persons of ordinary education." The points on which the author particularly dwells are the present system of shoeing and the use of bearing-reins and blinkers. He would desire to see all horses ridden or driven unshod, and has collected a mass of information tending to show that this is not only practical, but desirable. Failing this, he strongly recommends the adoption of the "Charlier system," as being in all respects the most advantageous, and in this, as the result of considerable experience, we quite agree with him. He also writes strongly against the absurdity of the "hogged mane," and against the cruelty of the now nearly obsolete practice of "docking" and "nicking." He is also opposed to the generally adopted system of clipping. Although we do not coincide with the author in all his views, we can recommend his book to all who take a practical interest in horses, as containing many good suggestions, and as being likely to lead to a more humane and sensible treatment, a result to be obtained in some measure by a more effectual supervision on the part of the master. The book is remarkably well got up, the illustrations are good, and there is a copious index.

The Journal of Mental Science. April.—The original articles are:—Dr. Achille Foville: The Right of Reclamation of the Insane before the Civil Courts. Dr. E. M. Courtenay: Irish Asylum Dietary. Dr. Savage: Drunkenness in its relation to Criminal Responsibility. "Triboletes": The Psychological Bearings of the recent Matriculation Exami-

Digitized by Google

nation of the London University. There are many interesting "Clinical Notes and Cases," of which we specially mention Dr. Wiglesworth's case of Old Amputation of the Left Upper Arm associated with Atrophy of the Right Ascending Parietal Convolution, Dr. H. White on a case of Saturnine Insanity, and Dr. J. Mickle on some Abnormal Forms of Breathing.

The Journal of Heredity. Vol. I., No. 2. Chicago.—This quarterly is a most amusing production, being chiefly a collection of writings by various authors; the amusement comes in from the nature of the subject allowing the introduction of remarkable anecdotes, queer advice, and logical fallacies. Dr. Kellogg's article "Who may not Marry?" has much excited our organs of risibility; but, for all that, the advice given is based on sound principles: "Criminals should not marry; marriage between widely different races is unadvisable; persons who are unable to sustain themselves or a family should not marry; do not marry a person whose moral character will not bear the closest scrutiny."

The Journal of Physiology. Edited by MICHAEL FOSTER. Vol. VII., No. 1.—This part is entirely occupied with Dr. Gaskell's paper on the Structure, Distribution, and Function of the Nerves which innervate the Visceral and Vascular Systems, with four plates.

"Unicode": a Code of Cypher Words for Commercial, Domestic, and Familiar Phrases in Ordinary Use in Inland and Foreign Telegrams. Cassell and Company, Limited.—This telegraphic phrase-book aims at two particular qualities—viz., a low price and a universality of employment. The main features of it is the exclusive use for the cyphers of Latin words which are said to conform strictly to the regulations of the International Telegraph Conferences held in Paris, London, and Berlin. It is claimed that the confusion sometimes arising when the English words generally employed in existing codes for cyphers, read intelligibly, is thus avoided, and that the compilation having been made under the personal supervision of telegraphic experts of long experience, the cypher words are, from their telegraphic construction, the least liable to erroneous transmission by the operators. The cypher words are arranged alphabetically, and the phrases are likewise so arranged, having regard to what is in each the principal or key-word. There are some 120 phrases under the heading "health," which will be found useful as a means of conveying, economically and rapidly, to anxious friends at a distance the doctor's report on the state of the patient's health. At the end of the book is added a selection of cypher words which will never be included in the "Unicode" for permanent use with any specific phrases, but are intended only for private phrases to be arranged specially between individual correspondents. These, we think, might be made very serviceable to the busy practitioner. The employment of Latin words has in the "health" section occasionally rather an odd effect; for instance, the phrase "taken ill" is represented by the cypher word "dysuria"; "attack is considered not serious" by "diploma"; whilst "femur" means "very much better."

THE SUPPLY OF THE PROFESSION.

SIR LYON PLAYFAIR is not the only public man who has had exaggerated fears of not being able to fill the ranks of the profession. Accordingly we feel it our constant duty to keep our eye on the supplies, and we are bound to say that they are more than enough to meet the natural waste, and that they who enter the medical profession of the United Kingdom must reckon on entering a somewhat overstocked profession. The average annual deaths of registered medical men for ten years past have been 585, and the average annual number of additions to the Medical Register has been 1135, giving an annual excess of 550, which, after all further possible deductions, leaves a sure addition to the excess of the profession. The average annual number of medical men added to the Register in the last three years was no less than 1356. The same conclusions may be reached by studying an interesting return which is carefully prepared annually by the Registrar of the Medical Council—the "Medical Student's Register." From this we find that 1884 medical students were registered last year in the United Kingdom—910 in England 639 in Scotland, and 335 in Ireland. The tables and statistics of this Register, and other information it contains, are well worthy of study at the present time, when our legislators are invited to deal very superficially with the reform of our educational and examining system. Two things may be studied here: first, the quarters to which our students repair to pass those preliminary examinations which must be passed prior to the commencement of medical studies; and secondly, the medical schools which they favour for acquiring that education and those qualifications which are to fit them for their future profession. We have made a selection of the chief Preliminary Examinations, and state the number of students registered in 1885 on the strength of having passed them. Giving only the Preliminary Examinations, which were passed by thirty or more students, the facts are as follows:—

College of Preceptors	417
University of London Matriculation	181
University of Edinburgh Preliminary... ...	169
Royal College of Surgeons in Ireland	163
University of Glasgow Preliminary	155
Royal University of Ireland Matriculation ...	126
University of Aberdeen Preliminary	76
Royal College of Physicians & Surgeons, Edin.	70
Cambridge Previous	66
Apothecaries' Society, London	62
Faculty of Physicians and Surgeons, Glasgow.	45
Cambridge Junior Local	43

Only 53 entered the profession with the Arts Degree of any of the universities of the country.

The Medical Schools at which students entered (counting only those Schools with entries above 20) were as follows:—

University of Edinburgh	265
University of Glasgow	164
University of Cambridge...	90
University of Aberdeen	88
St. Bartholomew's Hospital, London	88
St. Thomas's Hospital, London	50
Carmichael Medical College, Dublin	50
Owens College, Manchester	49
Queen's College, Cork	49
Queen's College, Belfast	46
London Hospital	45
Guy's Hospital, London	41
University College, London	39
King's College, London	34
St. Mary's Hospital, London	32
Edinburgh (Extra-Academical Teaching) ...	32
University College, Liverpool	30
School of Physic, Ireland	30
Royal College of Surgeons in Ireland	28
Ledwich Medical School, Dublin	27
Charing-cross Hospital, London	25
Catholic University Medical School, Dublin ...	25
Yorkshire College Medical School	24
Westminster Hospital, London...	21
Bristol Medical School	20

The old method of commencing medical studies by pupilage with a medical practitioner is for the time being in some abeyance, but it is still recognised in the Regulations of the Council, and has been followed in England by 188 gentlemen, the names of whose masters appears in this Register; in Scotland by 11 gentlemen, in Ireland by 31.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1886.

IT is a noticeable fact, and as far as we remember an unprecedented one, that though a Medical Bill is before Parliament there is no sign of a meeting of the Medical Council. On all previous occasions this body has felt called upon to discuss the nature of such Bills, and even to make recommendations. On some occasions this has been done when there was less reason for such a proceeding than at present. But now when a Bill is before the House subordinating the Medical Council to an unprecedented extent to the Privy Council—in other words, compromising the independent government of the profession—the Medical Council gives no sign. There are also nine or ten medical corporations in the country, whose boast it is that they are the guardians of the interests and the honour of the profession. We do not hear that as yet they have made any communication to the Government indicating that in their opinion the profession is still capable of self-government, and that a Medical Council could easily be devised to which full powers might be extended of maintaining the standards not only of ordinary medical qualification but of medical graduation, and of punishing bodies which are unfaithful to their trust as ordinary examining bodies, or which deal in high titles and low examinations. The fact that Sir LYON PLAYFAIR thinks it necessary to introduce the Privy Council into his Bill between forty and fifty times is about the most damaging fact to the existing authorities, and to the system of twenty rival and competing examining bodies, which we can imagine. The obvious cure for this is to reduce the number of examining bodies and to abolish the system which allows most of them to send a separate representative to the Medical Council. Such were the main recommendations of the Royal Commission on the Medical Acts, composed of the most authoritative public men. Such have been the chief points aimed at by medical reformers for fifteen or sixteen years back. Yet the Bill which is before Parliament practically leaves things as they are. It may be said that there is a provision for recognising, if not securing, the decay of bodies that have outlived their *raison d'être*. So there is. But there is a counter provision for maintaining such bodies in perpetuity. For example, it cannot be doubted that we could most easily dispense with a corporation in each division of the kingdom, and that the Royal Colleges could amply do all the ordinary work required of medical corporations. In England, certainly, the Colleges have determined to leave out in the cold the Apothecaries' Society. But the Medical Bill has not even the courage of its immediate predecessor. It cannot disestablish the Apothecaries' Society. It provides in Clause 5 that in case a medical corporation represents to the Medical Council that it is unable to enter a conjoint scheme, the Medical Council may, of course subject to the Privy Council, appoint any number of examiners to assist at the examinations, and enable it to grant a diploma in all branches, and the right of registration under the Medical Acts. So that one of the possible results of the new Bill, if it becomes law, may be that we shall see the Apothecaries' Company with a few assessors appointed by the Medical Council, and a diploma of one-third the cost of that of the conjoint Colleges, competing with the Royal Colleges of England. Or we may see each corporation in the three divisions asking for the co-operation of the Medical Council for making its diploma complete and continuing the present rivalry of twenty bodies. Another defect of this Bill is that it does not make any attempt to deal more stringently with the great evil for unqualified practice. But in the present Medical Bill no attempt is made to amend the penal clauses of the Act of 1858.

We shall be told that this Bill concedes Direct Representation, and ought to be gratefully received by the profession. It is high time the profession was represented in a Council which it entirely maintains, which has the judicial power of erasing names from the Medical Register, and which, finally, has often shown the want of members familiar with the educational needs of the medical practitioner. But we cannot admit that the addition of four direct representatives to a Council already so big, and so bad in its constitution, will do any adequate good. The Bill is meant to please everybody, and, like all such Bills, it is weak and nearly worthless. It remains to be seen whether the medical members of the House will apply any adequate criticism to the measure, or whether it is to pass like so many other timid and powerless Bills. There are members of the profession in the House who could rise above party or corporation standpoints. The Bill does not pretend to give any power to the Medical Council in the matter of the standards for medical *graduation*, which, as well as the standards of mere competence, are of great consequence to the public and the profession. Without such provisions we may see a general levelling downwards of all the examinations and the degradation of medical graduation.

THE Gulstonian Lectures of the present year covered very wide ground, and touched on most of the problems that the motor side of the nervous system presents for consideration. The motor area of the brain with its appendages, and the similar apparatus of the spinal cord, possess a potentiality for spasmodic disorder which Dr. SHARKEY certainly did not over-estimate. The spastic states that result from disease of the all-important pyramidal tracts have received of late years so much clinical and pathological illustration, that we seem in regard to them to have really acquired some definiteness of information. The production of involuntary or spontaneous movements is an etiological subject which, though in a measure the exact antithesis of that of paralysis, nevertheless cannot profitably be studied apart; for the tendency of all ancient and modern research, both experimental and clinical, is to demonstrate that the two seemingly opposite states are dependent on one and the same morbid process. This notion has been variously expressed by different authorities at different times and in accordance with various circumstances, but none of the expressions appear to us to be more illustrative than that, we believe, of Dr. BROADBENT: Movements are half-way houses to

Digitized by Google

paralysis. The old authors' phrase, "irritable weakness," could not have been understood by them so thoroughly as by us, for we have the light of modern physiology to aid our conceptions, but the phrase contains the same germ of truth. The external manifestations of kinetic energy, far from being signs indicative of great potential powers, may be regarded as evidences of an internal instability of molecular processes, from "whose mouths the bits" can be too readily disengaged.

In the region of movements, physicians, like all physiologists, have long distinguished between the apparently continuous muscular contraction and the evidently intermittent spasm, to which the terms "tonic" and "clonic" are respectively applied. Whether there is any essential internal difference between the two forms of spasm is a question that still remains unanswered. It is possible that the problem may be solved in two opposite directions, in accordance with possible differences in the cerebral and spinal motor apparatus. The motor discharging elements of the spinal cord may conceivably emit their energy in a practically continuous fashion, as we may assume they do in the maintenance of normal muscular tone; but such a constant liberation of energy would not harmonise completely with all that we know of the mode of discharge of motor nerve elements; and we have in the phenomenon of tetanus a continuous muscular contraction that is well known to be maintained by regularly interrupted impulses. Further, SCHAEFER and HORSLEY have formulated a law to the effect that nerve motors have a normal rate of discharge of about 8 (or some multiple thereof) per second.

Dr. SHARKEY believes that the chief offender in the production of spasm or any variety of abnormal movement is the pyramidal tract, which includes the cerebral motor centres and their downward paths. On Dr. SHARKEY'S teaching—and we confess to a sympathy therewith,—if the practitioner comes upon a case of tremor, tonic spasm, clonic spasm, coördinated involuntary movements, or tetanic seizures, the chances are that the cerebral motor or pyramidal tract rules the situation—is the etiological master of the morbid phenomena. It is worth while for a moment to ask what all this amounts to. At first sight it might not appear to be a great assertion to make. But a little reflection alters the apparent aspect, and discloses a generalisation which might have been a truism were it not for the fact that so many other explanations have been offered concerning the production of "involuntary," or, as we prefer to say, "spontaneous," movements. A superficial thinker might say: "You assert that all, or nearly all, movements are the result of some disturbance of the pyramidal tracts. Well, there is nothing novel or startling in that, for we have for some time known that there is a motor apparatus in the brain, and if the movements do not originate in that, where should they be initiated?" Carrying this train of thought a little further, such a one would urge that it does not matter whether the impulse is a normal one (the will and ordinary automatism), or an abnormal stimulation, such as hæmorrhage, sclerosis, tremor, and the like. The production of normal movements is probably a question of inhibition. The "way out" of cerebral impulses through the motor area and pyramidal tract may be regarded as the path along which inhibitory impulses go to the spinal motor centres and set free normal movements which are there "represented." It is probable that the causes of disease act in a similar though irregular manner; they "let go" in a disorderly fashion the spinal motor centres, and so, to use Dr. HUGHLINGS JACKSON'S words, we have a "permitted hyper-physiological activity." But if Dr. SHARKEY'S views are correct—and we must confess that with certain qualifications we are disposed to accept them—they have been extricated from much entanglement by his own clear, steady, and judicious intellect. Let us look into this matter a little more closely. Dr. HUGHLINGS JACKSON believes that cerebral rigidity is due to unopposed cerebellar influence, and that cerebellar rigidity, tetanus, and tetanic seizures in cerebellar disease are the outcome of unantagonised cerebral influence. The spinal motor centres are coördinately innervated from the two regions, cerebellum and cerebrum. Dr. SHARKEY has examined this view, and does not appear to share in it. He points out, as Dr. HUGHLINGS JACKSON has truly observed, that the tetanic seizures of cerebellar disease only, in general, accompany tumours of the middle lobe of that organ, and this apparently only when the tumour is large enough or hard enough to press on the pons and medulla. If this fact be granted, then it is plain that the convulsive seizures can, according to all that we at present know, only be caused by an irritation of the grey matter of that region or by some interruption or damage to the pyramidal tracts. Dr. SHARKEY inclines to the latter view. The convulsive centre of NOTHNAGEL lends a kind of support to the former. But what shall we say when a tumour situate below the medulla oblongata is associated with similar tetanic seizures? It must be admitted, with but slight precautionary reservation, that the pressure or damage to the pyramidal tracts is the cause of them. This explanation is not, however, the whole matter. In the early stages of tumours of the middle lobe of the cerebellum tremors with paresis may be observed. The lecturer suggested that the mechanism of their production is identical, and differs but in degree from that of the causation of rigidity or tetanic seizures. If the pressure on or damage to the pyramidal tracts be slight, we should expect a mere interruption, or an imperfect passage of normal impulses to spinal motor centres, and so tremors would result; a further degree of pressure or damage would lead to permanent rigidity; and if the pressure or damage were liable to variations, tetanic paroxysms might result. The theory is ingenious, is simple, and must be admitted harmonises with ascertained facts. To sum up, we may assert that any organic disease of the cerebral motor area and pyramidal tract, provided it damage the essential protoplasmic elements, will give rise to some form of spasm. Cases of congenital absence of motor convolutions, where the pyramidal tract does not develop, support the view that it is not a question of irritation by sclerosing processes, but rather a "letting go" of the spinal motor centres, a removal of inhibition, a permitted hyper-physiological activity of the spinal motor centres. It has been argued that if this were the real mechanism of rigidity, then any sudden rupture of the pyramidal tract should be immediately followed by rigidity. But apart from the fact that the rigidity has

Digitized by Google

occasionally been observed to come on very rapidly, Dr. SHARKEY suggests that the spinal motors, long accustomed to restraining influences, may take some time to get rid of their organic memories, and this is a process that would require time, during which the centres are gradually relieved from the burden of their former masters. We know that usually an increase in the knee-jerks precedes, as also does the phenomenon of ankle-clonus, the appearance of rigidity in most cases of hemiplegia due to rupture of pyramidal fibres. But there may be other plausible explanations. For example, it may be that the hæmorrhage causing hemiplegia replaces for a time in an imperfect manner, by stimulating or irritating the divided ends of the pyramidal fibres, the restraining influence of the motor centres. And it is certain that in some forms of disease of the pyramidal tracts deep reflexes are not at first increased, but rather diminished. Here we might suppose that some influence is exerted on the pyramidal tracts that does more than replace the normal inhibition—in fact, constitutes a more powerful restraint. Another interesting matter touched on was the precise meaning of increase in the knee-jerk, the explanation that he and others hold being that reflexes from tendons and muscles may have a period of latency much shorter than ordinary reflex actions. Another point referred to in the lectures was the possibility of the production of spasm from disorder of the spinal motor apparatus, including its afferent and efferent nerves. Most physicians will probably agree with the lecturer in thinking that mere irritation of the afferent nerve is an infrequent cause of spasm; the centre itself either is or soon becomes under the influence of afferent stimulation, in a state of over-activity. Again, although physiologically it is easy to understand that various kinds of stimulation of the peripheral motor nerves may produce spasm, yet pathologically this process does not appear to be of very common occurrence. The subject of functional spasm is one of the greatest interest, and in the progress of civilisation likely to become still more important; for as civilisation advances the motor as well as the sensory processes of the cerebral, as opposed to the spinal apparatus, become more and more developed and strained. In this relation the connexion between hysteria and neurasthenia naturally arises, at least in regard to the motor disorders which are described under these names. Let us look with Dr. SHARKEY once again at the pyramidal tracts, and contemplate the possibilities of their "functional" disease. It is not unreasonable to suppose that under various conditions, which need not here be specified, the nutrition of the pyramidal tracts, including their motor centres, may be lowered or disordered. Hence the various neurotic and hysterical spasms. There is another department of this question that also requires elucidation. The motor cells in the cerebral cortex govern the nutrition of the axis cylinders composing the essential part of the pyramidal tracts; are we to believe that the nutrition of these fibres is equally well provided for throughout their whole extent? Is it not possible, as Dr. GOWERS implied in his address read before the Medical Society of London, at their very terminations, being remote from the centres of nutritional energisation, are more liable to functional derangement? This view was the one Dr. GOWERS adopted in the explanation of hysterical spastic paraplegia and the like. These terminations of the pyramidal tracts are his local inhibitory centres. But truly the subject is inexhaustible, and we must take leave of the present successful Gulstonian lectures by drawing attention to the comprehensive view of Dr. SHARKEY that organic as well as functional disease of the pyramidal tracts is the chief cause of spasm from chronic nerve disease.

OF late years there have been many schemes for the sanitary improvement of dwelling-houses. Some have been accepted as worthy of serious consideration, others have not been regarded as coming within the scope of practical egislation, but they are all nevertheless signs of a growing feeling that houses which are intended as dwelling-places for human beings should be so constructed as to afford reasonable opportunities for the enjoyment of health by their inmates. This was particularly shown by the Housing of the Working Classes Bill, which proposed to extend to unfurnished houses the provision which already relates to furnished houses—namely, that there should be an implied warranty that such houses, when let, are fit for habitation. It is true that this clause did not become law, but nevertheless it was accepted so far as relates to certain houses occupied by persons of the working classes. There is not much probability that these people will, without assistance, avail themselves of the opportunity this Act affords for obtaining compensation when their health has suffered from the condition of the house which they have rented, but the recognition by the Legislature of the principle embodied in the Act is one of the most important of recent advances in sanitary law.

Certain enthusiastic sanitary reformers desire to go much beyond this point, and it has even been suggested that every dwelling-house and other building shall be certified as to its proper sanitary condition, and that the duty of procuring such certificate should be imposed upon the owner or occupier. Such is the proposal of Mr. MARK JUDGE, who has even gone so far as to shape his ideas in the form of a Bill. We doubt much if such a suggestion will be seriously entertained; it has only to be recollected that there are in England and Wales upwards of five million dwelling-houses apart from other buildings, and that the cost of obtaining a certificate would probably not be less on an average than one or two guineas for each house, to show the practical impossibility of such a scheme. It is difficult to estimate what expenses would be incurred in the improvement of houses for which a certificate could not be obtained without alterations, but it is obvious the sum of money needed for the purpose would be a serious obstacle to the acceptance of such a measure. It might, too, be objected that it is unfair to mulct the owner of a house in good sanitary condition in the expense of obtaining a certificate which for him can serve no good purpose; under these circumstances it is the surveyor rather than the householder who would be benefited.

There is nevertheless very much need for the more active enforcement of the law with regard to newly built houses, and this is particularly noticeable in the metropolis, where considerable legislative powers have been conferred upon the vestries and upon the Metropolitan Board of Works. It

Digitized by Google

is no exaggeration to say that, with few exceptions, these bodies do not concern themselves to any greater extent with the drainage of a house than to see that the house drain has a communication with the sewer, yet the vestries have since 1855 had full powers to order the drainage to be made in such direction, manner, and form, and of such materials and workmanship, as the vestry shall order. As a result of this negligence drains are laid which leak at the joints and saturate the soil with sewage, no provision whatever is made for their ventilation, and apparatus is daily introduced into London houses which local authorities are urged to prohibit by the model bye-laws of the Local Government Board.

But all the fault does not lie at the door of local authorities. If amusement is legitimate in regard to conditions so deplorable, a paper by Mr. FRANCIS VACHER, the medical officer of health for Birkenhead, will supply it. Mr. VACHER gives an instructive account of examples of negligence and ignorance in the work done by artisans belonging to the building trades. It is a paper we would commend especially to working men, for the writer clearly shows that the artisan is no less a sufferer than the employer for whom he works, or than the occupier of the unhealthy house he has assisted to build. Mr. VACHER pleads for the better supervision of buildings by local authorities and their officers, and recommends the adoption of a course which would enable the uninitiated householder to protect himself by the employment of skilled workpeople. He would open in every centre of population a register which should contain the names of those workpeople who were known to the guilds of their trade to be properly qualified. The Plumbers' Company have resolved to establish "a system of registration in the City of London and seven miles thereof," and a register for qualified plumbers was opened on March 1st. Londoners at any rate will shortly be able to know to whom to trust their plumbing, and it may be hoped that other trades will follow the example which is set them, and that it will at last be possible to ensure that money spent on sanitary improvements will be laid out to the best advantage. The increased liability of landlords for the condition of the premises which they let renders it imperative that they should, in their own defence, employ those who may be trusted to preserve them from actions for damages, and will make the enforcement of sanitary law more acceptable to that numerous class of property owners who now influence local authorities.

Two very interesting cases of Bullet Wounds of the Brain successfully dealt with by operation have been recently reported by American surgeons. The first and more important is reported by Dr. FLÜHRER, one of the visiting surgeons to the Bellevue Hospital, New York. A young man, nineteen years of age, was admitted under his care for a bullet wound over the centre of the forehead. The injury was self-inflicted, and was immediately followed by unconsciousness, which lasted for three-quarters of an hour, after which the patient rose and walked some distance; then he became aphasic, and on admission to the hospital, soon after, was semi-conscious, having paralysis of the right side of the trunk and right limbs, and hyperæsthesia on the left side. After all preparations had been made to conduct the operation aseptically, the scalp was turned aside and the opening in the skull enlarged. Profuse hæmorrhage ensued; this was partly from the superior longitudinal sinus and easily controlled, and partly from a wounded branch of the anterior cerebral artery, the securing of which entailed great trouble, and was only achieved after the loss of a considerable amount of blood. The next step was to explore the track of the bullet through the brain by means of a large probe. The ragged opening of the entrance of the bullet was seen in the first frontal convolution, just at the inner edge of the hemisphere. The probe passed back and slightly to the left for about six inches, when a soft resistance was detected. With the probe *in situ*, a spot was marked on the scalp where its end would emerge if projected. Over this spot the scalp was reflected and the skull trephined. The dura mater, which was entire, was incised, and a little dark blood beneath it allowed to flow out. The opening in the skull and dura mater was enlarged in the supposed direction of the bullet until the finger could be passed in. A slight resistance was then felt in the brain. Instead of exploring this, more of the skull was cut away until a rent in the pia mater was exposed, with a quantity of torn brain-matter lying over it. Into this opening a probe was passed, which struck the bullet at the depth of an inch, and with small dissecting forceps this was then removed. Subsequently the probe could be passed quite through the brain from the anterior to the posterior wound, and into this tract a drainage-tube was passed. The entire operation lasted "about four hours." The subsequent history of the patient may be briefly summarised. A hernia cerebri developed at each wound, but neither of them grew fast or extended rapidly, and eventually both shrank; the wounds healed up, and the patient was restored to health. The right-sided paralysis and the aphasia passed off, and the man resumed his work in a butcher's shop. Subsequently he received a severe blow upon the anterior scar, felt acute pain, and then noticed spasm of the flexor muscles of the right arm and leg, which spread over to the left side. These symptoms recurred once. Under the influence of bromide of potassium the patient had remained free from any bad symptoms for fifteen months at the time when the report of the case was published.

Dr. FLÜHRER founded the treatment he pursued in this case upon the well-known fact that bullets entering the brain very frequently traverse it, and glance off again from the interior of the skull. He therefore advises that when a bullet is known to have entered deeply into the brain, the line of its track should be marked by carefully introducing a probe, and that the skull should be trephined at the spot where the ball will have struck it on the interior; from this second aperture the deflected course of the bullet can be easily traced, and through it the bullet can be extracted. The suggestion is a bold one, and without such a success as Dr. FLÜHRER achieved in the first case in which he practised it, surgeons would probably long hesitate before adopting it. It rests, however, upon a solid basis of fact, and, further than that, the double opening in the cranium is of great advantage in enablir the surgeon to have thorough drainage of his wound

Digitized by Google

very important consideration. Unfortunately the effects of a bullet wound of the brain vary within wide limits, not only with the region injured, but with the number and size of the vessels torn across. In many cases the condition is complicated with severe internal hæmorrhage. Where, however, there is no reason to suspect this, and the case appears to be uncomplicated, Dr. FLÜHRER'S suggestion is well worthy of the fullest consideration. Cerebral surgery is in its infancy; the results already attained have shown that it would not be wise at present to set any limits to its development, and we may therefore hope that even penetrating bullet wounds of the brain may prove to be amenable to surgical measures.

The second case to which we would allude is recorded by Dr. C. F. MACDONALD in the April number of the *International Medical Journal*. The patient was a convict who had received a bullet wound of the skull three or four years previously, and had become insane. A scar over a depressed fracture of the skull was detected 1¾ in. above the edge of the hairy scalp and ⅜ in. to the right of the median line, over the right first frontal gyrus, at the junction of its anterior and middle thirds. Pressure upon this spot caused intense pain and "violent bodily agitation." It was determined to explore the seat of this injury, and for this purpose the scalp was reflected, when an aperture in the skull was found, closed over by firm membrane; through this a hypodermic needle was passed in four directions, and on the last occasion clear serous fluid rose into the syringe, and in this way nearly two drachms of the fluid were withdrawn. The wound was then closed. In less than three hours after the operation the man was able to give a clear account of the injury and of his subsequent career, and all symptoms of insanity had vanished. From this time he advanced to complete recovery. Dr. MACDONALD considers that the fluid was contained in a simple serous cyst, as it did not contain any evidence of hydatids or of old hæmorrhagic or inflammatory effusions. Unfortunately the pathology of cysts of the brain is quite obscure. The case, however, is a great encouragement to interfere surgically where cerebral symptoms supervene upon a head injury, even although years may have elapsed.

"ALL work and no play maketh Jack a dull boy"; and yet if Jack be not constitutionally bright and resilient in his temperament he can make very little use of an occasional and brief holiday. Theoretically it is good to stop the machinery now and again and give its bearings time to cool down; but practically this stopping the works and setting them going again takes a great deal out of the apparatus in the way of additional friction. Who among us does not feel so much upset and thrown out of his swing by the enforced holiday—which is just long enough to break the rhythm without being sufficiently long to give a lasting sense of relief—that he sometimes doubts whether the one or two days' respite from routine work is not too dearly bought, when all the trouble and worry of preparing for it, and afterwards making compensation for the delay or neglect of daily duties, are taken into account?

The value of a holiday ought to be estimated on the basis of what it actually does for the worker. Is he the better for it in mind and body a while after it has been enjoyed? We have always contended that public holidays which involve the conversion of our cities into places apparently deserted are mistakes. If Sir JOHN LUBBOCK had only contented himself with bringing in a Bill to compel employers to give their servants a fixed number of days in the year for leisure and enjoyment without specifying the particular days to be observed, he would have conferred a boon on the community of serving folk of all classes without needlessly increasing the number of dead points to be overcome by extraordinary efforts. As it was, we had fifty-four breaks in the annual routine of business-life among Englishmen, and it may have been scarcely worth while to add to the number, particularly as it was, is, and we presume ever will be, foreign to the spirit of English Rule—albeit that is becoming each year increasingly *paternal*—to provide anything in the shape of public entertainment for the people. It is, however, useless to regret what has been done in the matter of Bank Holidays. That their institution was well-intentioned no one for a moment questions; our only doubt is whether the benevolent idea might not have been less inconveniently and more effectively carried out.

For the relief, even momentary though it be, of minds jaded with the monotony or wearied with the tension of daily work, and of bodies aching for the repose of certain groups of muscles, holidays doubtless have their direct advantages. Their chief value is meanwhile probably collateral. They afford opportunities for the stimulation of fresh cerebral centres by diversion of thought, the use of other groups of muscles than those habitually exercised, and in many instances an excursion among new surroundings, which may refresh the sense organs and supply the thinking part with additional material, brought before it in the pleasantest of all ways, by observation and experience. There is also something gained by fresh air and travel, hurried though it be. Physically and psychically, the holiday may be made to fulfil a useful purpose if only it be wisely used. We are not of those who conceive that life must needs be one long strain of duty. There may very properly be seasons of relaxation; or, to put the same remark in other words, the day's duty may, occasionally at least, consist in duty to self—that is, the higher, inner, and true self. Unfortunately there is nothing English men and women so little understand as how to "enjoy themselves." Children have the advantage of us in this respect. The art of *playing* is lost before the average mortal attains to middle age. Perhaps the very wisest and best thing to do would be to make these holidays children's days: to refer the whole question of holiday-making to a committee of young people, none of whom should be over twelve years of age, and to surrender for the particular period determined by the "holiday" the disposal of time and the selection of ways and means to those with whom "enjoyment" is an integral part of existence, and whose birthright it is to be able to make merry without wantonly sinning against light and conscience. Father and Mother Multitude might not altogether like the *vice versâ* experience of being subjected to the tyranny of their own children; but the adverse position would not be a permanent one; and we are disposed to think that, except in such specialties as "hard-bake" and "tip-cat"—which exacting and perilous amusements might be eschewed,—the gain to health of body and mind from a good round of playing and sight-seeing such

Digitized by Google

as any well-constituted child mind would devise would be greater than that secured by the majority of our adult schemes and conceptions.

Everything depends on the use made of the holiday, and to this condition attention needs to be more than commonly directed. Speaking generally, we should say that the very smallest practicable amount of good is actually got out of these holidays by the majority of the population. The state of the streets shows only too obviously how large a proportion lose rather than gain by the cessation of labour. The enjoyment of a holiday presupposes a certain capacity for utilising leisure which probably can only be developed by experience. Perhaps in the next generation English men and women may have come to possess the essentials for this self-help in the task of recreation. Meanwhile something may be accomplished by the serious consideration of a business which certainly requires an apprenticeship—that of "being happy." We sometimes regret that there is so little happiness in life. Depend upon it, there is just as much as we ourselves put in, and not a particle more. Those who would find the world a place of peace, and health, and happiness for body and mind must themselves make it so.

Annotations.

"Ne quid nimis."

THE SANITARY CONDITION OF CLERKENWELL.

MR. JOHN HAMER, the Honorary Secretary to the Mansion House Council on the Dwellings of the People, has addressed to the editor of *The Times* a letter which strongly supports the opinion we have ourselves expressed, that the inquiries now being held by Mr. Cubitt Nichols in no sense properly fulfil the intentions of the Royal Commission on the housing of the working classes, when they recommended that a sanitary survey should be made of the different metropolitan districts. Mr. Hamer points out that Mr. Nichols admits "the almost literal accuracy of the complaints made by the Council with regard to 464 premises" which came under their notice as the result of a month's inspection. Mr. Nichols appears to have extended his own inspection only to some fourteen more houses, and yet upon facts like these Mr. Nichols reports to the Home Office respecting the parish with its 7825 uninspected houses, and with its 475—the only ones challenged—found to be bad, "I do not consider the parish to be in a bad sanitary condition." We have no hesitation in stating that we believe if a report had been presented to the Local Government Board by any of its medical inspectors which had not more reason for the conclusions which it contained, it would not have been accepted by that Board. The fact is but too evident that the meaning of the words "sanitary survey" has not been appreciated. The duties and powers of the vestry do not appear to have been sufficiently considered or understood, for the report does not go far beyond an inquiry into the question whether certain statements emanating from the Mansion House Council are well founded. We have already expressed our appreciation of the work which this Council has done, but we cannot acknowledge that any inspection a voluntary association may undertake ought to be permitted to replace the detailed inquiry which should be made by an inspector of the Government. The government of London is too complex to be immediately understood, and in all probability the failure we have indicated is due to this circumstance. In another column we have referred to the powers the vestries possess to ensure the proper drainage of new houses. Have these powers, we would ask, been exercised by the vestry of Clerkenwell? There does not appear to be a single line in Mr. Nichols' report which gives any information on this all-important subject. It would be possible to show, in regard to a number of other points, the insufficiency of the inquiry, and we cannot but regret the loss of an excellent opportunity for learning with thoroughness the sanitary condition of London and the administrative capacity of its local authorities. That the inquiry will be of service we do not doubt, but we fear that the good it will do will be limited to the time any district is the subject of observation; and certainly, so far as we understand the intention of the Royal Commission, a golden opportunity is being lost.

THE SEASONAL PREVALENCE OF PNEUMONIA.

WE are indebted to Dr. Seibert of New York for having more than once directed attention to the close relation existing between those meteorological conditions which favour catarrhal affections and the occurrence of acute (fibrinous) pneumonia. At the present day, when the specific nature of this disease is receiving so much confirmation, it is especially useful to have the question viewed from another side. In his latest contribution to the subject (*Berl. Klin. Wochenschr.*, 1886, No. 17), Dr. Seibert affords conclusive evidence of the above-named connexion. His material was obtained by a collective investigation of returns furnished by members of the New York Medical Society, from March 1st, 1884, to March 1st, 1885. They comprise 768 cases of primary pneumonia, distributed in the various months as follows: January, 71; February, 140; March, 103; April, 73; May, 55; June, 37; July, 26; August, 25; September, 43; October, 62; November, 65; December, 78. A comparison with the average temperature of these months shows a striking correspondence between the lowness of temperature and prevalence of pneumonia; and a similar correspondence is manifested with respect to rainfall, except in the summer months, when, in spite of great humidity, there was a minimum of pneumonia. It is also shown that the prevalence of bronchial catarrh closely coincided with that of pneumonia. Dr. Seibert has not, however, been contented with these general monthly returns, but has placed side by side the results of daily meteorological observations and the date of occurrence of cases of pneumonia during each month of the year. The chart compiled from these data for the month of February will be found in his paper; and it is remarkable how closely the onset of pneumonia follows upon days in which there were combined low temperature, excessive humidity, and high winds. Without attempting to give examples of these relations, it must suffice here to allude to the conclusions at which Dr. Seibert arrives. These results are to the effect that the varying prevalence of the disease can be explained by certain meteorological states which favour its occurrence. These conditions are a low and falling temperature, an excessive and increasing humidity, and high winds. When any two of these factors concur, pneumonia prevails to a greater extent than when only one of the factors is present; whilst if all three factors are in operation, then pneumonia is exceptionally frequent, the frequency lasting as long as the meteorological conditions obtain. The same states of weather favour catarrh, and catarrh predisposes to pneumonia. That pneumonia is more prevalent in spring than in autumn is due partly to the greater liability to exposure after residence in hot and ill-ventilated rooms during the winter, as well as probably to the greater humidity of spring. Finally, the author does not wish it to be inferred that these meteorological conditions are the sole

Digitized by Google

factors at work in exciting pneumonia; his opinion rather is that by exciting catarrh they render individuals more vulnerable, and susceptible to the influence of the pneumonic virus. In this way his observations can still be made to harmonise with the doctrine of the specific nature of pneumonia.

THE NEW ASYLUM FOR LUNATICS IN MIDDLESEX.

WE must disclaim the least thought of influencing the Middlesex magistrates. They are far too conscious of the worth of their own opinions to care a cent for ours. We have often tried to induce them to look at matters from a point of view even slightly different from that which they have elected to take, without even a suspicion of success. We doubt whether there exists a power which could, by the most stupendous exertion, convince a Middlesex magistrate against his will, and, if there be, we are perfectly certain the worthy magistrate so convinced would be of the same opinion still. Not even in matters strictly medical do the members of this remarkable and interesting board yield place to the doctors. What it takes ordinary mortals many years of hard study to master, comes to a Middlesex magistrate, the moment he is raised to the Bench, as by inspiration. Certain of their number have as good as told us this, and so impressed have we been that it has set us thinking whether a short way of settling the medical education question would not be to abolish all the colleges and schools, and simply move the Government to make additions to the Middlesex board every year as the public necessities called for new medical practitioners. This being so, we must apologise for the impertinence of suggesting that, as it is decreed that there shall be a fourth or fifth—we forget which it is—asylum for the insane in Middlesex, the entire novel enterprise of building a *hospital*, properly so-called, should be attempted, just to settle the economic question whether an institution specially designed for curative purposes would not, as we have so often contended, do incomparably more to save the ratepayers' money than the most commodious caravansera devoted to the safe custody and accommodation until death of as large a lot of mixed lunatics as can be decently crowded within its walls.

CEREBRO-SPINAL FEVER.

FOR the last few years the annual death-rate of the Nara Gaol has been unusually heavy. Nearly three-fourths of the deaths recorded every year have occurred during the cold season—from October to February. Dr. P. H. Dadachanjee has forwarded a pamphlet on this subject, pointing out the probable nature of the disease causing the excessive mortality. After examining the history of the epidemic, and inquiring into the causes, of which prominence was given to season, overcrowding, bad water-supply, unhealthy locality, and the hardships of gaol life, he discusses the symptoms, course, and treatment of the disease, and comes to the conclusion that it was cerebro-spinal fever, which generally occurred in two forms. In the rarer and more acute, usually called the explosive form (meningite foudroyante), the onset was very sudden, and the patient from the very first complained of intense general prostration. Intense headache, vertigo, and irrepressible vomiting of bilious matter, contracted pupils, bloodshot eyes, temperature about normal or not above 100·5°, pulse 130 to 150, and delirium, ending in coma and death in from thirty-six to forty-eight hours, were the chief symptoms. In the milder and more frequent form the disease ran a slower course. Rigors followed by headache, flushed face, and suffused conjunctivæ, with photophobia, were observed. There was some vomiting, pyrexia up to 103° and 105°, and delirium. In some cases the disease progressed slowly towards defervescence, so that convalescence began about the tenth day, though headache and occipital pain remained for some time. Rheumatic pains in the lower limbs, petechiæ, and spasmodic twitchings were observed occasionally. The death-rate was about 70 per cent. The necropsy showed signs of inflammation of the membranes of the brain and cord. In the explosive form intense congestion of membranes only was detected. In other cases lasting more than five days, lymph, not uniformly distributed, was discovered filling up the sulci between the convolutions, but usually more marked about the anterior lobe and base of the brain. In the spinal cord considerable exudation occupied the subarachnoid space.

THE PASTEUR COMMISSION.

THE Commission of Inquiry into the system carried out by M. Pasteur to prevent the development of hydrophobia, which has been appointed by the British Government, has now commenced its investigation. The Commission consists of Sir H. Roscoe, M.P., who moved for the appointment of the Commission in the House of Commons, Sir James Paget, F.R.S., Dr. Lauder Brunton, F.R.S., Dr. Burdon Sanderson, F.R.S., Dr. Quain, F.R.S., Principal Veterinary Surgeon G. Fleming, of the Army Veterinary Department, and Mr. Victor Horsley, F.R.C.S., of the Brown Institute, the latter acting as secretary to the Commission. Sir H. Roscoe, Drs. Brunton and Sanderson, and Mr. Horsley are now in Paris, and before long the British public may look forward to the issue of a report which will enable them to appreciate the value which properly attaches to the processes adopted by M. Pasteur. The composition of the Commission renders it quite unnecessary to indicate the nature of the evidence which should be sought for; but we may say that, so far, no reports which have come under our notice have given sufficient evidence that their compilers have eliminated the many sources of error which have to be dealt with before any trustworthy opinion can be expressed as to the methods carried out in Paris. An exhaustive and searching inquiry tending to such elimination is, above all things, that which is wanted.

A GALLANT DEATH.

UNDER the above heading a relative of the late Surgeon Joseph Heath, who fell during the operations in Upper Burmah, writes some interesting particulars to the *Newcastle Daily Leader*. Dr. Joseph Heath was well known and intimately connected with the North of England, and one of his last official acts before he went to India, and while stationed at York, was to go to Newcastle to inspect one of the city ambulance corps. The following account is given in the article above mentioned as to the particulars of his death. The Saignain Fort, of which Dr. Joseph Heath was in medical charge, having been repeatedly threatened by Dacoits, a force was, on Saturday, Jan. 9th, sent from Mandalay in a couple of river steamers to their relief. On account, however, of the shallowness of the water, the steamers could only land troops at a spot above the fort, about a mile; hence, on their arrival, a council of war was held to discuss plans of operation, and at its conclusion, about 4 P.M., Captain Smyth, Lieut. Armstrong, and Dr. Heath were ordered to proceed to the vessels, the mission of the latter being to consult about hospital carriage for the column. When about midway on their journey, the three were pounced upon by a couple of mounted Dacoits, armed with spears, and accompanied by fifteen or twenty followers on foot, armed with guns and dahs (swords). The Dacoits fired, and Lieut. Armstrong and Dr. Heath were wounded. Dr. Heath, however, kept the assailants at bay with his revolver, and then, managing to mount Lieut. Armstrong on his back, carried

Digitized by Google

him along until he fell mortally struck by a second shot. Captain Smyth (the only one who escaped scot free) had then the unspeakable grief of being obliged to leave Dr. Heath's side, but managed to drag Lieut. Armstrong along until the troops, hearing the firing, came to his assistance, and the Dacoits fled. The writer further says: "That the three were allowed to leave the fort unattended when the surrounding country was known to be swarming with Dacoits is to us an impenetrable mystery, though on Dr. Heath, as a non-combatant officer, no blame for this can possibly rest." Poor Lieut. Armstrong, who was severely wounded in the face, succumbed in a few days. But one of his first acts after arriving at the hospital was to write on a scrap of paper in reference to Dr. Heath: "He was killed carrying me on his back."

MAMMARY FUNCTIONS OF THE SKIN IN LYING-IN WOMEN.

THE breast may be regarded as a highly specialised sebaceous gland, or, at least, as a highly specialised cutaneous gland. It may have developed out of the indefinite blastema of the epiblast, either directly or through the intermediary stage of a sebaceous gland. The distinction made by Dr. Creighton at the discussion of Dr. Champneys' paper on Tuesday last, at the Royal Medical and Chirurgical Society, will, in view of deeper embryological considerations, appear to be of not great importance. For it is plain that the glandular structures to which he referred must have originated from epiblastic germs, as the sebaceous, sweat, and mammary glands have also done. That a sebaceous gland is also a miniature breast must be regarded as theoretically proven from a chemical standpoint. Milk is a chemical compound in certain proportions of albumen, fat, and sugar, and analysis of sebaceous matter also yields fat and a small proportion of proteid and carbohydrate. Dr. Champneys' most careful and detailed description of the "axillary lumps" forms the result of an equally sedulous research, which, so far as is known, is unprecedented, and therefore original in the true sense of the word. The lumps that he described as situate in the axilla may for all practical purposes be regarded as mammæ. Their evolution follows step by step that of the mammary glands in parturient women, and there are some grounds for believing that they may be the seat of similar pathological affections. Further, Dr. John Williams bore testimony to the effect that, like the breast, the axillary lumps may show changes during menstruation.

ALCOHOL IN COLONIAL HOSPITALS.

THE great discussion on the use of alcohol in hospitals, for patients or officials, has extended to the colonies, and grows warmer at home. We have no objection to offer to this state of matters, so long as it is conceded that medical men are to be the judges of the necessity for it in patients. Other officials of hospitals must come to such terms as the hospital authorities and they can agree on. We should approve of the offer of an equivalent in money to all nurses, servants, &c. But whether a patient is to have alcohol must be decided by the same authority that decides whether he is to have quinine or bromide of potassium. While stoutly maintaining this point, we would urge on all hospital physicians and surgeons, as we have on private practitioners, that the responsibility of the prescription is great. If a man who has been abstemious comes into a hospital and finds that a great medical authority orders him a pint of stout a day or a few ounces of brandy, he is very apt to continue the use of the same when he leaves the hospital, and to think he has medical sanction for it. *A fortiori*, this would be the case of a man who was not abstemious. There is one other reason, and it is a very strong one—viz., that the attention of a large section of the public is strongly directed to this question, and that the existence of something like harmony of practice is desirable. A correspondent in the *New Zealand Times* gives the following as the expenditure per in-patient of the hospitals named. The information has been taken from the report of the Newcastle Board, the *United Kingdom Alliance News*, the Report of the Melbourne Hospital, and the return forwarded to the Wellington Hospital Committee: — Wellington Hospital, 14*s.* 10¾*d.*; St. George's Hospital, London, 4*s.* 8¼*d.*; Middlesex Hospital, London, 4*s.* 2*d.*; Melbourne Hospital, 3*s.* 8*d.*; Liverpool Southern Hospital, 3*s.* 4*d.*; University Hospital, London, 2*s.* 7¼*d.*; Queen's Hospital, Birmingham, 2*s.* 1*d.*; Southland Hospital, 1*s.* 6½*d.*; Edinburgh Hospital, 1*s.* 5*d.*; Westminster Hospital, London, 1*s.* 1*d.*; Manchester Infirmary, 9½*d.*; Leeds Hospital, 7½*d.* It will be gratifying to the English public to find that compared with New Zealand our English hospitals are extremely moderate. But the discrepancy between 4*s.* 8*d.* per head in St. George's Hospital and 1*s.* 1*d.* in the Westminster, or 7½*d.* in the Leeds Infirmary, is unseemly, and unlike the uniformity of science which we ook for now in therapeutics. We are sure that English physicians will treat this subject as a grave one, from both a moral and scientific point of view.

MICRO-ORGANISMS IN TYPHOID.

AFTER examining microscopically the bowel, mesenteric glands, spleen, liver, kidneys, lungs, heart, and brain in fourteen typhoid fever cases, Dr. Mirles of St. Petersburg concludes that the short bacilli of Eberth and Koch may, with great confidence, be accepted as always present in this disease, but that, in addition to this type of bacillus, colonies of three kinds must also be reckoned as characteristic of typhoid: 1. Small colonies in the deep layers of the intestine and in the walls of the capillaries of the heart muscle. 2. Medium-sized colonies of comma form. 3. Large ones of map-like shape, found especially in the mesenteric glands, the spleen, and in the substance of cerebral hemispheres. The author is inclined to agree with Klebs that some relation exists between the symptoms observed during life and the organs in which micro-organisms are found. In one case, for instance, where there had been violent and prolonged delirium, numbers of colonies of various sizes were seen in sections of the cerebral convolutions. He thinks also that the early development of cardiac weakness in uncomplicated cases of typhoid depends upon the existence of micro-organisms in the heart muscle, which are gathered in small colonies in the capillaries, and he suggests that it is much to be desired that careful observations should be made in typhoid of the exact condition of the pulse and of the sounds of the heart.

EPILEPTICS IN WORKHOUSES.

IT is much to be regretted that when the agitation about the sick in workhouses issued in Hardy's Act the retention of epileptics in workhouses was not altogether prohibited. Manifestly, they form a class of patients for whose safety the most effective provision ought to be made. The epileptic fit comes on too suddenly to admit of any precaution being taken by the sufferer for his own safety, and the insensibility which ensues is so profound that, as a recent deplorable occurrence at Falmouth unhappily shows only too forcibly, the victim may fall with his face on a fire and be actually burnt to death in that position, without power to move and probably without consciousness. To leave persons who are known to be subject to such seizures without protection is simply an act of barbarism. Another sort of protection is needed for those epileptics who, in the intervals of their fits, either just before or immediately after them, are liable to

Digitized by Google

paroxysms of cerebral excitement, alternating with depression, in which they are prone to commit, with or without consciousness, deeds of violence to themselves or others. Obviously, persons afflicted with this terrible disease in either of its forms are not fit inmates for a workhouse. Nor, indeed, are they fit for an asylum for the insane. It would be sound policy, in an economic not less than a medical sense, to provide special institutions for epileptics in every county. Unhappily there are more than enough to fill a large building, which should be constructed and furnished with a particular view to their comfort, and, in such cases as admit of remedy, cure. We venture to think that good would result from the incentive to further efforts to grapple with this malady which would be created by the erection of hospitals for the reception of epileptics alone.

THE VOLUNTEER MEDICAL STAFF CORPS AT THE EASTER MANŒUVRES.

AT both Dover and Portsmouth the members of this corps took a prominent part during the march on Friday and Saturday and at the field-day on Monday. The main body of the corps went to Dover, where, under the direction of Surgeon H. R. O. Cross, Grenadier Guards, excellent opportunities were afforded for work. On Friday a section of a field hospital was pitched, dressing and collecting stations were formed, and stretcher-bearer parties sent in search of the wounded, &c. On Saturday the number of sick, owing to the heat and the long march, was very large. The five ambulance waggons were full, and the surgery waggons had to be used for sick transport. The cases met with were cardiac excitement, sunstroke, epileptiform seizures, diarrhœa, kicks from horses, blows from passing vehicles, and the like. A mule with litters on Friday and cacolets on Saturday did excellent work in reaching the top of the almost perpendicular downs. On Monday but few of the troops fell out, though one or two curious accidents occurred; amongst others, the impaction of a small pebble in the front of a man's thigh was the most odd. Dr. Hearn, Principal Medical Officer of Queensland, Australia, who was attached to the bearer company during the Easter manœuvres, extracted the pebble, which was lying at a depth of two inches from the surface. Three bearer companies marched past at Dover, with a mule and cacolets, five ambulance waggons, five water-carts, and two surgery waggons. The military critics pronounced the appearance of the corps to be smart and workman-like and the march past to be good. The Portsmouth company earned unqualified praise from all onlookers, both for its appearance and efficiency.

CHOLERA IN THE VENETIAN PROVINCE.

ROVIGO, Padua, and other districts of the Venetian province have for the last two years been visited with cholera of the Asiatic type, but only sporadically. That the disease has never acquired any great diffusion or intensity is ascribed by the sanitary authorities there to the vigilance with which they have put in practice the treatment recommended as long ago as 1836 by Dr. Namias of Venice, and carried out with unvarying success by Dr. Tunisi of Padua, in his capacity of medical officer with the Italian forces in the Crimea and in Sicily (*vide* THE LANCET, Oct. 10th, 1885, p. 694). That treatment, summarised in a few brief instructions by the Cavaliere Bianchi, prefect of Venice, and distributed throughout all the towns of the province, is, in substance, the following. Cholera has two periods, that of preliminary diarrhœa and that of the graver symptoms, vomiting, cramp, extinction of voice, suppression of urine, &c. The former is always curable, the latter rarely so. The moment cholera has appeared in a community, every family should be provided with a phial containing from ten to fifteen grammes of laudanum, of which, on the slightest suspicion of diarrhœa, fifteen or twenty drops should be taken every half-hour in a teaspoonful of water. After the fourth or fifth dose the diarrhœa either disappears or is so diminished that the dose may be reduced and taken at longer intervals. For adults the laudanum taken from first to last may amount to from four to six grammes. Of 200 cases of choleraic diarrhœa treated promptly in this way, Dr. Tunisi, during the cholera epidemic at Messina in 1867, did not lose one; while the only deaths occurred among those who did not apply the treatment till the preliminary stage had passed and the graver symptoms had set in. His little book "Cura Specifica del Cholera" (Vicenza, 1885) was widely distributed throughout Spain last year, and proved highly serviceable in the visited localities.

PERNICIOUS EFFECTS OF ILLEGAL DRUG-SELLING.

THE evils of "doctors dispensing" have frequently been pointed out, and general practitioners are ridiculed and looked down upon by their continental brethren for "keeping pharmacies." The plan has certain advantages, however, as may be seen by a paper in a Russian medical journal (*Russkaya Meditsina*, No. 13) by Dr. A. A. Okinchits, showing that in the provinces, even in the largest towns, people are in the habit of getting their doctors' prescriptions made up at "pharmaceutical stores," which are kept and worked by utterly unqualified persons, who may have served their apprenticeship to grocers or coal merchants, and are wholly ignorant of the nature and properties of the medicines they both prepare and dispense. This kind of dispensing is of course illegal, but the transgressors are so cautious and cunning that it is a very difficult matter to catch them. They frequently keep the more active drugs—that is, those which none but licensed pharmacists have the right to sell—labelled as totally different and innocuous substances, and so any police official who may come to inspect is led to suppose all is right; probably, too, a judicious "tip" would quickly remove his suspicions, even if aroused. Occasionally, however, some mistake occurs which cannot be entirely hushed up. A doctor having prescribed some sulphate of atropine for a patient to use as eye drops, and the prescription having been made up at one of these "pharmaceutical stores," kept by an unauthorised person, a child saw the lotion and drank it, but was none the worse, the fact being that the sham pharmacist, from motives either of knavery or ignorance, had sent plain water—as it happened, a very providential error. These illegal stores keep all the quacks and "witches," who practise on the credulity of the peasantry supplied with the powerful mercurial and other preparations they are accustomed to employ, so that they act as disseminators of poison to an incalculable extent, and it is time that some stringent methods for their suppression were resorted to.

THE PERIL AND PLAGUE OF NARCOTICS.

SCARCELY a week passes without some sad proof of the folly of a reckless or insufficiently careful use of narcotics. It is almost to be regretted that so many agents capable of producing mimic, or poisoned, sleep are known to the profession and to the public. It is now the exception, instead of the rule, to find a man or woman of middle age who is not more or less addicted to the abuse of morphia, chloral, bromide of potassium, or some one of the many sleep-inducers or pain-relievers which the nineteenth century has distinguished itself by evolving for the care and comfort of our less enduring and increasingly sensitive and excitable humanity. It is nothing to the purpose that the deleterious effects of these potent drugs, when taken habitually, even in

Digitized by Google

small quantities, have been again and again exposed. Practitioners have, as we do not scruple to insist in and out of season, much responsibility for the growing fashion of taking narcotics or anodynes by mouth or hypodermically. It is so pleasantly facile to prescribe a remedy which is sure to give present relief, whatever may happen in the future; and those who have learnt to purchase unconsciousness or ease at what seems to be a very small price are only too ready to renew the experience when any fresh cause of sleeplessness or pain arises. Sooner or later some strong measure will need to be taken with the view of arresting this really serious "habit" of taking sedatives, which is extending its influence and gaining strength year by year. Meanwhile, we do very earnestly counsel our readers to refrain from having recourse to these drugs themselves, and to use their authority with patients in condemnation of a demoralising and disastrous practice. The victims of the abuse must not simply be counted by those who die of it, but by those who are left to drag out miserable lives, the victims of "cravings" and nameless and numberless sufferings, which morphia, chloral, bromide—now cocaine—and a host of insidious poisons, are the active agents in producing.

TESTIMONIALS.

WE all know that there are testimonials and testimonials. There is the routine formula, which is apt to be given almost promiscuously to all applicants, and which comes to be appraised at its true value. In a recent discussion at Southampton it was proposed to alter a rule which prohibits the appointment of physicians and surgeons to the Royal South Hants Infirmary unless they have resided three years in the town. The motion was carried by a small majority, but not by the necessary majority of two-thirds. In the course of the discussion and in opposing the motion, Dr. Lake spoke very slightingly of testimonials. "Speaking of the worthlessness of testimonials," he said: "A man of the reputation of Sir William Fergusson would sign anything—his own death warrant. He had been known to sign testimonials which students had written themselves." The report is from the *Hampshire Advertiser*. We cannot but believe that Dr. Lake is in error in this particular statement. But there is undoubtedly room for much more care and discrimination in giving testimonials, which are often given to persons on very inadequate knowledge of character and career.

THE NIGUA IN MEXICO.

SOME researches by Señor Donaciano Cano y Alcacio on the Nigua are noticed in the April number of the Mexican journal *El Observador Médico*. This insect, which is popularly known under various names (chigoe, chique, sikka, tunga, pique, &c., and scientifically as Ryncoprion penetrans and Pulex penetrans), has been referred by different entomologists to the Aptera, Hemiptera, and Diptera, according to the characters of which each took special note. Señor Cano believes that it is the male insect only which by its growth under the skin gives rise to the troublesome lesions which are due to the nigua, and which are sometimes followed by phagedænic ulcer, gangrene, or tetanus. The prophylactic measures consist in cleanliness, seeing to one's boots, examining the feet at night, and avoiding localities known to be infested by the insect. For poor people who cannot get proper coverings for their feet, and who may be obliged to frequent the nigua's habitats, he advises a turpentine application to the feet. The only treatment is to remove the animal. For this a large blunted needle is required. Care must be taken not to rupture the abdomen, which is the largest and most superficial portion of the body. This is sometimes partially adherent to the skin, and if so a little dissection must be practised, as in the case of wens. Often, however, either by pressure or with a little manipulation with the blunt needle, the insect can be very easily dislodged. At the commencement of the operation a dark liquid is generally seen spirting out like a fine spray from the animal. This is due to the irritation causing it to act on the defensive. The liquid may probably be of a fæcal nature. Where purulent collections exist, the cavities should be carefully and frequently washed out with antiseptic and insecticide solutions. At the Mexico Military Hospital a 1 per 1000 sublimate solution is first employed, and afterwards strong solutions of boracic acid. When there is gangrene Señor Montes de Oca wraps the part up in calcined gypsum, which arrests the offensive odour, limits the gangrene, and prevents the absorption of septic matters by the healthy tissues. The natives employ tobacco applications to the sores after getting rid of the insect, but this is not in any way necessary, and is liable to cause considerable inconvenience.

RISKS OF INTERMITTENT WATER-SUPPLY.

THE dangers of the intermittent system of water-supply to houses is well illustrated by an event which recently happened in Marylebone, and of which Mr. Wynter Blyth gives account in his last report. When the water was turned off by the water company's officer, a vacuum was created in the water main, and a quantity of coal gas which had escaped from a leak in the gas pipe in the ground was sucked in; when the water was again turned on, coal gas was delivered into the house with the water. In houses where the ground becomes saturated with filth by defective drainage, it is probably of no uncommon occurrence for the water to be polluted in the mains by filth of this nature. Coal gas is easily detected, but it would be quite possible for more dangerous gases to enter the main without recognition. The risk is most easily avoided by the adoption of the constant system of supply, but even constant service must be occasionally interrupted when necessity arises for the repair of water mains. The provision of a stop-cock to every house would go far to obviate this danger.

THE HISTORY OF THE GENEVA CONVENTION.

AT its first meeting on April 19th, the President of the Third Congress of the Italian Surgical Association conferred on the senator, Professor Palasciano, on Dr. G. Mazzoni, assistant in clinical surgery, and on Dr. Di Fede, of the Military Hospital in Rome, the prizes for the memoirs presented by them on this subject, the competition for which was announced at a meeting of the Association in April, 1883. These memoirs are designed to revindicate for Italy the honour of having been the first to suggest the humanitarian movement in aid of the wounded in war, a movement which culminated in the international treaty known as the Geneva Convention. It was the deplorable condition of the wounded in the Crimean and Italian campaigns that impelled Palasciano to propose at a meeting of the Accademia Pontaniana at Naples on April 28th, 1861, that an international treaty should be concluded for neutralising the sick and wounded in war, and for augmenting, without limit, the sanitary *personnel*. In June of the same year Arrault recommended, instead, that the sanitary *personnel* only should be neutralised; and in 1862, Henri Dunant of Geneva, in his attractive book, "Un Souvenir de Solferino," proposed the creation of squadrons of hospital volunteers to reinforce the official sanitary staff. The Geneva Society of Public Utility started a conference apparently with the object of advocating the scheme of Dunant, but really with the result of making its own the humanitarian project of Palasciano. Hence it is that the Geneva Convention, in

Digitized by Google

consequence of the aforesaid conference and of a treaty negotiated through an International Congress, has come to be popularly considered as a Swiss creation. Round the name of Dunant has gathered a tradition, or rather legend, fostered by his compatriots, who have not failed to give special prominence to his work and to the Geneva Convention, whilst relegating to silence or insignificance the really initiatory part borne by the Italian surgeon. It is the merit of the above-mentioned memoirs, particularly those of Mazzoni and Di Fede, to have established by incontestable proofs the priority of Palasciano in the great international organisation on behalf of the sick and wounded soldier; and the publication of the two latter—which, it seems, supplement and reinforce each other—will, it is confidently hoped, bring the professional mind of Europe to the same conclusion with that of Italy, that it is to Italian initiation that humanity owes the inspiration and origin of the Geneva Convention.

CHOLERA IN EUROPE.

THE outbreak of cholera in Brindisi does not appear to be extending, but, on the contrary, the latest news is to the effect that it is rapidly diminishing, and that but few deaths have occurred from it. The only news of cholera during the past week has been that from Brindisi, and intelligence from other parts of Italy is to the effect that, with the exception of the northern portion of the Adriatic, the peninsula is quite free from the disease. In Naples special precautions are being taken, by way of cleansing and otherwise, to prevent any recurrence of cholera, and although some complaints are made as to the method of distribution of the new water-supply, yet great confidence is expressed that this excellent water offers a safeguard not heretofore experienced by the Neapolitans. We could, however, wish that cleanliness in the matter of drainage and sewerage were possible under existing circumstances, but so long as the present system continues the narrow thoroughfares in the lowest parts of the city must be offensive, and the bay in the vicinity of the shore must remain little better than a great offensive cesspool. No effort should be spared to secure such a system of drainage and of sewage disposal as will free Naples from these grave sources of nuisance and danger to health. The inhabitants of Sicily, forgetting their protests of last year, are again calling for protection by means of a rigid quarantine system, which can only isolate them from the mainland.

WHAT DOCTORS PRESCRIBE.

THE subscribers to the *Chemist and Druggist* have been asked to send to the editor 10,000 prescriptions. And one of the members of the editorial staff of that journal has set himself the task of arranging this motley mass of statistics into such a shape that certain, in a measure, interesting facts are brought prominently forward. According to this somewhat haphazard, and by no means, we should think, representative mode of collecting physicians' prescriptions, the conclusion may be drawn that the inhabitants of this sometime favoured isle suffer largely from diseases of the imagination. But the imagination is a function of the whole or some part of the nervous system. Hence a further deduction. This conclusion may not be a just inference, but the premisses on which it rests are these: Spirits of chloroform, sal volatile, glycerine, and syrup of orange-peel take high places, as drugs most frequently prescribed; to these we may add bromide of potassium, which ranks second only to chloroform. Most of these may be grouped under the heading "placeboes." Wine of ipecacuanha, sulphate of quinine, bicarbonate of soda, carbonate of ammonia, liquor ammoniæ acetatis, potassii bicarbonatis, and spiritûs ætheris nitrosi are the other members of the group of twelve drugs most frequently ordered. Several of these minister to the disorders of the respiratory tract, and the time of the year may have some influence on their use. But, as we said at the beginning, the information cannot be regarded as representative. If the statistics of some hospitals and dispensaries were taken, we believe that bicarbonate of soda, rhubarb, and gentian would exceed the other drugs in respect of frequency of prescription. Further, spirit of chloroform and syrup of orange-peel are mainly used as adjuncts.

A DEGREE-GIVING MEDICAL FACULTY UNCONNECTED WITH A UNIVERSITY.

IT has been assumed by the opponents of the scheme for constituting the combined Colleges of Physicians and Surgeons a medical faculty, with power to confer medical degrees, that such a faculty, standing by itself and unconnected with a more or less complete university, would be an anomaly, and that there is no precedent, on this side of the Atlantic at least, for the existence of a body having power to confer medical degrees apart from a university. This, however, is a mistake. One of the most flourishing medical schools in Europe precisely exemplifies this state of things. We refer to that of St. Petersburg, the title of which is the Imperial Military Medical Academy, and which is regulated by the Ministry of War, and has no connexion with the University of St. Petersburg, which, though very complete in other respects, entirely lacks a medical faculty. It must not be supposed that the Military Medical Academy merely supplies the place which the Netley School does in this country. It is complete in itself, and, moreover, has the power of conferring the titles of "Vrach" or Licensed Medical Practitioner and Doctor of Medicine. As in the medical faculties of the other Russian universities—Moscow, Kazan, Kharkoff, the St. Vladimir in Kieff, Warsaw, Dorpat, and the Alexander in Helsingfors,—all students have to pass the examination for the title of "Vrach"; and only those who do this with distinction are permitted, after a further period of study, to become a candidate for the Doctorate, for which an original dissertation has to be presented, implying a good deal of patient research. The points proved have to be publicly defended by the candidate against all comers. Several of these dissertations, which are all printed in the Russian language, are now before us. They state on the title-page that they are "for the degree of Doctor of Medicine," and they bear the certificate of approval of the "Conference of the Imperial Medical Academy," being signed by the "scientific secretary," no reference whatever being made to any university. It may be added that the entrance examination for admission to medical study or to any of the university faculties implies a considerable acquaintance with classics, mathematics, and modern languages. It is held at the gymnasia or public schools, and embraces the subjects taught in the final or eighth class, which is probably superior to the majority of English sixth forms.

DR. OTIS ON HEALTH-RESORTS.

DR. OTIS, of Boston, has lately read before the Suffolk District Medical Society an important paper on Health-resorts. He says at the outset that he is not a partisan of any special place as a universal elysium for those afflicted with lung troubles; each individual case should be fully studied and sent to a place which seems to meet its own special requirements. He is convinced that a long continuous residence in a climate which has been found to suit the case is what gives the best results. "It takes a long time to become acclimated if the change is at all radical," and after that comes the benefit. Dr. Otis has "almost come to the conclusion that no physician has any right to advise a

Digitized by Google

patient to this place or that unless he has first visited it himself and thoroughly investigated its advantages and defects." The southern resorts in the United States may be divided into those of the coast, interior, and mountains. Of the coast resorts, those in Florida are generally selected, and it is a matter of opinion whether the Atlantic or Gulf of Mexico shore is the more favourable. One fact he lays considerable stress upon is that it is exceedingly difficult to get good food in the south. In the discussion which followed, several speakers expressed their entire approval of Dr. Otis's warning as to the great importance of being thoroughly acquainted with a locality before advising the removal to it of a particular patient.

THE HAIR ROOTS AS INDICATORS OF BODILY OR MENTAL DISEASE.

DR. J. POHL-PINCUS, of Berlin, has recently, in a *brochure* entitled "Polarised Light as a means of recognising Irritable Conditions of the Nerves of the Scalp," announced that by an examination of the hair roots by polarised light peculiar changes may be observed whenever the patient suffers from physical irritation or mental excitement. This statement is the result of investigations which have now been going on for twenty-five years, and the later observations in the course of the research have uniformly confirmed those made earlier. The hair bulbs are divided into three groups, as follows:—Group A: If, in healthy conditions of the body and mind, the hairs that fall out daily are examined microscopically by polarised light, the enlarged bulbous end of the root will show a white contour, and a yellowish or brownish-red centre. Group B: In all irritable conditions of moderate grade, all painful conditions of any organ, also in emotional disturbances of moderate grade, without any apparent bodily disease, the bulbous end of the hair root increases in length and breadth (in proportion to the irritation), the central part appears under polarised light of a violet, blue, or bluish-green colour, separated from the white contour by bands of yellow and red. Group C: In higher grades of bodily disease or mental disturbance, the bulb becomes still larger, and the bluish centre changes to green, yellow, or orange. A few hairs of the B and C types are found in normal conditions, especially in those more advanced in life. Dr. Pincus gives thirty-one cases showing the effects of painful disease, but more especially of depressing emotions, upon the appearance of the hair root. The conclusion to be derived from these researches is that bodily disease or mental excitement causes circulatory disturbances, and in consequence a change in the normal nutrition and pigmentation of the hair. This is only in accordance with previous observation, and the chief merit of Dr. Pincus's plan lies in his obtaining a means by which very slight and temporary changes in tissue growth can be detected and approximately measured.

FOREIGN MEDICAL PROFESSORSHIPS.

DR. A. VOGEL, Professor of Special Pathology at Dorpat, is resigning on account of his health; he will, however, be able to continue to practise privately. Dr. F. Penzoldt, Extraordinary Professor in Erlangen, has been appointed to the Professorship of Pharmacology in the same university. It is stated that Professor Kussmaul, of Strasburg, contemplates resigning his chair and settling in Heidelburg. Professor Späth, who holds one of the obstetric chairs in Vienna, has applied for his pension.

A TELEGRAM from the Viceroy of India, dated April 27th, states that cholera has broken out amongst the troops at present engaged in Burmah. Fourteen deaths have already occurred, but all possible precautions are being taken to prevent the disease from spreading.

AT the Conversazione for which invitations have been issued by the President and Council of the Medical Society of London on Monday next, visitors will have the opportunity of inspecting the unrivalled collection of works by the great water-colour masters, which have been lent, by the kindness of Mr. James Orrock, for the occasion. Besides these there will be on view specimens from their galleries which have been sent for the occasion by the generosity of Messrs. Doulton. Various forms of electric lighting applicable to medical work will also be on view, and the proceedings are to be enlivened by the band of the Royal Artillery.

PROFESSOR V. FRISCH, of Vienna, who had recently returned from a visit to Paris, reported the results of his investigation into M. Pasteur's inoculation method to the Society of Physicians at Vienna. He said that M. Pasteur had unreservedly supplied him with every information, but owing to the prolonged period of incubation which often characterises hydrophobia, he held it to be premature at present to report definitely upon the utility of the practice. He also considered that the results should be controlled by experiments upon animals.

WE hear that Dr. Rolph Leslie, of the University of Toronto, Canada, and St. Thomas's Hospital, London, has been decorated with the Order of Leopold by the King of the Belgians for his services on the Upper Congo.

THE Council of University College, Cardiff, has presented a strongly supported memorial to the Lord President of the Council urging the desirability of establishing a medical faculty at Cardiff in connexion with the University College.

THE following members of Parliament are showing a great interest in the Charities Rating Exemption Bill:—Sir Julian Goldsmid, Sir Robt. Fowler, Messrs. Ernest Baggally, H. W. Lawson, O. V. Morgan, and Sir Algernon Borthwick.

La Gazzetta degli Ospitale (April 21st) reports a communication by Dr. Sacchi to the Medical Academy of Genoa on Tracheotomy in Croup. Of five children on whom he performed the operation, two survived.

PROFESSOR CORFIELD will commence his course of lectures on Hygiene and Public Health at University College by an introductory lecture on Tuesday, May 4th, at 4 P.M.

A RECENT law enacted in Georgia requires all preparations of morphine to be dispensed in scarlet paper with a scarlet label having the name of the contents in white letters.

THE eighth National Medical Congress of Italy, which was to have met from the 2nd to the 6th of May at Palermo, has been adjourned on account of quarantine.

THE death is announced of Dr. Thaon, of Nice, well known for his work on Tuberculosis. He was forty years of age.

EIGHTEEN persons were, on the 27th of March, at Leicester, fined 10*s.* each for neglecting to have their children vaccinated. For the same offence there are now in the same town about 14,000 summonses to issue, besides many thousand notices.

THE work of alteration at the Leeds Fever Hospital, commenced in August last, is now completed. Accommodation is provided for over 100 patients, the average number of inmates in the old premises having been for the first few years about 20.

INDIAN HEALTH STATISTICS.

No. I.

THE twenty-first Annual Report of the Sanitary Commissioner with the Government of India for the year 1884 gives the usual information regarding the health of the European and native armies, the gaols, and the civil population, with a statement of the expenditure on sanitary works, military and civil, during the year. In one respect, however, an important change has been made: the papers on scientific subjects, which formerly appeared as appendices to the report, have been omitted, as it is intended to publish them in future in a separate volume under the title of "Scientific Memoirs by Medical Officers of the Army of India." It is hoped that the establishment of such an annual volume will be appreciated by the profession, and will prove a stimulus to medical officers to carry out original investigations on subjects connected with their special work.

During the year 1884 the average strength of the European troops serving in India was 54,996. The admissions into hospital were in the ratio of 1513 per 1000, the deaths of 12·56, the invaliding to England of 31·74, and the constantly non-effective from sickness of 67·99. With the exception of the invaliding, these ratios are all higher than those of the preceding year, but the death-rate was still much below the average. The following table shows the incidence of sickness and mortality in each of the three Presidencies:—

	Average strength.	Annual ratio per 1000 of strength.			
		Admitted into hospital.	Died in India.	Invalided to England.	Mean daily sick.
Bengal	33,486	1662	11·68	31·84	70·5
Madras	10,735	1109	8·53	31·82	57·6
Bombay ...	10,725	1455	19·39	31·36	65·5

In all the Presidencies there was an increase in the rate of admissions into hospital. In Madras there was a marked reduction in the deaths, which amounted only to 8·53 per 1000, or little more than 1 per 1000 above the average of infantry serving in the United Kingdom; there was a slight increase in the mortality in Bengal, and a very marked one in Bombay. The latter, however, was due to the high death-rate among the troops serving in Southern Afghanistan, averaging 1441 men, for if they are deducted the deaths in the remainder of the Bombay European Force were only in the ratio of 11·74 per 1000, or slightly above that of Bengal. The invaliding from Bombay was considerably less than in 1883. In Bengal and Bombay there was a marked increase, and in Madras a slight decrease in the mean daily sick. The increase in the admissions in all the Presidencies was chiefly in the class of fevers, but in Bombay also in venereal diseases, and of the latter there was likewise an increase, though much less marked, in Madras. The great excess of deaths in Bombay was caused by cholera, and there was an increase also in those by enteric fever and by violence; the decrease in the mortality of Madras was chiefly in enteric fever. The ratio of deaths by it during the year was 3·31 in Bengal, 1·07 in Madras, and 2·05 in Bombay. In Bengal the disease proved most fatal at Morar, Agra, Gwalior fortress, Dinapore, Lucknow, Meerut, Mooltan, Sialkot, and Rawalpindi; in the Bombay Command at Quetta, and in Madras at Secunderabad. At Bangalore 60 cases were returned, but with only one death—a circumstance which throws considerable doubt on the accuracy of the diagnosis of the cases. September and April were the months in which it was most prevalent, and January and February those in which the smallest number of cases occurred. The mortality was much greater, in proportion to the numbers serving, among the men under twenty-five than above that age, and during the first two years of service in India. It is worthy of note, however, that in 1884 the death-rate from enteric fever in the newly arrived regiments (during their first year of Indian service) was lower than in the army generally, in the proportion of 2·33 to 2·74 per 1000. It is stated that in the great majority of cases "no clue whatever can be found to the causation of the disease in any local insanitary conditions." At Sitapur the medical officer attributed it to the unsatisfactory state of the latrines, and this opinion appears to be confirmed by the fact that "after the proper glazed earthenware pans were supplied, the latrines became perfectly free from stench—in fact, from any smell; the health of the troops improved; there were no more admissions for enteric fever; and a very considerable decrease in the number of admissions for diseases of the digestive system."

Cholera did not prevail to any great extent among the European troops in 1884, the admissions having amounted only to 2·7 and the deaths to 1·95 per 1000 of the strength; the mortality in the three Presidencies respectively was—in Bengal 1·34 (or slightly above the ratio of the preceding year), in Madras 0·95, and in Bombay 4·85 per 1000 of the strength, the last being greatly in excess of the average of previous years. But this excess in the Bombay force occurred chiefly among the troops employed in Southern Afghanistan, for if they are omitted, the death-rate amounts only to 1·40 per 1000, or very little above that of Bengal. In a force of 1088 men marching in Southern Afghanistan, forty-nine cases with thirty-nine deaths were reported in the month of December, which gives a ratio of 45·04 and 35·84 per 1000 of the strength. The report does not furnish any details of this outbreak, or of the measures adopted to check it. In Bengal, Meerut was the station which suffered most, the cases having been twenty-nine with thirteen deaths in a force of 1682 men; Allahabad and Dinapore also had an undue proportion of cases.

Venereal diseases continue to be a source of much inefficiency in the army in India, the admissions having amounted in 1884 to 294 per 1000, considerably in excess of the average of previous years. The increase was shown in all the Presidencies, but was most marked in Bombay.

The most prevalent causes of invaliding from India are anæmia and debility, usually a consequence of fever, hepatic affections, phthisis, heart disease, and rheumatism.

The influence of age on the mortality of the European troops in India is shown to be as follows:—Death-rate under twenty-five, 11·06; from twenty-five to twenty-nine, 9·99; from thirty to thirty-four, 9·71; and thirty-five and upwards, 13·66. The excess in the younger ages is due entirely to two diseases—enteric fever and cholera; omitting these the ratios would run—6·45, 8·16, 9·58, and 12·67 per 1000 living at each age.

The death-rate of the officers in 1884 was 9·17 per 1000, or 3 per 1000 lower than in the preceding year. Among those of the British army it was 10·30, and of the Indian army 8·11, the difference being chiefly in deaths by accident and violence. That of the women was 17·50, being lower than in any year of the preceding decade; 10 per cent. of the deaths were caused by childbirth and abortion.

The average strength of the native army was 114,827; the admissions into hospital during the year were in the ratio of 1042, the deaths from all causes 12·22, the discharges by invaliding 20·62, and the mean daily sick 33·2 per 1000. The relative health of the native armies of the three Presidencies was as follows:—

	Ratio per 1000 of strength.		
	Admissions.	Total deaths.	Daily sick.
Bengal	1193	12·56	35·5
Madras	836	11·82	30·9
Bombay	1153	14·35	36·1

In all three Presidencies there was an increase in the admissions and mean daily sick, but a decrease in the deaths compared with the results for the preceding year. The excess of admissions in all was chiefly caused by the prevalence of fevers; in Bengal there was also an increase in dysentery, and in Bombay in respiratory diseases. Enteric fever furnished only 18 cases and 11 deaths in the whole army. There was a marked exemption from cholera, of which only 135 cases and 82 deaths occurred, being in the ratio of 1·7 and 0·71 per 1000 of the strength; half of the deaths and rather more than half of the cases occurred in the Madras force. There were 46 cases and 27 deaths at Secunderabad, and 16 with 4 deaths at Madras; in Bengal the greatest number of cases occurred at Dinapore, where there were 12, of which 5 died. The most fatal class of diseases in all the Presidencies is that of the respiratory system, which in Bombay gave rise to one-third of the total deaths.

The summary of the sanitary sheets of native troops

Digitized by Google

shows that a considerable amount of overcrowding exists, and that there is still much to be done in improving ventilation, water-supply, diet, and conservancy before the state of the army can be considered satisfactory.

NEGRO MORTALITY IN THE UNITED STATES.

IN Volume XI of the Report upon the last census in the United States, dealing with mortality and vital statistics, are to be found some interesting statistics bearing upon the mortality among the coloured population, mainly consisting of negroes. In the southern portion of the States the rate of mortality of the coloured population, amounting to nearly 7,000,000, is reported to have been equal to 17·28 per 1000; whereas the recorded deaths among the more than 43,000,000 of the white population of the States did not exceed 14·74 per 1000. There can be no doubt, and indeed it is freely and fully admitted by the census authorities, that these reported rates very considerably understate the true rates of mortality among the population of the United States, probably to the extent of nearly a third. It is further admitted that the deficiencies in the enumerator's returns of deaths are "greater for the coloured than for the white population," so that these figures do not fully indicate the excess of mortality among the negroes, although they show in equal numbers living 117 deaths among the coloured population to 100 among the whites. Taking twelve Southern States that contain the largest proportions of coloured population, it appears that the recorded death-rate was 14·04 among about 8,000,000 of white population, and 17·22 among rather more than 5,000,000 of coloured population; these figures give 122 deaths among the coloured population to 100 in an equal number of the white population. That even these figures very considerably understate the real excess of mortality among the coloured population may safely be inferred from the following facts. There are thirty-one cities in the United States in which civil registration of deaths is more or less completely affected, and in six of these so-called registration cities—namely, in Baltimore, New Orleans, Washington, Louisville, Richmond, and Charlestown—a very considerable coloured population was enumerated. The population of these six cities at the last census amounted to 933,038 persons, of whom 697,157 were white and 235,881 coloured. The facts given in a table in the Census Report show that the recorded death-rate in the census year 1879-80 was equal to 21·41 among the white and to 36·62 among the coloured population of those six cities. Thus the mortality among the coloured population was in the proportion of no less than 171 to 100 in an equal number of the white population. It is acknowledged that even in these so-called registration cities the record of deaths is by no means complete, and there is good cause to assume that the registration deficiency is greater among the coloured than the white population, from which it follows that even the 71 per cent. excess of mortality in the coloured population understates the real excess of mortality among the negroes residing in six of the largest cities of the southern States of America. It should be stated that the general mortality in these southern cities considerably exceeds that which prevails among the cities in the northern States, the result propably of climatic influence; but, sanitary condition (in the broadest sense of that term) being equal, it would be natural to expect that the effect of the southern climate would be more fatal to the white than to the coloured population. The above figures afford conclusive evidence of the defective sanitary condition of the negro population, especially in the southern cities. One of the main causes of the excess of mortality among the coloured population is stated to be the excessive rate of infant mortality that prevails therein. It is admitted that the facts available for calculating infant mortality in the United States are only less defective than are those from which the death-rates at all ages have to be calculated, but as regards the numbers of births and of deaths under one year of age the census report says, "The defects and errors tend to neutralise each other, since the greater the deficiency in the reports of deaths of infants, the greater also is the deficiency in the reports of births." A table in the report gives the rate of infant mortality measured by the proportion of deaths under one year to recorded births in certain sub-divisions of the United States, called Grand Groups. In six of these Grand Groups the relative proportions of infant mortality in the white and coloured populations are separately shown. It appears that the mean proportion of infant mortality in these six Grand Groups was as 188 in the coloured population to 100 in the white population. This certainly shows a still larger excess of mortality among the coloured population than any previous test, but as the proportion of excess in the coloured mortality in the thirty-one registration cities, at all ages, was 71 per cent., it is evident that the excess at other ages is not much less than that of the mortality in infancy. As regards the causation of the excess of mortality among the coloured population, it may well be imagined that, defective as is the mere record of the numbers of deaths in the United States, the information bearing upon the causes of death is still more untrustworthy. The tables given in the Census Report, moreover, bearing upon this branch of the subject, only give the relative proportions of deaths from the different causes to the total deaths among the white and coloured populations; this comparison does not give sufficiently approximate indications of the rates of mortality from these diseases in the two populations to afford the means for trustworthy deductions. It may be noted, however, that the proportional numbers of deaths referred to scarlet fever, diphtheria, enteric fever, diarrhœal diseases, cancer and tumours, diseases of the nervous system, diseases of the circulatory system, and diseases of the urinary system are considerably larger in the white than in the coloured population; while, on the other hand, the proportional numbers of deaths from measles, malarial fever, venereal diseases, scrofula and tabes, consumption, pneumonia, affections connected with pregnancy, and accidents and injuries were considerably larger in the coloured than in the white population. It appears, therefore, as Dr. Billings states in his report, "that the coloured race is peculiarly liable to certain forms of disease, and is less liable than the white race to certain other forms of disease; but when we take into account the effects of climate and soil moisture, the great majority of the coloured population being in the south, it is hard to say whether the negro in this region under the same circumstances as the white would be shorter lived or not." Dr. Billings asserts that "in the rural districts the mortality of the negro is not excessive"—meaning, presumably, in comparison with the mortality of the white; but it must be borne in mind that he has admitted that the mortality statistics of rural districts are more defective than those of urban districts, and that the defect of the records is still greater among the coloured than among the white population. It may be fairly doubted, therefore, whether trustworthy means exist for testing the real excess of negro mortality in the rural districts. At the same time, it may readily be believed that it is in cities and towns where the negro is "brought into close contact with the evils and vices of civilisation that he dies so rapidly." Dr. Billings acknowledges the importance of the questions: "How far the excessive mortality in the coloured population is due directly to race characteristics—that is, to less vital force or capacity to resist disease and death; and how far it is due to the fact that the great mass of the coloured population is poor and ignorant, lives in the midst of unhealthy surroundings in the dampest and dirtiest parts of cities, has poor food, and is in other respects unusually exposed to well-recognised causes of disease." It is pointed out that the statistics of the negro population are in the main the statistics of a poor working-class population, and it is suggested that, if it were possible to show separately the mortality statistics of a similarly poor and ignorant class of the white population—the tenement-house population of the northern cities,—they would probably show an excess nearly equal to that in the coloured population. Whether this would prove to be the case or not, the marked excess in the mortality of the negro population is beyond question, and points conclusively to the unfavourable sanitary conditions under which this population lives, especially in the larger cities of the Southern States.

DEATH OF THE NORTH TYNE CENTENARIAN.—Mr. Joseph Saint, the North Tyne centenarian—mentioned last week in the letter of our Newcastle-on-Tyne correspondent—died on Tuesday at Chollerton, in his 103rd year; he had been confined to his bed only a fortnight.

THE EXHIBITION OF THE ROYAL ACADEMY OF ARTS.

THERE are very nearly 2000 works of art collected within the walls of the Academy this year, and one cannot refrain from the thought that in this time of depression there must necessarily be a large percentage of these which is destined to remain unsold. To have one's picture exhibited is to pass, but to dispose of it for a good round sum is to take honours, and at the present time the honours list must necessarily be small.

It would be out of our scope, even if the short survey which we have made permitted of it, to attempt any detailed criticism of the works exhibited. Our business is really confined to directing attention to such as, from one cause or another, are likely to prove of especial interest to the medical profession. But we cannot shut our eyes to the fact that there is a collection of great, perhaps unusual, worth to be seen this year.

The bronze statue which Sir F. Leighton exhibits, termed "The Sluggard," is a work of extreme originality and interest. A young male figure, of beautiful proportions, is indulging in that stretching of the limbs which is so recreative after fatigue, and the attitude assumed gives the artist ample scope for displaying his knowledge of human anatomy. The right lower extremity is firmly, perhaps a trifle too stiffly, planted on the ground, and forms, as it were, a pedestal, allowing free and graceful play to the muscles of the other limbs. The work is very remarkable, and will deserve most careful study.

In portraits of members of our profession the exhibition is unusually prolific. An admirable likeness of Dr. Wilks, by Miss Emily Merrick, meets us in the first room, where also is one of Mr. T. A. Rogers. Mr. Ouless has been busy amongst us this year. He sends the portrait of Sir Henry Pitman, which was unveiled at the last Comitia of the Royal College of Physicians; and in the third gallery, one of Dr. Burdon Sanderson, presented by his personal and scientific friends. This is a good study of a fine head, not perhaps everything that could be wished as a mere likeness, but an admirably suggestive portrait, which is better than a startling likeness. In Gallery No. 11 Professor Humphry appears—another excellent portrait, which has been painted by Mr. Ouless. We are not so much pleased with the portrait of Dr. Hermann Weber, by Mr. Burgess; that admirable artist has not, we think, been quite so successful in picturing the power as he has in rendering the amiability of his sitter's face. Surgeon-General Longmore, C.B., lecturing to a class on some ophthalmic subject, is a pleasant portrait, by Mr. George Reid. There are also portraits of Mr. Clinton Dent, by Mr. Wirgman; of Dr. Frankish, by Mr. Dampier May, the latter well painted and true; nor must we forget that of Brigade-Surgeon Wallace, by Mr. Hacker. In the department of sculpture we find a marble bust of the late Mr. W. C. Worthington, a well-known provincial practitioner, by Mr. Roscoe Mullins; and a large statue of the late Sir Erasmus Wilson, which is to be executed in bronze and erected in front of the Sea-bathing Infirmary at Margate. In the same department is a marble bust of Sir James Paget by Mr. Boehm, and a plaster cast of the statue of John Hunter presented by the Queen to Oxford University Museum; this is by Mr. Richard Pinker.

The members of our profession who from time to time out of their scanty leisure have contributed as amateurs to the Exhibition are this year not represented. But we note with much pleasure a charming bit of still life—a vase containing daffodils against a background of tapestry—the work of Miss Edith Brinton. Those who remember the late Dr. Brinton, the brilliant physician whose early death so many friends have mourned, will see with interest that the artistic talent of the father lives again and is full of bright promise for the future of his daughter.

THE annual meeting of the supporters of the Herts Seaside Convalescent Home was held at Watford on the 16th ult., when a highly satisfactory report was presented.

THE people of Gateshead propose to establish a Children's Hospital in commemoration of Her Majesty's jubilee.

AMERICAN PUBLIC HEALTH ASSOCIATION.

THE fourteenth annual meeting of the American Public Health Association is to be held at Toronto on Oct. 5th to 8th. The following topics have been selected by the executive committee for discussion: (1) The disposal of the refuse matters of cities and towns; (2) the condition of stored water-supplies, and their relation to the public health; (3) the best methods and the apparatus necessary for the teaching of hygiene in the public schools, as well as the means for securing uniformity in such instruction; (4) recent sanitary experiences in connexion with the exclusion and suppression of epidemic disease. Mr. Henry Lomb, who last year offered prizes for the best essays on sanitary subjects, offers for the present year 1750 dollars to be awarded as prizes on the following subjects: (1) The sanitary conditions and necessities of school-houses and school life; (2) the preventable causes of disease, injury, and death in American manufactories and workshops, and the best means and appliances for preventing and avoiding them; (3) plans for dwelling-houses—(*a*) the cost not to exceed 800 dollars; (*b*) the cost not to exceed 1600 dollars. The local committee of arrangements at Toronto have already actively begun the work essential to a large and successful meeting.

WILLS OF MEDICAL MEN.

THE will and codicil of Mr. John Moulden Burton, surgeon, late of Lee-park Lodge, Blackheath, who died on Feb. 10th last, were proved on March 23rd by Mr. Mark Noble Buttanshaw, and Mr. Herbert Campbell Burton, M.R.C.S., and Mr. George William Burton, the sons, the executors, the value of the personal estate amounting to upwards of £35,000. The testator bequeaths £500 and his furniture and household effects to his wife; his surgical instruments to his son, Herbert Campbell; and legacies to his coachman and another. The residue of his real and personal estate is to be held upon trust to pay the whole income to his wife for life; at her death various legacies are given to his children; and the ultimate residue is to be divided between all his children.

The will and codicil of George Kitching, M.D., late of Enfield, Middlesex, who died on Feb. 2nd last, were proved on March 17th by Mr. Albert George Kitching, M.P., the son, the acting executor, the value of the personal estate amounting to over £19,000. The testator leaves all his real and personal estate upon trust for his wife, Mrs. Mary Ann Kitching, for life; and at her death to and upon trust for his said son.

The will and codicil of Sigismund Sutro, M.D., late of No. 37A, Finsbury-square, who died on Feb. 19th last, were proved on March 17th by Mrs. Helena Sutro, the widow, and Mr. Maurice Gerstley, the executors, the value of the personal estate exceeding £17,000. The testator bequeaths his furniture and effects and £100 to his wife; £1000 to each of his sons; £100 to the German Hospital, Dalston; £1000 upon trust for his brother Max for life; and a complimentary legacy to his executor, Mr. Gerstley. The residue of his real and personal estate he leaves upon trust for his wife for life; at her death he gives a further legacy of £1000 to each of his sons; and the ultimate residue is to be divided between all his children.

The will of Mr. Henry Strangways Hounsell, of Woodlands, Torquay, physician, who died on Feb. 22nd last, was proved on March 15th by Mrs. Emma Nathalie Hounsell, the widow, one of the executors, the value of the personal estate amounting to over £6000. The testator leaves all his real and personal estate upon trust for his wife for life, and then for his two children.

The will and codicil of John White, M.D., of Bath, who died on Feb. 6th last, was proved on March 25th by the Rev. Bedford Hartnell and Mr. Henry Kinneir, the executors, the value of the personal estate amounting to nearly £5000. The testator bequeaths his furniture, plate, pictures, household effects, surgical and medical books and instruments, horses and carriages, to his son William Acramen White; and an annuity of £70 to the Rev. George Hillhouse Helling for life, to be continued to his wife Charlotte if she survive him. The residue of his real and personal estate is to be

Digitized by Google

held upon trust for his said son for life and then for his children.

The will of Mr. Charles Milne, surgeon, of 161, Brixton-hill, who died on Dec. 13th last, was proved on March 29th by Mrs. Elizabeth Milne, the widow and sole executrix, to whom he gives, devises, and bequeaths all his estate and effects, real and personal, for her own use and benefit absolutely. The value of the personal estate exceeds £1300.

The will of Mr. James Henry Brooks, surgeon, of Henley-on-Thames, who died on Jan. 24th last, was proved at the Oxford District Registry on March 30th by Mr. Bransby Brooks, the son, the value of the personal estate being under £1000. The testator, in the events which have happened, leaves all his property, real and personal, to his children.

The will and two codicils of Mr. John MacDonogh, late of No. 15, Clapham-park-road, surgeon, who died on Jan. 9th last, have been proved by Mr. John Frederick Henry Betts, and Mrs. Catherine Jane Betts and Mrs. Annie Emily Mills, the daughters, the acting executors. The testator bequeaths his personal estate to his children. All his freehold lands and hereditaments in the county of Sligo he leaves upon trust for his sister Eliza for life; and then, subject to the payment of £100 to each of his other children, to his son Augustus William.

The following legacies have recently been left to hospitals and other charitable institutions:—Mr. John Field Swinburn, J.P., of Stone Hall, Acocks-green, Worcestershire, three-twentieths of the residue of his property to his trustees to divide in such proportions among such of the hospitals in Birmingham or elsewhere, and such of the schools and churches in Birmingham or elsewhere connected with the Established Church, as they in their discretion shall select as recipients.—Mrs. Harriett Annie Richardson, late of No. 7, Campden-hill-road, Kensington, £1000 to the Hospital of St. John of Jerusalem and St. Elizabeth, 47, Ormond-street, and £30 to the Hospital for Incurables of St. John of God, Seoxton Catterick, Yorkshire.—Miss Frances Caroline Churchill, of Colliton House, Dorchester, £200 to the Dorset County Hospital.—Mr. John Dennison Hargreaves, of Woodlands, Staffordshire, £300 to the Royal Hospital for Incurables.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Recurrence of Enteric Fever in Kidderminster, by Dr. FRANKLIN PARSONS.—The recurrence of enteric fever in Kidderminster led to Dr. Parsons being again instructed to visit and report upon the state of the borough in connexion with this disease. Between August and December, 1884, the estimated number of attacks was 1500, and there were 108 fatal cases. In the first quarter of 1885 the disease had greatly subsided; there were only 3 deaths, and of these 2 were of persons whose illness probably commenced in the previous quarter. In the latter half of 1885 the disease tended again to increase, 35 cases, with 11 deaths, being reported, multiple cases occurring in some houses. The cases were found to have been scattered about the town, with occasional clusters in certain localities. At most of these places sanitary defects were found, more especially house-drains badly trapped and unventilated, or otherwise in bad order; but these defects were at once remedied. Inquiry into the cause of this recurrence failed to associate it with the use of any contaminated milk, and no sufficient grounds have been found for regarding the disease as due to any contamination of the town water at its source. There are, however, intermissions in the supply which are suggestive of danger; and Dr. Parsons gives an instance of this in the house of a medical man whose family have suffered severely, and this notwithstanding the fact that the alterations carried out in connexion with the house-drainage had aimed at securing his dwelling from further danger from without. Dr. Parsons enters into some detail as to the action of the Corporation since the preceding outbreak. The provision of a new water-supply in place of the lower well had been, it was generally understood, decided on; and it will be with some regret that many will learn that this scheme has been abandoned, partly for financial reasons, and partly because it was believed that the well had been made water-tight by a concrete stopping, so that leakage was impossible. The circumstances associated with this lower well were such as to cause some anxiety, and for this reason, rather than because of proof of the fever having been due to any contamination of the general water-service, we should have been glad to learn that all risk had been finally avoided. At this stage Dr. Parsons refers to a joint report which he has made with Mr. Arnold Taylor of the Engineering Department of the Local Government Board; but the latter report does not appear to have been published, and the public are therefore somewhat in the dark as to the value of the concrete lining of this well. The Corporation will, by the provision of a new reservoir, get rid of much of the danger attendant on intermissions in the water-service; several of the main sewers have been relaid; automatic flush tanks and means of ample ventilation have been, and are being, applied to the sewers, and the old catchpits in the course of the sewers have been done away with. A new pattern of ventilator has been tried. It is furnished with a contrivance intended to deodorise the sewer air. This consists of a sieve of asbestos fibre inserted over the opening of the shaft, and dipping at the edge into an annular trough containing a solution of a permanganate. There are two of these sieves, one above the other, and the intention is that the permanganate solution shall rise by capillary attraction and be distributed over the sieves, and that the sewer air in passing between the meshes shall come in contact with it and be deodorised. As a matter of fact, it was found that the red colour of the undecomposed permanganate did not extend more than an inch from the margin of the sieve. Whatever the value of this deodorising contrivance, the arrangement will probably do more harm than good if it hinders the free passage of fresh air into the sewers. Other works have been carried out, since 1884, in connexion with the removal of the nuisances attendant on the midden-privies, but there are other matters which still remain to be adopted. Altogether, the Corporation may be credited with having evinced the desire to remove conditions associated with the serious epidemic of 1884, and the recrudescence in the autumn of 1885 may possibly have been nothing more than such seasonal reappearance of heretofore dormant infection, such as might have been anticipated after an epidemic like that Kidderminster suffered from in the previous autumn.

Diphtheria in the Registration District of Mansfield, by Dr. GRESSWELL.—This is a very elaborate report, embodying a description of the sanitary condition of the towns and villages in the registration district in question, as also an account of the prevalence of diphtheria in them. This disease has somewhat persistently prevailed since 1856 in several portions of the district, and notably in the parishes of Mansfield and Sutton-in-Ashfield, which together embrace more than one-half of the population of the district; and there have been a number of deaths from diseases under the names of which diphtheria, when its existence is as yet hardly suspected, is very apt to be registered. Dr. Parsons had already reported on Sutton-in-Ashfield in 1883, and the total diphtheria deaths during 1882-84 were ninety-eight in number. The disease was found to have been spread by the agency of schools and by means of children congregating in large numbers—even fifty at a time—at funerals and around the houses of former school-fellows who had died of the disease. In fact, as originally pointed out by Dr. Parsons, there had been unrestricted personal communication between healthy and sick, and the chief industry of the place—i.e., the manufacture of stocking hose—afforded peculiar facilities for the transference from family to family of any current infection. Under these circumstances, it necessarily became difficult to say how far the unwholesome conditions under which the people were found to be living, and which are described in detail, co-operated in the production and the diffusion of the infection. But, in addition to this, Dr. Gresswell brings forward a group of cases tending to support the view he has before expressed, to the effect that persons living under the sanitary circumstances he has detailed are liable, after an attack of diphtheria, to suffer almost constantly from a chronic inflammation of the tonsils, and are peculiarly liable to reacquire or to redevelop genuine diphtheria. Neither in Sutton nor in Hucknall-under-Huthwaite, where a prevalence of diphtheria occurred, were any proper arrangements made

Digitized by Google

by the sanitary authority to secure the isolation of the sick. In the rural district of Mansfield most of the diphtheria which has occurred during recent years would appear to have been related, directly or indirectly, to cases in Sutton or in Mansfield, the two chief centres for markets and fairs; and facts were readily forthcoming in illustration of the influence which intercourse with infected persons had had upon the spread of the disease. It is also worth noting that during the period under discussion there was a very general prevalence of sore-throat in the rural sanitary district of Mansfield, concurrent with, and likely enough antecedent to, the diphtheria in Sutton, the disease being variously styled "simple sore-throat," "follicular tonsillitis," and "diphtheritic sore-throat." The malady was associated with a good deal of prostration in those affected, and by some of the medical practitioners it was regarded as infectious. It is not clear what was the relation between this sore-throat prevalence and the diphtheria; but a considerable proportion of those cases which have been recognised as being diphtheritic in the rural sanitary district appear to have been traceable to antecedent cases of the throat affection in Sutton or in Mansfield.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5598 births and 3456 deaths were registered during the week ending April 24th. The annual death-rate in these towns, which had been equal to 20·1 and 20·3 per 1000 in the preceding two weeks, declined last week to 19·8, and was lower than in any previous week of this year. During the first three weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, against 24·1, the mean rate in the corresponding quarters of the ten years 1876-85. The lowest rates in these towns last week were 12·3 in Hull, 13·8 in Leicester, 14·6 in Bristol, and 15·3 in Birkenhead. The rates in the other towns ranged upwards to 26·3 in Bolton and in Manchester, 27·8 in Blackburn, and 34·5 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 363 and 367 in the preceding two weeks, further rose last week to 382; they included 155 from whooping-cough, 114 from measles, 33 from diarrhœa, 30 from diphtheria, 23 from "fever" (principally enteric), 25 from scarlet fever, and 2 from small-pox. No death from any of these zymotic diseases was recorded last week in Halifax, whereas they caused the highest death-rates in Preston, Plymouth, Bolton, and Portsmouth. The greatest mortality from whooping-cough occurred in Manchester, Plymouth, Bolton, and Portsmouth; and from measles in Plymouth, Preston, Bolton, Blackburn, and Portsmouth. The deaths from diphtheria in the twenty-eight towns included 16 in London, 2 in Wolverhampton, 2 in Birkenhead, 2 in Bolton, 2 in Oldham, and 2 in Cardiff. Small-pox caused 6 deaths among the residents of London and its outer ring, 1 in Birkenhead, and not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased in the preceding three weeks from 8 to 16, further rose last week to 17; 6 new cases were admitted to these hospitals during the week, against 3 and 6 in the previous two weeks. The Highgate Small-pox Hospital contained 2 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 348 and 362 in the preceding two weeks, declined last week to 318, and were 97 below the corrected weekly average. The causes of 74, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, Portsmouth, Brighton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined in the preceding five weeks from 27·9 to 20·5, was 20·7 in the week ending April 24th, and exceeded by 0·9 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·1 in Perth and 13·9 in Paisley, to 22·1 in Aberdeen and 25·0 in Glasgow. The 511 deaths in the eight towns showed an increase of 4 upon the number in the previous week, and included 15 which were referred to whooping-cough, 9 to measles, 9 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 3 to scarlet fever, and not one to small-pox; in all, 46 deaths resulted from these principal zymotic diseases, against numbers declining from 62 to 34 in the preceding four weeks. These 46 deaths were equal to an annual rate of 1·9 per 1000, which was 0·3 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had declined in the four previous weeks from 29 to 10, rose again last week to 10, of which 14 occurred in Glasgow. The 9 fatal cases of measles showed a further increase upon recent weekly numbers, and included 4 in Edinburgh and 4 in Leith. The 9 attributed to diarrhœa, on the other hand, corresponded with the number in the previous week, and were 5 below the number in the corresponding week of last year. The 5 deaths referred to "fever," including 2 in Glasgow, showed an increase of one upon the number in each of the previous two weeks. Of the 5 deaths from diphtheria 3 occurred in Glasgow and 2 in Edinburgh, and all the 3 fatal cases of scarlet fever were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 109 and 122 in the preceding two weeks, declined last week to 100, and were 18 below the number returned in the corresponding week of last year. The causes of 63, or 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had steadily declined in the preceding five weeks from 40·5 to 25·0 per 1000, rose again to 27·3 in the week ending April 24th. During the first three weeks of the current quarter the death-rate in the city averaged 28·4 per 1000; the mean rate during the same period did not exceed 19·3 in London and 17·6 in Edinburgh. The 185 deaths in Dublin last week showed an increase of 15 upon the number in the previous week, but included only 8 which were referred to the principal zymotic diseases, against 16 in each of the previous two weeks; 4 resulted from whooping-cough, 3 from "fever," 1 from diarrhœa, and not one either from small-pox, measles, scarlet fever, or diphtheria. These 8 deaths were equal to an annual rate of 1·2 per 1000, the rates from the same diseases being 2·4 in London and 1·8 in Edinburgh. The fatal cases of whooping-cough, which had declined in the four previous weeks from 12 to 5, further fell last week to 4. The 3 deaths referred to "fever" corresponded with the number in each of the previous two weeks. Only one death was attributed to diarrhœa, against 3 in the previous week. Five inquest cases and 2 deaths from violence were registered; and 78, or considerably more than a third, of the deaths were recorded in public institutions. The deaths of infants were fewer than in any recent week, while those of elderly persons showed an increase upon the low number in the previous week. The causes of 20, or nearly 11 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon George Campbell, to the *Euphrates*: and Staff Surgeon Robert Bentham, to Chatham Hospital, temporary; Surgeon Samuel Keays, to the *Royal Adelaide*.

YEOMANRY CAVALRY.—Derbyshire: Surgeon Frederick W. Wright resigns his commission.

ARTILLERY VOLUNTEERS.—1st Devonshire: Acting Surgeon E. J. Domville resigns his appointment.—1st Lincolnshire: Surgeon Thomas Newby, M.D., is granted the honorary rank of Surgeon-Major.—2nd East Riding of Yorkshire: William Barter, Gent., M.D., to be Acting Surgeon.—1st North Riding of Yorkshire: Acting Surgeon Geo. Pilkington resigns his appointment.

RIFLE VOLUNTEERS.—4th Volunteer Battalion, the Devonshire Regiment: Surgeon Joseph Harper is granted the honorary rank of Surgeon-Major.—1st Durham: Surgeon S. W. Broadbent is granted the honorary rank of Surgeon-Major.—3rd Durham (the Sunderland): Acting Surgeon R. J. Collie, M.D., to be Surgeon.—1st Volunteer Battalion, the

Digitized by Google

Prince of Wales's (North Staffordshire Regiment): Surgeon W. Dawes is granted the honorary rank of Surgeon-Major.

VOLUNTEER MEDICAL STAFF CORPS.—Surgeon W. H. Platt is granted the honorary rank of Surgeon-Major; Richd. James Reece, Gent., to be Surgeon.

Correspondence.

"Audi alteram partem."

THE EXAMINATION IN MATERIA MEDICA AT THE ENGLISH CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—That the Royal Colleges of Physicians and Surgeons should have limited their demands from candidates for examination in materia medica is a change which is in accordance with the almost unanimous opinion of those who have formed any opinion on the subject; but a careful study of the synopsis and schedule for the first combined examination, issued on the 11th ult., yields some results which are rather astonishing.

The principle of scheduling the more important drugs is excellent, and the limitation of the practical part of the examination is also good; but the details are surely open to criticism. There are only twenty drugs in the whole Pharmacopœia with the physical properties of which the candidate is expected to show practical familiarity. A medical student who is unable to recognise, for instance, any preparation of ammonium, sodium, or potassium (saving only the permanganate), who cannot identify nitrate of silver, or any salt of iron, or nitrous ether, quassia, glycerine, tannic acid, gallic acid, camphor, turpentine, nitrite of amyl, cantharides, or cod-liver oil, need have no fear, it would seem, of failing to pass a practical examination in materia medica at the new Examination Hall. He must be aware of the dose and use of quassia, but not necessarily of those of gentian or calumba. He is excused any knowledge of the appearance, dose, or use of nitrate of potassium, podophyllin, copaiba, creasote, cubebs, santonin, pepsin, croton oil, or even castor oil. He must recognise the chlorides of mercury, and have theoretical acquaintance with its oxides and iodides (although only one iodide is now officinal); but he is no longer required to give any account of "blue pill," "blue ointment," or "grey powder" (unless these are supposed to be included under oxides of mercury). The white precipitate and the nitrate would also be beyond his ken.

The gratitude of the students will be unbounded. Such are some of the results of the combined wisdom of the two learned Colleges. It was open to them to ask for a really useful practical acquaintance with the Pharmacopœia of every-day practice, or, on the other hand, to omit all practical examination. For either of these courses something might be said, but what can be urged in favour of the present arrangement it is difficult to see. It can scarcely be expected to be permanent.

During the last few years the staff of each medical school has had to make an almost annual rearrangement of the curriculum to meet the continual variations in the demands of licensing bodies, but we should count the labour light if it were possible to perceive a steady approximation to a settled and satisfactory system.

I am, Sir, yours obediently,
JOHN B. HELLIER, M.D. Lond.,
Lecturer on Materia Medica and Therapeutics in the Yorkshire College.

Leeds, April 24th, 1886.

THE PRIZE SYSTEM.

To the Editor of THE LANCET.

SIR,—Your columns announce earlier than usual the attractions the medical schools have for students. Prizes and exhibitions appear in great numbers. I send you an extract from the evidence given by Sir Benjamin Brodie before the commissioners appointed to inquire into the regulations affecting the sanitary condition of the army, upon being asked what he thought as to giving prizes to medical students. Few teachers had more experience of the question of medical education. It would be interesting to know the opinions of the present race of medical teachers, and whether there are any records of the comparison between those who pass their examinations and those who are "referred" as to being prizemen. Sir Benjamin says:—

"I have much doubt myself about giving competitive prizes in examinations. It may work well in schools and colleges, but when you come to professional examinations (I do not speak about the Civil Service) I do not think that competitive prizes will answer; for, after all, they will be obtained chiefly by those who are crammed, by the men of good memories, and not by those who work. It seems to me that the man who thinks will not have the advantage that he ought to have. I would limit the prizes to one class founded upon cases. I believe the ordinary prizes do very little good. For some time past the teachers in the medical schools have been in the habit of giving prizes to students, yet, notwithstanding this, they are found to be not so well qualified for examination at the College of Surgeons as they were twenty years ago; and hospital surgeons and teachers are now satisfied that these prizes do no good; nay, more than that, that the best men do not get them. These prizes operate in this manner: a man wants a prize; he gets books, reads up the subject, and this kind of work keeps him out of the dissecting-room and the wards of the hospital. Yet these are the only places where he can get knowledge that he can apply to practice, and learn to observe and think."

I am, Sir, yours &c.,
F.R.C.S.

April, 1885.

MR. KNOWSLEY THORNTON'S CASES OF SPLENECTOMY.

To the Editor of THE LANCET.

SIR,—Four years ago, when by your indulgence I presumed in the pages of THE LANCET to condemn splenectomy in leucocythæmia as a "useless and deadly experiment," and at the same time published the records of twenty-nine cases in which the operation had been performed in different parts of the world (during a period of 333 years), and called attention to what up to that date appears to have escaped the notice of operators, the "fearful fatality" of the measure in leucocythæmia, testified to by the fact that "whereas out of thirteen splenectomies in which leucocythæmia was absent no less than eight recoveries were recorded, out of the sixteen in which the latter disease was present there was no instance in which the patient recovered even from the primary effects of the operation"; and when I was also indiscreet enough to regard the operation as altogether unjustifiable in the light of these statistics, and to employ arguments to this effect in reply to a leading surgeon, who took me to task for my rashness,—I regret to say that no high surgical authority then came forward to support my too feeble voice. Although the leading surgeon above referred to did not perform splenectomy in the case of leucocythæmia then under his care, which at first he thought of doing, and although several eminent gentlemen expressed doubts as to the use of the operation in leucocythæmia in the discussion that followed Mr. Warrington Haward's case of splenectomy read before the Clinical Society (*vide* THE LANCET, April 1st, 1882), and Mr. Haward himself declared, in speaking of his case, that he should not have consented to operate had the newly published statistics been then before him, still it is only within the last few days that splenectomy has been distinctly condemned as unjustifiable in leucocythæmia by an authority of Mr. Knowsley Thornton's standing.

But what additional evidence have we obtained since February, 1882? Six splenectomies have been recorded during the four years which have intervened since that date. Out of these, five have been performed for diseases of the spleen, unassociated with leucocythæmia (Knowsley Thornton two, one recovered, one died; Billroth, of Vienna, one, recovered; Spanton one, died; Credé, of Dresden, one, recovered), two of which died and three recovered; and one for leucocythæmia (by Franzolini, of Turin), which, contrary to the assertion of Mr. Knowsley Thornton, who recently stated at the Medical and Chirurgical Society "that all the cases in which leukæmia was present were fatal," recovered, and four months afterwards the leucocythæmia, which had gradually subsided since the operation, had entirely disappeared.

Digitized by Google

Now, although these cases by no means strengthen the position I assumed on this question four years ago, I think I may fairly congratulate myself that I am not now alone in the opinion which I still entertain.

I am, Sir, yours faithfully,

Yarmouth, April 23rd, 1886. H. COLLIER, M.D. (Brux.)

INTRA-UTERINE AMPUTATION, WITH OTHER DEFICIENCY OF PARTS.

To the Editor of THE LANCET.

SIR, Having been in harness for a good many years as a general practitioner, it has been my lot to have had a good share of midwifery, but, of all the cases I ever attended, I never met with an instance of such a marked deficiency in a newly-born babe as I did on April 5th.

Mrs. W——, aged twenty-two, a primipara, who had been under my care for six weeks previously, suffering from false pains now and again, with a sanious, glutinous discharge, was on that date seized with labour. Upon examination, the os was found fully dilated and the breech presenting, and on passing my right index finger over the hip the left limb was easily brought down, which was perceived to be amputated nicely at the middle third of the leg, and the stump firmly healed, apparently a successful case of circular operation. In my attempt to bring down the other, it was felt to be stiff and unyielding; a steady traction was therefore applied to the stump, by which means the little fellow was soon launched into the world. According to the young mother's calculation, her son and heir had made his appearance about a month before its proper time; however, he looked bright and intelligent enough, though he presented the following oddities, in addition to the amputated leg: the right lower limb was straight as an arrow from the hip to the ankle, the knee ankylosed, and the rotundity of the structures of both thigh and leg lost, the foot twisted upon itself inwards (talipes varus), and the toes simply in a rudimentary state; the limb was constantly kept firmly flexed to the right shoulder, soldier-like, presenting "shoulder arms," substituting in this instance the leg for the arm. As for the left, or amputated leg, it was firm and well developed, and moved about with the greatest alacrity. The right hand had the index, the long, and the ring fingers fully developed, with the thumb and the little finger in a rudimentary state. Again, the left hand had only the index and the long fingers intact, a trace simply of the others left. A search was now made for the missing or amputated part, which was found along with the placenta expelled, a plump waxy-looking piece, sufficiently formed to ascertain that the foot corresponded with its fellow—i.e., clubbed. Finding the little fellow so sadly equipped for the battle of life, those most intimately connected were very anxious to know whether he might or not cease to exist. However, to the greatest relief of all concerned, he died naturally four hours subsequently.

I am, Sir, yours faithfully,

Brynmeurig, Bethesda, April 10th, 1886. JOHN WILLIAM.

ROTHELN: A POINT OF DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Glover, in THE LANCET of April 24th, mentions a case in which he detected an enlarged gland in the neck appearing *before* an attack of rötheln, and throws out the suggestion that in an epidemic of this disease this condition may enable us to diagnose rötheln before the rash appears.

Lately we have had an epidemic here of rötheln in a large school that I attend, thirty-two boys in all being attacked, and of these five or six had swelling of the cervical glands for several (four or five) days before the rash appeared, and one boy had swollen glands, but no rash at all ever showed itself. Fully half the boys attacked had enlargement of the cervical glands *after* the rash disappeared, one of the usual sequelæ. As far as I can find out, very few English writers on medicine give a good description of rötheln. The best and truest of the accounts I have come across is in the Practice of Medicine by the late Dr. Fagge, and that is copied from the German (Ziemssen's Handbuch).

I am, Sir, yours faithfully,

York, April 25th, 1886. W. H. JALLAND.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY GRADUATION CEREMONIAL.

ON the 21st inst. the Annual Graduation Ceremonial in Divinity, Arts, Law, and Science took place in the United Presbyterian Synod Hall, which is placed at the disposal of the University authorities for their more important academic gatherings. Lord Inglis, the Chancellor of the University, presided over a crowded meeting of University *alumni* and of the general public. The interest of the occasion was greatly enhanced by the presence of a number of distinguished men on whom the honorary degrees of the University, D.D. and LL.D., were about to be conferred. Prominent amongst these was Dr. Mouat, distinguished alike by his medical, scientific, and administrative achievements in British India, a graduate of Edinburgh of nearly fifty years' standing, who was very warmly received on his presentation for the LL.D. degree. An enthusiastic reception was also accorded to Sir Charles Wilson, the Oriental scholar and explorer, and the hero of the Upper Nile, who presented a most distinguished appearance in his military attire, resplendent with the innumerable medals and orders of which he is the honoured possessor. Sir Charles Nicholson, formerly Chancellor of the University of Sydney, Emeritus Professor John Wilson, of the Chair of Agriculture in Edinburgh, and Mr. John Small, the University librarian, were also amongst those who had the honorary LL.D. degree conferred upon them. A large number of Masters of Arts, Bachelors of Divinity, and Doctors and Bachelors of Science were then capped by the Chancellor.

PROFESSOR BUTCHER'S ADDRESS.

Professor Butcher, of the Chair of Greek, then addressed the assembled graduates, choosing for his subject the "Unity of Learning, its relation to the Life of the Nation, and the Narrowing Effect of too Highly-developed Specialisation." Referring to the Faculty of Arts, he characterised it as a token of the unity of all learning, dealing as it does with those studies which may be included under the title of Philosophy, and related on the side of Ethics and History to the Faculties of Law and Theology, and on that of Mathematics and Physics to the Faculty of Medicine. It is thus the opponent of that spirit of specialism which the professor complained is now supposed to have superseded the spirit of philosophy, and which has not only annexed the several sciences, but has pushed itself also into the domain of morality. Here it shows itself in the form of a departmental supervision exercised over morality in its several aspects; but as, though there be many virtues, there is one unity of Righteousness, so, though there be many branches of science, there is one unity of Knowledge. The more the number of the special sciences is augmented the greater is the danger that they will become mere *disjecta membra* of knowledge, unless this tendency is held in check by the influence of some system of constructive thought which will harmonise their results and reduce to unity their highest generalisations. In applying this principle to the study of medicine, Professor Butcher took the opportunity of combating the opinion of Professor Huxley, recently expressed, to the effect that there might in certain conditions be a danger of broadening the significance of M.D. into "Medical Dilettante." He quoted the dictum of Galen, that "the best physician is also a philosopher," as one that would command the general assent of the profession, and he pleaded that, however skilled a man may be in his own craft, he should not let that craft usurp the whole universe. The remainder of the address dealt with the popularisation of learning, as distinguished from its vulgarisation, and the means of attaining it, and concluded with a strong plea in favour of co-operation in teaching, instead of pure competition, as the principle upon which the requirements of true learning are most beneficially fulfilled.

UNIVERSITY COURT.

It has been decided by the University Court that the University shall in future confer a degree in Music, and shall give diplomas for schoolmasters, a first step towards the formation of a "Faculty of Education."

EDINBURGH ROYAL HOSPITAL FOR SICK CHILDREN.

Sir Alexander Christison, Bart., M.D., has been appointed a manager of this Hospital, in the room of the late Dr. Angus

Macdonald. The vacant post of assistant-physician to the Hospital has not yet been filled up; a number of candidates for the appointment have submitted applications and testimonials to the Board of Directors, and it is expected that the appointment will be made within a few days.

Edinburgh, April 29th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

YESTERDAY (Wednesday) there was a large gathering of the Fellows and distinguished visitors to witness the conferring of the Honorary Fellowship of the College on Professors Huxley and Pasteur, Sir James Paget, Sir Joseph Lister, Sir Spencer Wells, and Mr. J. Marshall, the unveiling of the Dease statue, and the opening of the Butcher Museum. His Excellency the Lord-Lieutenant, the Countess of Aberdeen, and the Prince and Princess of Saxe-Weimar having arrived at the College, a procession was formed, which passed up the grand staircase and through the anatomical museum into the board-room. Sir Charles Cameron, the President, in an able speech, dwelt on the merits of the six gentlemen upon whom the College had conferred the Honorary Fellowship, and introduced Sir James Paget, Bart., the only one of the Honorary Fellows present, the others being prevented by unavoidable circumstances from attending. It was expected that Mr. Marshall would have been there, but an attack of bronchitis almost at the last moment caused his absence, while the death of Lady Wells rendered the presence of Sir Spencer Wells impossible. The diploma of Fellowship (*honoris causâ*) having been conferred on Sir James Paget, a suitable reply was returned by that gentleman. Mr. William Stokes, the Vice-president, in a short but eloquent speech, then handed to his Excellency the first copy of the "History of the College," edited under the authority of the College by Sir Charles Cameron. Mr. Rawdon Macnamara, representative of the College in the General Medical Council, next moved a vote of thanks to their Excellencies, which was seconded by Sir George Porter, Surgeon-in-Ordinary to Her Majesty, and acknowledged in appropriate terms by the Lord-Lieutenant. Mr. McDonnell moved, and Mr. Wharton seconded, a vote of thanks to the Prince and Princess of Saxe-Weimar for their presence there that day, and the Prince having replied, the procession was re-formed and returned to the entrance hall. The President having briefly referred to Mr. Dease, one of the founders of the College and its first professor of surgery, requested the Countess of Aberdeen to unveil the statue, after which his Excellency declared the Butcher Museum open, and the proceedings terminated.

A meeting of the Council will be held next Tuesday, to elect examiners for the ensuing year. I understand that of those elected last year two at least will not seek re-election. The history of the College and of Irish surgery and medicine, which has been compiled by Sir Charles Cameron and will be published by authority of the College, will shortly be issued, and it is understood that any surplus accruing from the sale of the work will be handed over to the Royal Medical Benevolent Fund Society of Ireland. In addition to a history of the College the work will contain: firstly, an account of the medical books published in Ireland up to the beginning of the nineteenth century; secondly, a history of the Dublin Guild of Barber Surgeons; thirdly, an account of medical teaching and examination in Ireland prior to the foundation of the College; fourthly, biographical sketches of the Presidents of the College; fifthly, an account of the College and private schools of anatomy and surgery; and sixthly, more than 300 biographical sketches of the professors of the College and the teachers in the private schools.

ADELAIDE HOSPITAL, DUBLIN.

The Committee of Management have undertaken the erection of a home for the nursing staff and apartments for the lady superintendent on the site of the house formerly used for the compounding of medicines. When completed it will be found of great benefit to the hospital. From the annual report, it appears that the hospital obtained during the year £6599, which included a sum of £712 from pay patients. The institution is admirably managed, and well deserves the support it receives.

HEALTH OF DUBLIN FOR MARCH QUARTER.

The deaths recorded in the Dublin registration district were equal to 33·4 per 1000. As regards the respective rates of mortality in the several grades of the population, it appears that the deaths in families of the "professional and independent class" were equal to 17·5; in the "middle class," 32·1; among the "artisan class and petty shopkeepers" it was 26·5; and in the "general service class" and the "inmates of workhouses" combined, it was 43·2 per 1000 of the population.

ACTION AGAINST THE LOCAL GOVERNMENT BOARD.

Dr. Hugh Davies, late medical officer of the Newport Workhouse, was appointed to this office in 1874, but by an order made by the Local Government Board last September the Newport Union was dissolved and amalgamated with the Westport Union. He applied to the guardians for compensation for the loss of his appointment, which was refused; and he finally entered an action against the Local Government Board for £3000 damages. This was decided in favour of the Board last week, as it was proved that there was no contract of service between the parties, and that the defendants had acted within their legal rights in dissolving the union. Dr. Davies, besides being refused any compensation, will have to pay the costs of the action.

By the death of Dr. Taggart a vacancy has arisen for the Coronership of the Southern Division of the County of Antrim, and two medical practitioners are candidates for the post—viz., Dr. McNinch, of Ballyclare, and Dr. Wilson, of Kells.

The Belfast Corporation are about to borrow £20,000 from the Board of Public Works in order to defray the cost of erecting a free public library in that town.

Dublin, April 29th.

Obituary.

EVORY KENNEDY, M.D., T.C.D.

ON Good Friday the subject of this notice passed away at the ripe age of seventy-eight. Dr. Kennedy practised formerly in Dublin as an obstetric physician, and was an ex-Master of the Rotundo Lying-in Hospital. He was a Justice of the Peace and Deputy Lieutenant for the county of Dublin, and held a high position in the city, in which he practised. He obtained the degree of Doctor of Medicine of the University of Edinburgh in 1827, and of the University of Dublin in 1839, and the same year was elected a Fellow of the College of Physicians in Ireland, of which he became the President in 1854–5. He filled various posts with credit and efficiency, among others that of President of the Irish Medical Association and Consulting Physician to the Dublin Eye and Ear Infirmary. He was a Corresponding Member of the Medical Society of Hamburg, Vice-President of the Société d'Afrique, Paris, Honorary Member of the Hunterian Society, Edinburgh, Honorary Fellow of the Edinburgh Obstetrical Society, &c. His contributions to medical literature included: "On Utero-placental Circulation and Placental Souffles," "Vesico-vaginal Fistula," "Tartar Emetic in Obstetric Practice," "Purpuric Puerperal Fever," and an excellent monograph on "Congestion, Inflammation, and Ulceration of the Uterus," published in the *Dublin Medical Journal* in 1847.

SURGEON-MAJOR TAGGART, M.D.

GENUINE and genuine sorrow was felt in Carrickfergus on Saturday evening, April 10th, when it became known that Dr. Taggart had passed away, and shutters were immediately put up in every shop window, whether great or small. The sad event was not unexpected, as the deceased gentleman had been in declining health for a considerable time past, and some weeks ago it was known that, notwithstanding the care bestowed on him by several of the most eminent medical men in Ulster, his recovery was hopeless, rapid consumption being the cause of death, at the comparatively early age of forty-seven years. Dr. Taggart was the son of the late William Taggart, Esq., of Thornhill, Antrim. He was educated at the Queen's College, Belfast, and held his degree of M.D. from the Queen's University in Ireland; he was

Digitized by Google

also a licentiate of the Royal College of Surgeons of Edinburgh. He came to Carrickfergus in the year 1859, and by his courteous manner, gentlemanly deportment, and skill in his profession, he soon built up an extensive and lucrative practice. He was coroner for the southern division of county Antrim, and also for the county of the town of Carrickfergus, and the sometimes trying and difficult duties in connexion with these offices were discharged by him with the utmost impartiality. He succeeded the late Dr. L'Estrange as surgeon-major of the 2nd Brigade, North Irish Division, Royal Artillery, and was a general favourite with his brother officers and the men. He also held the post of certifying factory surgeon for the Carrickfergus district and surgeon to the Sheil's Almshouses, Carrickfergus. In politics Dr. Taggart was a moderate Conservative, and at the last contest in the month of November he was returned in the Conservative interest as one of the municipal representatives, but he did not long enjoy the honour thus won, as the entire election was soon set aside by the Court of Common Pleas, and a new one ordered, which has not yet been held. The deceased leaves a widow and five children, for whom much sympathy is felt in the bereavement they have sustained.

JOHN MATTHEWS, M.D. ST. AND., L.S.A.

THE friends of Dr. Matthews, of Colebrook-row, Islington, were painfully surprised on Monday morning to find his death announced in the obituary of the daily papers. Though he was seventy-three years of age, he did not seem so, and might have been seen till within a few days of his death actively walking his round. He died of pneumonia, which has been so fatal this year, and which there is reason to believe he incurred by close attention to a little patient with a similar attack, to whom he paid evening as well as morning visits. Dr. Matthews will be greatly missed, not only by his patients, to whom he was a thoughtful and valuable adviser, but by his medical friends and neighbours, who often benefited by his kindness and intelligence. He was one of the oldest and most valued members of the Islington Medical Society, and frequently contributed interesting facts in the discussion of cases. Dr. Matthews was born in London and was the son of Dr. John Burggreen Matthews, M.D. Edin., who at one time practised in Canada, and the grandson of Lieutenant John Matthews, R.N., author of "A Voyage to the River Sierra Leone," and, if we mistake not, Governor of that Colony. Dr. Matthews was educated at the High School, Edinburgh, and at Dawlish. He received his medical education at St. Bartholomew's. He was tall in stature, of strong physical constitution, and, though of somewhat sensitive temper, was thoroughly upright and kind. He was thoughtful and well read. His religious views were broad. He was well-known in connexion with the microscope. In the year 1874-5 he was President of the Quekett Microscopical Club, to which he contributed many papers: one on the History of Corals, another on an instrument which he called the "Micro-megascope." He also invented an instrument for cutting hard sections. He edited the second edition of "Davies on the Microscope." Dr. Matthews had a very decided mechanical gift, and if there was any other profession which he would have adorned and liked more than his own, it was that of an engineer. He leaves a wife and one child to mourn his death, which will be felt too by his professional brethren in Islington, who greatly respected him.

WILLIAM RAYNER, M.D.

THE late Dr. Rayner of Stockport, whose death we have already announced as having occurred on April 8th, was born in Stockport, and received his professional education at University College, London, and Middlesex Hospital, being in 1832 admitted a member of the Royal College of Surgeons of England and a licentiate of the Apothecaries' Society. After a brief attendance at the hospitals of Paris, he returned to England and settled down to the practice of his profession in his native town. In 1841 he took the degree of M.D. at the London University, and since Dr. Storrar's death he was one of the oldest, if not absolutely the oldest, of those possessing that degree. In 1853, and again in 1854, Dr. Rayner was elected Mayor of Stockport, and subsequently for eighteen years he served the town in the capacity of an alderman, his position being largely that of an adviser, particularly in regard to matters affecting the public health. In 1855 he was placed on the Commission of the Peace for the borough, and was appointed subsequently a magistrate for the county of Lancaster. Dr. Rayner was a vice-president of the Stockport Infirmary, and also filled at one time or other almost every local office of influence or importance that either ability could attain or the suffrages of others could confer upon him.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on April 21st:—

Armstrong, Sidney Joseph, L.K.Q.C.P.I., Wakefield.
Arnold, Francis Sorell, Oxford.
Baker, Walter Robert, L.R.C.P. Lond., Kilburn.
Bennett, Frank Albert, L.S.A., Birmingham.
Davidson, Harold, L.R.C.P. Lond., Forest Gate.
Hare, Edward Christian, L.R.C.P. Lond., West Bath.
Henderson, James Threapland, L.S.A., Witney.
Lawson, Bernard Sloane, L.R.C.P. Lond., Harley-street.
Oliver, Francis George, L.R.C.P. Lond., Nejapatain, India.
Riddell, Andrew Wilson, L.R.C.P. Lond., Bristol.
Roome, Stanley Molesworth, L.R.C.P. Lond., Cork.
Tabor, Charles James, L.R.C.P. Lond., Reading.

Admitted on April 22nd:—

Bett, William, Holbeach.
Brodrick, Harry Edward, Bury St. Edmunds.
Bright, Eustace Frederick, Bournemouth.
Burton, Leonard William, Burton-on-Trent.
Chapman, Robert Hugh, Richmond
Colman, Walter Stacy, Peterborough.
Collingwood, George Trevor, Brockley.
Cundall, Thomas William, York.
Deacon, George Edward, Methersett.
Gough, Henry Edward, Manchester.
Graham, William Percival Gore, Cambridge.
Greenwood, William, Ossett.
Halsted, George Ezra, Newark.
Joly, Joseph Eugene Numa, L.R.C.P. Lond., Oppidem-road.
May, Chichester Gould, Dublin.
Nairn, Robert, Kennington-road.
Redmayne, Thomas, Newcastle-on-Tyne.
Smith, Frank Wyatt, B.A. Cantab., Sherborne.
Tatham, Ernest John, Highgate.
Trevor, Edward Fitzgerald, Harlesden.
Turner, Clifford Winslow, Leeds.
Walker, John Thomas, Rexborough.
Webster, Percy Samuel, L.R.C.P. Lond., Lincoln.
Williams, George Rowland, L.R.C.P. Lond., Stroud-green.
Woakes, Arnold Beaumont, Hanley-street.

Admitted on April 26th:—

Blomfield, George Wills, L.S.A., Hastings.
Bowden, Walter, Hilldrop-crescent.
Cholmeley, Henry Patrick, Duke-street, Adelphi.
Colquhoun, William Brooks, L.R.C.P. Lond., Upper Clapton.
Cross, Robert George, Petersfield.
Davis, George William, L.R.C.P. Lond., York-road.
Dixson, Charles Frederick Lyne, Camden-road.
Evans, William Edward, Torquay.
France, James Mead, Guildford-road.
George, William Hotten, Probus, Cornwall.
Georges, Absalom, Percy-circus.
Hill, Walter James, Bath.
Howell, Arthur Anthony, Wrexham.
Lyster, Arthur Edward, L.S.A., Walthamstow.
Michelmore, George, Gloucester-street.
Pagden, Trayton Charles, Epsom.
Spoor, William Joseph, Gloucester-place.
Tredinnick, Albert Stephen, St. Austell, Cornwall.
Walker, Cyril Hutchinson, Great Yarmouth.
Wallis, Charles George, Woolwich.

Admitted on April 27th:—

Bidwell, Lawrence, L.R.C.P. Lond., Lee-terrace, Blackheath.
Burnside, Eustace Augustus, L.R.C.P. Lond., Richmond-road.
Clay, William Rudolph, L.R.C.P. Lond., Westwick-gardens.
Evans, Charles Hotham, L.R.C.P. Lond., Winchmore-hill.
Gore, Alfred Joseph, L.R.C.P. Lond., Victoria, Australia.
Langton, Charles Baring Tyndal, L.R.C.P. Lond., Medora-road, Brixton.
Parker, Charles Arthur, L.S.A., Claxby, Lincolnshire.
Sprigge, Samuel Squire, Milner-terrace.
Ward, Stanley Edward, L.S.A., Haverhill, Suffolk.

Admitted on April 28th:—

Bockell, Edward, L.R.C.P. Lond., Ramsey.
Christmas, Charles Denn, L.S.A., Hammersmith.
Daniels, Charles Wilberforce, M.B. Cantab., Manchester.
Fisher, Alfred, L.R.C.P. Edin., Liverpool.
Grenfield, Henry Osborne, L.R.C.P. Lond., Calstock, Cornwall.
Holyoake, Hubert, L.R.C.P. Lond., Droitwich.
Melhuish, John, L.S.A., Crossfield-road.
Mitchell, Walter Frederick, L.S.A., Granville-square.
Nevins, John Ernest, L.S.A., Liverpool.
Norman, Frederick, L.R.C.P. Lond., Tavistock-street, Bedford.

Digitized by Google

Rigden, Alan, L.R.C.P. Lond., Thurlow-place.
Thomas, Thomas Nash, L.S.A., Solva, Pembrokeshire.
Vallance, Ernest, L.R.C.P. Lond., Stratford.
Varley, George, Stanningley.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the Examiners, held in Glasgow, the following candidates passed the respective examinations for the triple qualification conferred by the three Scottish medical corporations:—

FIRST EXAMINATION.—John A. Calderwood, Arthur F. Crinan, Luther Watson, and R. P. Williams, Glasgow Medical School; A. H. H. Watson and M. Campbell Wright, Edinburgh School; H. C. Pauli and G. C. Giles, Leeds School; Walter Cheadle, Owens College; John Stewart and William A. Wales, Queen's College, Belfast; E. S. Leyburn, Dublin; and M. V. C. Marquis, Bombay.

SECOND EXAMINATION.—C. Carruthers, J. F. Challinor, G. Evans, John Rogerson, J. Kenrick Jones, and Archibald M'Arthur, Glasgow School; Alfred A. Adie and M. C. Wright, Edinburgh School; W. F. Cooper, Queen's College, Birmingham; Louis P. Jackson, King's College, London; Daniel Henderson, Queen's College, Belfast.

THIRD EXAMINATION.—William Ed. Bennett, Leeds School; William Colquhoun, Arnold Edward Thorpe, and Horace K. Young, Glasgow School; George Robert Nelson and John Wingfield, Edinburgh School.

The following were admitted Licentiates of the Royal College of Physicians and the Faculty of Physicians and Surgeons of Glasgow under the regulations in force prior to October, 1884:—

George W. Eglinton, Liverpool School; Ed. J. Foulston, Leeds School.

ST. ANDREWS UNIVERSITY.—The following registered medical practitioners having passed the required examinations, received the degree of M.D. on April 21st:—

Adam, Edward, M.R.C.S., L.K.Q.C.P.I., Liverpool.
Boustead, Robinson, M.R.C.S., F.R.C.S. Ed., L.S.A. Lond., Brighton.
Bowie, Alex., M.B. C.M. St. And., L.R.C.P., L.R.C.S. Ed., London.
Davis, H., L.R.C.P. Lond., M.R.C.S., L.S.A. Lond., Wallington.
Gunn, Alexander, L.R.C.P., L.R.C.S. Ed., Edinburgh.
Hume, Frederick Henry, M.R.C.S., L.S.A. Lond., London.
Knight, Charles Frederick, M.R.C.S., L.S.A. Lond., London.
Macdonald, Keith Norman, L.R.C.P. Lond., F.R.C.P. Ed., L.R.C.S. Ed., Cupar Fife.
McMunn, J. Alex., M.B. C.M. St. And., L.R.C.P., L.R.C.S. Ed., Alderney.
Scowcroft, J. Edwin, L.R.C.P., F.R.C.S. Ed., F.F.P.S. Glasg., Bolton.
Skirtliff, E. Matthew, M.R.C.S., L.S.A. Lond., Kingston-on-Thames.
Willson, Henry, M.R.C.S., L.S.A. Lond., London.

ABERDEEN UNIVERSITY.—At the recent examinations for medical and surgical degrees, the following candidates obtained the degree of M.D.:—

John Hector Anderson, M.A., James Mackenzie Booth, M.A., William Geddie, John Inglis, M.A., Peter William M'Donald, M.A., Forbes Robertson Mutch, M.A., John Reid, M.A., James Taylor Robb, M.A., William Stericker, M.A., Peter Alfred Sullivan, M.A.

The following candidates obtained the degrees of M.B. and C.M.:—

Charles Mitchell Aird, Henry Angus, Charles Arthur Arnold, Joseph Marshall Barnes, John Fairbairn Binnie, M.A., Gregor Burgess, A. Wilson Chapman, Alexander Forbes Chisholm Clark, Frank Lang Collie, William Davidson, James Steel Dickie, *John Charles Grant Duffus, M.A., George Forbes, †James Galloway, M.A., W. Greig, Alex. Gordon R. Ingram, M.A. J., Thomson Lewis, Philip J. Lumsden, Donald George Gordon Macdonald, John Malcolm, †William Milligan, Alexander Milne, Alfred Mackay, †James Murray, Charles Reid, John Russell, M.A., William Scatterty, M.A., David Alexander Shirres, Alexander Simpson, M.A., John Wesley Smith, Robert Ben Tydd Stephenson, John Taylor, *John Duncan Thomson, M.A., William Donald Urquhart, George Williamson, M.A., Reginald Graham Wills, George Nicol Wilson.

* Highest Academical Honours. † Honourable Distinction.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on April 22nd:—

Alexander, Sidney Robert, Essex Lodge, Upper Norwood.
Fowler, John Bucknill, Thornton, Hereford.

AN interesting work on medical curiosities and history has been published in Spanish from the pen of Don Luis Comenge.

ON April 21st, Dr. Charles M. Chadwick delivered a lecture on Pasteur and his Work, to the members of the Leeds Philosophical Society.

ACCORDING to the *Cologne Gazette*, the wife of an inhabitant of Niehl has twice within eleven months been delivered of triplets.

NORTH-WEST LONDON HOSPITAL.—A Fancy Dress International Fair is to be held at the Athenæum, Camden-town, on May 3rd and two following days, in aid of the funds of the above hospital.

OLDHAM INFIRMARY.—The funds of this charity have been augmented to the extent of £1000, under the will of the late Mrs. Redfern, of Knutsford.

VACCINATION GRANT.—Mr. Durdin of Desford, Leicester, has received the Government grant for efficient vaccination in his district.

ON April 15th, Brigade Surgeon Ramsbotham and the officers of the Medical Staff at Alexandria gave a ball, which was well attended.

GUY'S HOSPITAL BIENNIAL DINNER. — The Guy's Hospital Biennial Dinner will be held early in July on the same day as the annual distribution of prizes, at which ceremony, it is hoped, H.R.H. the Duke of Cambridge will preside.

BOMBAY EYE AND EAR INFIRMARY.—At a meeting of the subscribers to this institution, held on Feb. 11th, the first report, dealing with a period of fourteen months, was presented. The number of patients who had received the benefits of the charity was 2780 for diseases of the eye, and 777 for aural diseases. The visits made by these patients were 19,109, a daily average of 54·4. The receipts amounted to 3602 rupees, and the expenditure to 2451 rupees, of which sum 825 rupees were expended in starting the institution. The hospital is open for the treatment of all persons, without distinction of caste or creed, and the committee earnestly appeal for further pecuniary support.

MEDICAL PRIZES AND SCHOLARSHIPS.—At *St. Bartholomew's Hospital* the Kirkes Gold Medal and £30 scholarship has been awarded to Mr. W. H. Hamer, B.A. At *St. Thomas's Hospital* the Mead Medal has been awarded to Mr. Samuel Walton Wheaton; the Cheselden Medal to Mr. John Herbert Tonking; the Solly Medal, and a prize in money, to Mr. Ernest Solly; and a bronze copy of the Mead Medal to Mr. Henry John Macevoy, he being distinguished by special proficiency. In the winter session prize list of the *Westminster Hospital* the Treasurer's Prize has been gained by Mr. L. Lewis; the President's Prize, by Mr. J. R. Plant; Chemistry Prize, by Mr. L. Lewis and Mr. E. J. Pritchard; Medicine Prize, Mr. H. B. Brackenbury; Surgery Prize, by Mr. C. Burt.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on April 28th, the following gentlemen were appointed Examiners for the ensuing year: — Chemistry: Professor J. Emerson Reynolds, M.D., F.R.S.; Professor T. E. Thorpe, Ph.D., F.R.S. Botany and Vegetable Physiology: Professor Bayley Balfour, M.D., D.Sc., F.R.S.; Professor F. Orpen Bower, M.A. Comparative Anatomy and Zoology: Professor E. Ray Lankester, M.A., F.R.S.; Professor Alexander Macalister, M.D., M.A., F.R.S. Practice of Medicine: Wm. H. Broadbent, M.D.; S. J. Gee, M.D. Surgery: Wm. Morrant Baker, Esq.; Professor Christopher Heath. Anatomy: Professor D. J. Cunningham, M.D., C.M., F.R.S.E.; Professor John Curnow, M.D. Physiology: Professor E. A. Schäfer, F.R.S.; Professor Gerald F. Yeo, M.D. Obstetric Medicine: F. H. Champneys, Esq., M.A., M.B.; John Williams, M.D. Materia Medica and Pharmaceutical Chemistry: J. Mitchell Bruce, M.D., M.A.; T. Lauder Brunton, M.D., D.Sc., F.R.S. Forensic Medicine: Augustus J. Pepper, Esq., M.S., M.B.; Thomas Stevenson, M.D.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ATTHILL, ROBERT C., L.R.C.P.Ed., L.F.P.S.Glas., L.S.A.Lond., has been appointed Medical Officer for the Elmstead Division of the Fifth District of the Tendring Union.

BROWNE, GEORGE HENRY, L.R.C.P.Ed., L.F.P.S.Glas., L.A.H., has been reappointed Medical Officer of Health for the Brynmawr Urban Sanitary District.

BRYANT, HENRY V., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Castor District of the Peterborough Union.

EASTON, GEORGE FREDERICK, M.D. Univ. Edin., L.R.C.S., has been appointed Medical Officer of Health for the Alnwick and Canongate Urban Sanitary District, Northumberland, vice Davidson, resigned.

FOXWELL, ARTHUR, B.A., M.B. Cantab., has been appointed Pathologist to the Birmingham Hospital for Women, vice Dr. Saundby elected Consulting Physician.

Digitized by Google

FRIZELL, THOMAS, B.A., M.D., M.Ch., L.M., R.U.I. (late House-Surgeon and House-Physician to the London Hospital), has been appointed Government Medical Officer to the Roebourne District of Western Australia.

GRIFFIN, INNES, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Banbury Urban Sanitary District, vice Grimbly, whose appointment has expired.

HODSON, FRANCIS OCTAVIUS, L.K.Q.C.P.I., has been appointed Medical Officer to the District Hospital, Government Medical Officer and Public Vaccinator for the Walgett District, New South Wales.

LAWFORD, JOHN BOWRING, F.R.C.S.Eng., has been appointed Assistant Ophthalmic Surgeon to St. Thomas's Hospital.

LAWTON, HERBERT ALFRED, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Poole Urban and Port Sanitary Districts, vice Vernede, resigned.

MACVIE, ADAM, M.D. Univ. Edin., has been appointed Medical Officer of Health for the Baildon Urban Sanitary District, Yorkshire, vice Smyth.

MONTGOMERY, SAMUEL, L.R.C.P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the Ovenden Urban Sanitary District, Yorkshire.

PAGET, CHARLES EDWARD, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Appleby Urban Sanitary District.

PARKINSON, SIDNEY G., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse of the Wimborne and Cranborne Union.

PERCIVAL, FRANK, has been appointed Assistant Medical Officer to the Lunatic Hospital, The Coppice, Nottingham.

PESKETT, A. W. CHALMERS, M.A., M.B.Cantab, has been appointed Medical Officer of Health for the Urban Sanitary Authority, Burnham, Somerset, vice D. A. Fraser, M.R.C.S., resigned.

PINKERTON, JAMES, M.D., Q.U.I., has been appointed Medical Officer for the First District of the Parish of Liverpool.

REVINGTON, GEORGE, A.B., M.B., B.Ch., has been appointed Junior Assistant Medical Officer to the Prestwich Asylum.

SHARP, EDWARD, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Truro Urban Sanitary District.

THOMSON, THEODORE, M.A.Aber., M.B.Lond., L.R.C.P. & L.R.C.S.Ed., has been appointed Medical Officer of Health for Aberdeen, vice Simpson, resigned.

TURNER, HENRY C., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the Steyning Union.

Births, Marriages, and Deaths.

BIRTHS.

CLARE.—On March 29th, at Sutton's Pasture, Vere, Jamaica, the wife of Henry L. Clare, M.B., District Medical Officer, of a son.

LANKESTER.—On the 25th ult., at Gwendwr-road, West Kensington, W., the wife of Herbert Lankester, M.B.Lond., of a son.

NISBET.—On the 16th ult., at Devonshire-road, Princes'-park, Liverpool, the wife of J. Tawse Nisbet, M.B., C.M.Ed., of a daughter.

POWER.—On the 19th ult., at Bloomsbury-square, W.C., the wife of D'Arcy Power, M.A., M.B.Oxon., F.R.C.S.Eng., of a daughter.

WELLS.—On the 22nd ult., at Belsize-park, N.W., the wife of Poulett Wells, M.B., of a son.

MARRIAGES.

ALEXANDER—FINDLAY.—On the 26th ult., at 4, Rowallan Quadrant, The Observatory, Glasgow, by the Rev. Dr. Drummond Belhaven, U.P. Church, Thomas Gray Alexander, M.B., C.M., M.R.C.S.Eng., of Glasgow, to Anna Graham, daughter of John Findlay.

HABERSHON—DAVIES.—On the 28th ult., at Menai-bridge, Anglesey, Samuel Herbert Habershon, M.B.Cantab., M.R.C.P., only son of Dr. Habershon, of Brook-street, Grosvenor-square, to Catharine, second daughter of Richard Davies, Esq., M.P., of Treborth, Bangor.

HENDERSON—BALFOUR.—On March 7th, at the Cathedral of Holy Trinity, Shanghai, Wm. A. Henderson, L.R.C.P.Ed., L.R.C.S.Ed., of Chefoo, to Jessie Elizabeth, third daughter of Joseph Balfour, of Athelstan House, Brighton, Sussex.

DEATHS.

JACKSON.—On the 24th ult., at Barnstaple, Devon, Henry Jackson, M.R.C.S., aged 35.

KENNEDY.—On the 22nd ult., at Queensberry-place, S.W., Evory Kennedy, M.D., D.L., of Belgard, Clondalkin, formerly President of the King and Queen's College of Physicians, Ireland, aged 79.

LITTLER.—On the 5th ult. (suddenly), at his residence, Embden-street, Manchester, John Watson Littler, M.R.C.S.Eng., L.S.A.Lond., the dearly-beloved husband of Mary Ann Littler, and the only son of the late Dean of Battel.

MATTHEWS.—On the 22nd ult., at Colebrooke-row, Islington, John Matthews, M.D.

ORWIN.—On the 16th ult., at Palace Chambers, Westminster (after a brief illness), Surgeon-Major Thomas William Orwin, A.M.D., eldest son of the late James Orwin, M.D., aged 47.

SEAGRAVE.—On the 23rd ult. (suddenly), at his residence Oakhurst, Sunninghill, Berks, William Seagrave, M.R.C.S., in his 71st year.

TAGGART.—On the 10th ult., at his residence, Carrickfergus, Surgeon-Major D. R. Taggart, M.D., Coroner, County Antrim and County of the Town of Carrickfergus, aged 47 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, May 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.
SOCIETY OF ARTS.—8 P.M. Dr. B. W. Richardson: Animal Mechanics (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. R. Douglas Powell will deliver the Annual Oration. At 9.15, Reception by the President and Conversazione. The Band of the Royal Artillery will be in attendance.

Tuesday, May 4.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
PATHOLOGICAL SOCIETY OF LONDON.—8 P.M. Mr. R. W. Parker: Obliterative Tracheitis and Bronchitis in Congenital Syphilis.—Dr. Hale White: Pathological Histology of Hydrophobia.—Dr. Payne: Granuloma Fungoides.—Mr. Eve: Granuloma Fungoides of Foot.—Dr. Handford: Hepatic Abscess Secondary to Pelvic Inflammation.—Dr. Norman Moore: Primary Cancer of the Thyroid.—Dr. N. Dalton: Congenital Stricture of Small Intestine.—Dr. Carrington: Double Intestinal Stricture.—Mr. Davies-Colley: Spinal Abscess destroying Right Kidney and opening into Duodenum.—Dr. Silcock: Psoas Abscess with Formation of New Bone in Sinus.—Dr. Turner: (1) Tubercular Arteritis; (2) Miliary Tubercle in Pulmonary Artery.—Dr. Mott (for Dr. Steeves): Malignant Growth of Lip, with Melanosis. A number of Specimens will also be exhibited.
SOCIETY OF ARTS.—8 P.M. Mr. Ernest Hart: Japanese Art Work.

Wednesday, May 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
SOCIETY OF ARTS.—8 P.M. Adjourned Discussion on Dr. C. Meymott Tidy's paper on The Treatment of Sewage.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Dr. Matthews Duncan: On Elasticity, Retraction, and Polarity of the Uterus.—Dr. Amand Routh: A case of Serous Perimetritis.—Dr. Champneys: On the Artificial Production of the so-called Lymphatic Varix.

Thursday, May 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Alkaloids.
SOCIETY OF ARTS.—8 P.M. Mr. Edward Coombes: The Commerce and Industries of New South Wales.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. C. M. Handfield-Jones: On Sudden Death in Pregnancy, Parturition, and the Puerperal State.—Dr. W. Ewart: On some Practical Points in Percussion and Auscultation of the Chest.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Exophthalmic Goitre, its Symptoms, Pathology, and Treatment. Communications will be made by Drs. Wilks, Bristowe, Hughlings-Jackson, Sharkey, Hill-Griffith, and Samuel West, and by Messrs. Lunn, Higgens, Silcock, &c. Living and Card Specimens at 8 P.M.

Friday, May 7.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Mr. B. H. Baden Powell: Indian Manufactures from a Practical Point of View.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn: Morbid Specimens.—Dr. Ball: A case of Multiple Warts.—Drs. Ball and Colcott Fox: Cases of Hereditary Syphilis.—Dr. Colcott Fox: Some cases of Bone Syphilis in Infants.—Dr. Scanes Spicer: A case of Chronic Cerebral Abscess following Otitis Media, with account of post-mortem examination.—Dr. Clippingdale: Educational Over-pressure of Young Children.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. Frederick Siemens: Dissociation.

Saturday, May 8.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Ernst Pauer: How to Form a Judgment on Musical Works.
SOCIETY OF ARTS.—3 P.M. Prof. George Forbes: Electricity.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

SCIENCE AND THEOLOGY.

R.L., M.D.—We do not succeed in making our position intelligible if our readers are unable to understand that we protest against the affirmation of neology; on the obvious ground that nothing positive can be based on a negative. It is absurdly illogical to assert that there cannot be a soul or a future state simply because the investigations of biologists have not resulted in the discovery of either. The scientist, *as such*, must be agnostic in the sense of knowing nothing of a soul or a future; but he has no reasonable ground for denying their existence. He simply does not know. He may go so far as to say these things are unknown: but he has no right to declare that they are unknowable, much less can he deny their existence. So far as he is concerned, there may be a soul and a future, and religion may be true. As a *scientist*, he has simply nothing to do with the subject. As a *man*, he is free to believe or disbelieve what he pleases. This being our view, it would be inconsistent for us to join issue with the materialist, or to attempt to bring science to the aid of religion. The time has not arrived—whether it ever will or not we have no means of judging—when there shall be a science of religion. At present the subject matter of religion is, in a scientific sense, unknown. There are, however, in all times and places those who worship "the Unknown."

L. H. Masser.—The office is at 27, Chancery-lane, where information may be obtained.

Dr. Wiglesworth (Rainhill).—Yes, in an early number.

TENDER FEET.

To the Editor of THE LANCET.

SIR,—In reply to "X" in your last issue (p. 815), will you allow me to say that I can fully sympathise with your correspondents, having been for many years a sufferer from tender feet, for which the easiest of boots afforded no relief. It occurred to me that the complaint might be due to some low form of vegetation affecting the skin, derived perhaps from the leather of the boots. Acting on this theory I was led to try the remedy used at the Cape for destroying the fungus (oïdium albicans) affecting the cuticle of the vine leaves. I dusted the feet with sulphur, and found immediate relief, but the remedy was attended with inconvenience. I afterwards tried the simplest of antiseptics—common salt,—and found it to answer perfectly. The plan I follow is, after the morning bath, to sponge the feet with a strong solution of salt (three tablespoonfuls to half a pint of water), afterwards drying lightly.

I am, Sir, yours truly,

April 29th, 1886. CAPENSIS.

GAOLS IN GEORGIA, U.S.A.

JUDGE JOEL BRANHAM of Georgia has been reading the State authorities a salutary lesson on the hygienic treatment of prisoners, as the following speech will show:—"A great many of the county gaols in Georgia are a disgrace to our civilisation. They are built with no reference whatever to the comfort of those who may be compelled to occupy them, while from a sanitary point of view they are often hardly fit to be occupied by animals, let alone human beings. With few exceptions, they are not furnished with the means of ventilation, and the bad air which the prisoners are compelled to breathe often breeds diseases. Then, again, many of them have no provision for being warmed in cold weather, and much suffering has resulted from this cause during the past winter. The law does not seek to punish a man by freezing him or depriving him of pure air. For this reason, I have made it a point to charge the grand juries wherever I held court to carefully investigate the gaols, and see that they are furnished with proper heating apparatus and the means of ventilation. There should certainly be some State supervision over all prisons, both county and municipal. I have long advocated the appointment of an inspector of such prisons, with plenary powers to enforce all laws pertaining to them."

M.R.C.S.—Our correspondent's experience will no doubt be a warning to him not to attend and give evidence at an inquest without a subpœna duly served. For all that, we maintain that when a coroner asks, through his constable, a medical man to attend an inquest, he is morally bound to tell him that he cannot pay a fee, or, failing such notice, to pay it. We advise our correspondent to lay the facts before the Home Secretary. He owes this as a duty to himself and to the profession.

Physician has not enclosed his card.

SIX MONTHS' EXPERIENCE OF SANITARY WOOLLEN CLOTHING AND BEDDING.

To the Editor of THE LANCET.

SIR,—I should be glad if you can give me the opportunity to render to your readers a short account of the effects in my experience of the use of sanitary woollen clothing and bedding. If I may judge from my own case very many who may have read or heard more or less of Dr. Gustav Jaeger's propositions with regard to dress have dismissed them with little ceremony as pedantic or as well enough for those who are not acquainted with the virtues of good English underclothing, &c. To all such I would say "Don't." The experience of several winters led me to look forward to the last with grave apprehension as prolific of severe and exhausting catarrhs, followed by increased susceptibility and renewed attacks. In October, I, for the first time, saw an exposition of Dr. Jaeger's views in his excellent little volume "Health Culture," and was so impressed with their soundness that I adopted the sanitary woollen clothing and bedding advocated by him in their entirety. The result has been complete immunity from colds and a very marked increase in my capacity for work. I have not put on a great-coat night or day, have slept with an open window in bedroom, and have been able to enjoy the luxury of an open cab instead of a close brougham. Instead of alternating feelings of heat and cold, there has been a uniform and most agreeable glow of warmth. I have, without any alteration of diet or regimen, lost 7 lb. in weight, and (which will, I believe, tax the credulity of some) have witnessed the disappearance of a lipoma of the nape of the neck, which had existed for some years, and had suggested the necessity for an operation. These latter facts powerfully illustrate the truth of Dr. Jaeger's contention that the complete and continuous action of the skin drains the organism of water and superfluous fat. I would say, further, that the feeling induced of perfect health is not the least of the recommendations to adopt the system. I may mention that of the many who have, more or less, fully addicted themselves to it from my example or advice I have not known one who has been disappointed. Lastly, I would add a word on the need there is, if the full benefit to be derived is wished for, that nothing but pure wool should enter either into dress or bedding.

I am, Sir, yours faithfully,

JOHN PENHALL, M.D., F.R.C.S.

St. Leonards-on-Sea, April 17th, 1886.

Inquirer.—1. The public vaccinators are paid at a certain rate for each successful case by the boards of guardians. The minimum fee is eighteenpence for every vaccination done at an appointed station situated at or within a mile from the residence of the vaccinator or in the workhouse of the union or parish; not less than two shillings for every vaccination done at any station over a mile and under two miles distant from his residence; and not less than three shillings if the station be distant over two miles. It should be noted that these are minimum fees, and that the guardians are permitted to pay more. It is right therefore that the public vaccinator should be properly remunerated, and when he can obtain better terms he should do so.—2. Public vaccinators are appointed by the boards of guardians, subject to the approval of the Local Government Board.—3. The Government grant for efficient vaccination is a maximum fee of one shilling for each successful case.

Dr. Auld (Wick).—Yes; as early as possible.

VENANZIO LUPACCHINI.

"LA cura della Idrofobia e la Scoperta di Pasteur"—such is the title of a paper in the *Nuova Antologia* of April 1st, which may be recommended as perhaps the most succinct, while most exhaustive, account of the malady and of previous attempts to cure it yet given to the public. The author is the distinguished physiologist, Signor E. Mancini. Italy, indeed, has special reason to study, and to try to find a remedy for, hydrophobia, if only for its having cost her so many valuable lives, of which few have been more valuable than Lupacchini's. That brilliant physician, classical scholar, and mathematician, to whom the text of Celsus owes so many felicitous emendations, met his death from the bite of a dog under circumstances so remarkable as to deserve recapitulation. On June 14th, 1774, when in his forty-fifth year, a favourite spaniel bit him on the back of the left hand and on the external malleolus of the left foot. Having treated the wounds as seemed best at the time, they caused him so little inconvenience or mental disturbance that he ceased to think of them, being fully persuaded that the dog was not mad. A year passed, and still there was nothing to arouse suspicion. But in the July of 1775 he began to complain of a certain torpor in the left side, and this he treated with the bath, but not so successfully as to conquer the disquieting sensations. The malady first declared itself as hydrophobia in the month of August; but the symptoms once more disappeared until the last day of September. Again the bath was resorted to, and, by way of gratifying his anxious friends, he went to the sanctuary of San Domenico a Cucullo, celebrated throughout his native Abruzzi for the cures it wrought on the faithful. But on the way to this shrine he was overtaken by most violent hydrophobic convulsions, so that he had to alight at Aquila, where the malady continued to declare itself more and more till the night of October 22nd, 1775, when a final, agonising convulsion put an end to his torments. Medical scholarship was thus deprived of a most useful and brilliant light, in one who has not inaptly been described as "an eighteenth century Littre."

Mr. J. S. Dunlop.—We do not quite see what is meant by the term "Medical Assurance Companies."

INFANT FEEDING: COD-LIVER OIL.

To the Editor of THE LANCET.

SIR,—In reference to the annotation on infant feeding which appeared in your issue of April 17th (p. 756), permit me to suggest a mode which I have adopted for many years with unfailing success—I allude to the addition of cod-liver oil to the food of hand-fed infants. Swiss milk is one of the best substitutes for mother's milk, and many infants thrive upon it remarkably well. But we constantly meet with cases in which no kind of artificial food is of benefit, and the poor little creatures waste away, many of them dying of sheer inanition. Now, in these cases cod-liver oil comes in with admirable effect. It is most conveniently given in this way:—Let the nurse dip the end of her little finger in the oil, and put it into the child's mouth. This may be repeated five or six times in the twenty-four hours. In such small quantities, not only does it never disagree, but the child sucks it off the finger with avidity and evident pleasure. It may be administered in this way to the youngest infants. By this simple and inexpensive expedient I have seen many infants who were absolutely starving for want of the natural foods become fat and plump and happy in an almost incredibly short space of time. The oil has the effect of enabling the child to digest other food, which it could not retain on its stomach without it. The great mistake in hand-feeding is to resort, as is commonly done, to preparations of vegetable production which are not suited to the organisation of infants, who are clearly intended to live on animal food; and if that provided by nature, in the form of mother's milk, cannot be given, then the milk of some other animal should be substituted, perhaps with the addition of a little gelatine. But with the aid of cod-liver oil, as I have suggested, any good pure milk will agree with and nourish the child.

I am, Sir, yours obediently,

London, April 26th, 1886. S. YELDHAM, L.R.C.P.Ed., M.R.C.S.

Vigilans.—In a circular of a hydropathic institution we notice that medical men are offered £1 a month for patients recommended by them, and who stay not less than one month, and £2 if they stay three months or longer. We think that this is objectionable. Medical men in advising places of change to their patients are supposed to be acting on purely professional considerations. This supposition would be marred if any commercial considerations were introduced into the question.

F.R.C.S.Eng. (exam.) has omitted to enclose his card.

"KISSING THE BOOK."

To the Editor of THE LANCET.

SIR,—I think we might with advantage take a leaf out of our American cousins' book. I was called upon to give evidence in an American court of law, and when the oath was administered I had to lift up my right hand.

I am, Sir, yours truly,

Sierra Madre, March 31st, 1886. F. C. GRESHAM, M.D., M.R.C.S.

Digitized by Google

THE BARTLETT CASE.

WE have received a letter from *Mr. T. L. Nichols*, M.D. Univ. New York, U.S.A., the author of "Esoteric Anthropology," enclosing an "Appeal for Justice" against the opinion expressed by Mr. Justice Wills on the character of the book in question. But it is obviously impossible for us to insert strictures on the comments of a judge (even if we differed from him) written at the length and in the strong terms of the appeal.

Thames.—If the election is annual, or the present holder of the appointment vacates it, by death or otherwise, our correspondent's candidature must be successful, if proper representation be made to the Central Board.

Mr. J. G. V. West.—Short notes of the case would be acceptable.

PNEUMONIA AMONGST SOLDIERS.

To the Editor of THE LANCET.

SIR,—Will you allow me to call the attention of the military authorities to the desirability of the soldiers on guard wearing their great-coats when on sentry? I have frequently noticed them with only the tunic, the bitterest east wind blowing hard all the while, and I dare say their under-vests are not at all too warm to protect them against the severity of the weather. Would not this in a great measure account for the "unusually heavy mortality (chiefly chest complaints) amongst the younger soldiers," as recorded? I am, Sir, yours faithfully,

April 24th, 1886. A SANITARIAN.

Enquirer.—We think that the particulars should be given if asked for, if it is intended to press the claim legally.

Enquirens.—Parkes or Wilson.

HOODED GIG OR BUGGY.

To the Editor of THE LANCET.

SIR,—Will any country practitioner who has habitually used a hooded gig or buggy give me the benefit of his experience as regards its comfort in driving long distances on hilly roads—as to whether the occupants are fairly well protected from bad weather, and as to whether any inconvenience is experienced in driving against a head wind when the hood is up? Such information would be thankfully received by

Yours faithfully,

April 26th, 1886. A COUNTRY DOCTOR.

Alpha.—We know of no systematic account of the post-mortem appearances in cases of persons dying from eating poisonous or tainted fish. In some instances nothing abnormal has been discovered, and in most, we imagine, nothing more would be seen than the effects of an irritant. The symptoms generally point more to a toxic agent than to a fatally irritant one.

S.B. is referred to the Medical Directory.

CORRIGENDA.—In the fifth line of the first paragraph of Mr. Eyles' Note on Malarial Icterus and Hæmoglobinuria, in our issue of Jan. 30th, for "spasm" read *plasma*; and in the sixth line of the fourth paragraph, for "hæmoglobinuria" read *hæmoglobinæmia*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Brailey, London; Prof. Latham, Cambridge; Dr. Savage, London; Sir R. N. Fowler, London; Mr. Vincent Jackson, Wolverhampton; Mr. Godlee, London; Dr. Whitson, Glasgow; Mr. Jalland, York; Dr. Charteris, Glasgow; Dr. H. V. Carter, Bombay; Dr. Hellier, Leeds; Mr. Percy Dunn, London; Dr. Tucker Wise, London; Mr. T. L. Phipson, London; Mr. A. Wright, Romford; Mr. F. Vacher, Birkenhead; Dr. Sutton, Sittingbourne; Messrs. Slazenger and Sons, London; Mr. Eyles, Gold Coast; Mr. J. Robertson, Edinburgh; Dr. Lewins, London; Dr. T. L. Nichols, London; Mr. Haslam, Birmingham; Messrs. ABSTRACTS OF THE

Lumleian Lectures

ON THE

ELECTRICAL CONDITIONS OF THE HUMAN BODY.

By WILLIAM H. STONE, M.A., F.R.C.P.

LECTURE III.

DR. STONE said that in the second lecture he had shown the effects of polarisation which occur in all electrolytes and in the human body to an extent not previously measured, as far as he knew. The important bearing of polarisation on electrotonos was also discussed. He had to make two corrections. In the skeleton form of Mance's method a minus was omitted between the two terms of the numerator A – B. This he believed led him to describe the formula as one of multiplication. "The product divided by the sum" was so familiar to electrical workers that the mistake was natural. The method really used was the difference of the compound quantities designated A or B divided by that called C. Dr. Ord also suggested that he had not made the demonstration of the two sounds in the induction discharge quite clear on the telephone. This experiment was therefore repeated in another way.

Coming to the subject of the third lecture proper, Dr. Stone said the account of induced currents was in every text-book. Induced currents are momentary, occur at make and break; the current in the primary coil induces also an extra current in the opposite direction, which therefore weakens the effect of make, whereas on breaking the opposite effect takes place. Induced currents came early into physiological and therapeutical use because of their obvious effect on the sensory nerves, of their action on muscle as a stimulant, and on account of the remarkable work done by Duchenne. Duchenne used a clumsy and primitive induction coil, though he accomplished a vast amount of work, and isolated several new nervous diseases, by testing the reactions of muscles to stimulants. But his coil was merely a convenient stimulus—it had no electrical value. For testing the contractility of muscle it is still unequalled. It is also most valuable as a means of keeping up the irritability of muscle which has been damaged by the metallic impregnation of lead, or from which, by nerve injury or more deep-seated lesion, motor nerve influence has been cut off. This induction coil is really a muscle stimulant, and very little more. It may also be used, though with more caution, to test sensation. Here, however, individual differences of temperament step in, the tolerance to induced currents being extremely various in different persons. At fairs and market gatherings the "try your strength" devotees of electricity merely test the individual's capacity to stand a particular amount of induced current. This form of electricity may do good service in stimulating ever so deep-seated a muscle as the diaphragm in asphyxia or suspended animation. In the lecture-room, too, it is most convenient and effective for physiological demonstration. But here its use should end. At present, as a means of physiological research, it is unsafe. The lecturer much regretted that some recent researches as to localisation of cerebral function had been founded on the use of induction currents. There is not only no proof that the current passes through the region included between the poles, but there is conclusive reason to believe that it diffuses itself widely and irregularly in all directions, with enormous differences of density. Further, it is doubtful if it ever traverses a moist substance like brain tissue at all, or only starts a series of laminated polarities something like a condenser. In a feeble conductor a polarised state is set up which is the very reverse of transmission of current. There are, however, two very different kinds: induced and alternating currents. The latter obtained from a commutator and battery are the best. It has been asserted in a medical journal that it is impossible to measure induced currents. But this is not true. They may be measured by three methods: (1) Kohlrausch's dynamometer, in which the moving needle of the galvanometer is replaced by a moving coil; (2) Dr. Stone's instrument with a very light aluminium coil, this metal being the largest known conductor of electricity; and (3) A modification of this, a simpler form, in which two sheets of ordinary very soft annealed iron are employed; they rapidly change their polarity, and may be regarded as part and parcel of the circuit going to them. He believed that this would prove the dynamometer of the future for medical purposes. The induced currents could also be measured by the quadrant electrometer with which Professor Stocker and Mr. Gregory had made determinations. The lecturer next showed Kohlrausch's combined induction coil and meter bridge, with telephones used as galvanometers. He showed that with induced currents the resistance came out different from that obtained by the constant current, being about one-half to two-thirds of that observed with the latter. Thus the resistance of the St. Thomas's Hospital porter was found to be 600 ohms as compared with the 1160 of the constant current. The telephone became silent when 600 ohms had been introduced to balance the resistance given by the porter. Now this, though it renders this elegant method untrustworthy for the measurement of resistance, is a physiological fact of considerable importance. It is susceptible of several explanations: 1. The human body, like all imperfect conductors, is really probably more permeable to high tension than to low tension currents. Indeed, Dr. Stone considered that his experiments fairly demonstrated this. 2. It is probable that, with rapid intermission, the current does not really pass at all, or not fully until it is annulled by the next current in the opposite direction. The human body under the circumstances would be like the leaves of a book in a stratified or laminated state; or, more closely, like an elastic body transmitting the waves of sound, with alternate phases of condensation and rarefaction, represented in this case by positive and negative polarities. The same argument was illustrated by the early experiments of Du Moncel. 3. An alternating current ought to show too low a resistance, as Dr. Oliver Lodge has suggested to Dr. Stone, because of its electrochemical capacity, which it would treat like conductivity. If we were to measure the resistance of a perfect condenser it would not come out infinite, even if the insulation were perfect. The second and third headings of explanations gave Dr. Stone grounds for believing that the body had a condenser action. 4. There is probably considerable self-induction. The possibility of this playing a part was brought out very strongly before the lecturer by Professor Hughes's highly suggestive paper read before a meeting of the Society of Telegraph Engineers.[1] There is still some controversy as to the mathematical interpretation of his facts, but the lecturer himself believed that in the main the facts point to a new direction of research which may be utilised by physiologists. Mr. Hughes divides the current into stable and variable periods. The continuous current is stable; the alternated or interrupted, variable. It is with the latter that induction takes place. Instead of the time-honoured hammer of the induction coil, Professor Hughes employs his own invention, the microphone, or, better, a small contact-breaking clock. This enables the ordinary meter bridge to be used for measuring resistance. [A successful experiment was then made with the hospital porter.] Or this method may be combined with Professor Hughes's sonometer. Dr. Stone showed a simpler form in which the induction coil slides along a bar. [Another successful experiment was here performed.] If these coils be set up at measured distances, and an interrupted current passed through the primary coil, the living human body, and a known resistance in the secondary circuit, on either side of the telephone good measures can be obtained. It is a question of balance; when the currents in the two circuits are exactly equal the telephone is silenced. By this means the resistance in the human body can be measured. But there is a still further modification of the instrument which Dr. Stone exhibited and explained, though he had not yet had the opportunity of taking any measurements therewith. This modification is also due to Professor Hughes, and is a most ingenious combination of the meter bridge with the sonometer. By its aid the lecturer hoped to balance resistance in the body and self-induction of the body independently; up to the present, however, no certain results had been obtained.

General considerations.—There is a vast field open for

[1] Electrician, Feb. 5th, 1886, p. 127.

Digitized by Google

research; indeed, the whole basis of physiological electricity requires strengthening and re-examining. It is a stately building of which the foundations are unsafe, and until these are made firm the whole superstructure is in danger. If, on the other hand, it be done, we shall in the course of the necessary explorations come on many precious discoveries. Already the analogies between nerve force and this great physical force are becoming strong. One such on inhibition was published in *Nature* by Dr. Lauder Brunton. There were many analogies also between the duplex submarine cable and nerves; the indications in both were made at the far end, and nothing occurred at the near end. Dr. Stone urged that nature must have worked on one plan. He was disposed to believe that there was a real analogy between the cable and the nervous system. Many were the hopeful directions for electrical work—its therapeutic use in muscular enfeeblement, lead paralysis, cases of neuralgia, locomotor ataxy, and progressive muscular atrophy. He believed, also, it proved of service in loosening chemical compounds administered by the mouth; the metals were set free from their salts—mercury, arsenic, zinc, and silver. It possessed also a decided eliminative action; he himself had collected three milligrammes of copper from the urine of one patient. Colonel Bolton, a well-known and trustworthy advocate of electricity in therapeutics, also regarded it as a hypnotic; whilst, again, its influence on the vaso-motor system was amongst its most well-known effects.

Clinical Lectures on DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary.

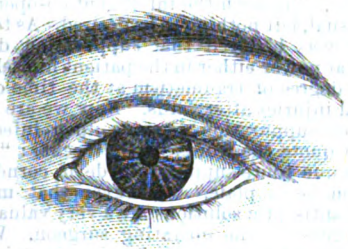
By CHARLES BELL TAYLOR, M.D., F.R.C.S.,
SURGEON TO THE INFIRMARY.

LECTURE II.

GENTLEMEN,—The female patient you have just seen is sixty-five years of age, blind from cataract in both eyes, and exceedingly deaf. The male patient is a labouring man, toil-worn, weather-beaten, and seventy-five years of age. He has been blind some months from cataract in the left eye, and the right is dim, although he can still see to go about with it. I saw these patients for the first time this evening, and propose to operate at once, using artificial light; before doing so, however, permit me to comment upon several questions which have arisen in connexion with these and other similar cases.

What is cataract? Cataract is an opacity of the lens. How is it that so many aged persons suffer from cataract? Well, I suppose we must look upon cataract in aged persons as one of the natural phenomena of life—the culminating point in that process of hardening, shrinking, and degeneration which the lens undergoes in common with other tissues as we grow older, and which seems natural to us all. When, for example, an average individual attains the age of forty and upwards, he requires glasses. Why is this? Simply because the lens has become too hard to fulfil its usual function in the process of accommodation for near objects. As time passes on, this—shall I call it natural sclerosis?—increases, until in certain cases the normal relationship of the lens fibres is so changed that it becomes opaque; the patient cannot see, and the surgeon cannot illuminate the fundus of the eyeball: that is cataract. The lens has become opaque, and, so far from assisting vision, constitutes an actual obstruction to the passage of the rays of light. Would it be possible to restore the transparency of the lens? What a momentous question! As well ask would it be possible to restore youth. And yet there is no doubt that by judicious treatment the progress of senile cataract may be retarded. I have seen benefit from electricity, and quite marvellous results, in certain cases caused by accident, or complicated with gout, diabetes, and albuminuria. In both these patients, however, the lens is quite opaque—the cataract is fully formed. There is no possibility of any clearing up. The obstruction must be removed, and this can only be done by operation. What operation shall we perform? Will any surgical procedure short of actual removal of the lens from the organism—that is extraction, as it is called—suffice? I fear not. If we attempted in either of these cases to disintegrate, macerate, and dissolve the lens *in situ* by repeated needle operations, we should in all probability only excite iritis, to which aged persons are especially liable. Very likely the inflammation would prove uncontrollable, and we should be driven to extract at last under far more unfavourable conditions than exist at present. Would it be wise, in obedience to the ancient precept, "Squamam in oculis emovendam potius quam extrahendam," to attempt to depress the lens, dislodge it from the axis of vision, and thus permit the reproduction of images upon the retina? I do not think so. The lens is apt to rise again, or act with all the pernicious influence of a foreign body in the vitreous chamber; so that, although I am not at all disposed to deny that such an operation may be occasionally successful, the risk is too great, and I should not dream of attempting it in either of these cases.[1]

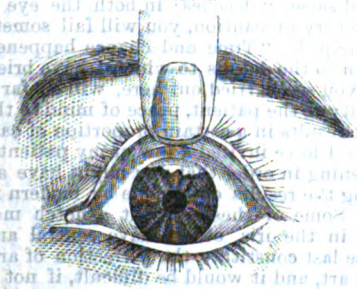
It is clear, therefore, gentlemen, that our only resource is extraction. What is the best method of performing extraction? In order that you may appreciate this question it will be necessary to glance at the history of the operation, which may be said to have commenced in 1752, for although, as the quotation from Pliny just cited proves, there can be no doubt that a method of extraction was known to the ancients, it was not until that date, when Daviel presented his classic memoir to the French Academy, "Sur une nouvelle Méthode de guérir la Cataract par l'Extraction," that the actual removal of the lens from the eyeball assumed its proper place as a recognised operation in contemporary surgery. Daviel operated while seated himself and facing his patient, who also occupied a chair on a lower level. He used a lance-shaped knife, and incised the lower half of the circumference of the cornea, delivering the lens through the natural pupil. When successful, the flap operation, as it is called, left nothing to be desired; but fifteen eyes in a hundred were irrevocably lost, and twenty more so damaged that it is a matter for special wonder that no serious attempt at improvement was made until 1860, when Herr von Graefe, the celebrated professor of Berlin, announced, as the result of the daily examination of eyes recently operated on, that the part of the eyeball which took the initiative in the destructive inflammatory process was the portion of iris contused during the exit of the lens, and that this stretching and bruising was consequently the *teterrima causa* of subsequent disaster and loss of sight. Acting on this hint, Mooren, of Dusseldorf, excised the piece of iris corresponding to the flap some weeks before extracting; and Schufte, at that time Von Graefe's assistant, seeing the small proportion of eyes lost after iridectomy—about one in five hundred—simply performed that operation in the ordinary way, and then scooped out the lens with a spoon. Shortly afterwards Graefe published his famous memoir on linear extraction, placing the wound in the plane of the lens entirely outside the cornea. Jacobson, of Kœnigsberg, and Pagenstecher, of Wiesbaden, followed with similar sclerotic incisions both upwards and downwards, the latter removing the lens with its capsule entire by means of a large spoon. I visited Graefe's, Pagenstecher's, and Mooren's cliniques at this time in order to study their various methods of operating, and, after careful investigation of the whole subject, arrived at the conclusion that Schufte's incision in the corneal margin was the best, and that it needed but to be slightly enlarged in order to enable us to extract the lens without the objectionable scoop or the use of any traction instrument whatever. After operating in this way with most brilliant success upon a number of cases with an incision combined with an iridectomy, and comprising only one-third of the upper segment of the cornea, I published an account of the procedure in the *Ophthalmic Review* and *Edinburgh Medical Journal*, and it has since been universally adopted as the operation *par excellence* for cataract by ophthalmic surgeons both at home and abroad. They call it a "modified Graefe," but it is really the operation I described



[1] In illustration of the occasional success attending depression, I may remark that some years ago I extracted cataracts from both eyes for an eminent practitioner of medicine, who had so successfully operated by couching, as he termed it, upon his own brother (a clergyman) that his patient was able to resume his duties as rector of a large parish.

Digitized by Google

at that time, Graefe's original method having been so completely abandoned that it is now popularly said that nothing remains of it but the knife. I have also endeavoured in certain cases to preserve the pupil, while securing at the same time the advantages of an iridectomy, by excising only the periphery of the iris, leaving the sphincter untouched and free in the anterior chamber—an operation which possesses many advantages both optical and æsthetic, but which is rather difficult to perform. I have here a patient, a lady seventy-five years of age, on whom I operated last week in this way. When the upper lid is in its natural position, the eye, as you see, looks perfect (see Fig. 1); but when the lid is raised the coloboma in the periphery of the iris is revealed (see Fig. 2).



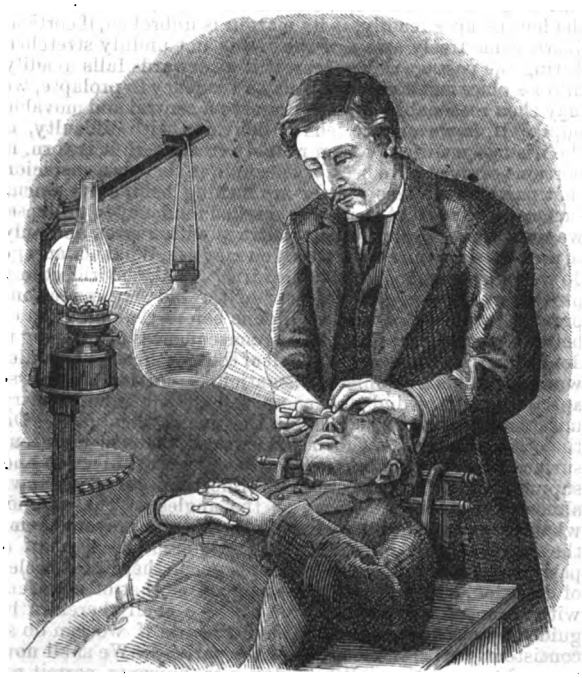
Let us see now, gentlemen, *en résumé*, what the last twenty years have done for us. Graefe discovers, or thinks he discovers, that the bruised iris is the sole cause of disaster;

FIG. 1.

Mooren cuts the Gordian knot by excising the portion likely to be injured; Schufte follows with iridectomy scoop and small incision; Graefe adopts a linear incision entirely outside the cornea; I propose a small flap in the corneo-sclerotic junction; other distinguished operators place their incision entirely in the cornea. Have we arrived at the *ne plus ultra* of ophthalmic surgery? Must we rest and be thankful, or shall we go back and make a selection from the labours of our distinguished *confrères*, adopting some of their suggestions and rejecting others? Well, it seems clear that modern surgeons are right in abandoning Graefe's linear extraction. The wound is too far back; the danger of prolapse of the vitreous is too great. A vast iridectomy is necessary in order to prevent strangulation of the iris at the angles of the wound. There is great risk of bleeding into the anterior chamber in the early stage of the operation—a most embarrassing complication; and the site of the wound is such as to excite well-grounded fears of sympathetic

FIG. 2.

ophthalmia; moreover, the best results will not bear comparison with those obtainable by flap extraction. The division of the operation into two parts, as in Mooren's method, is so manifestly objectionable, that it is clear that this operation must be reserved for those cases in which it is necessary to perform iridectomy as a preliminary on account of glaucomatous or other complications. The profound anæsthesia insisted upon by Jacobson before operating renders his method too dangerous for general adoption, and the traumatism and frequent loss of vitreous attending the use of Pagenstecher's spoon will preclude its general use. As to Liebreich's, Lebrun's, and Warlomont's modification of Kuchler's transverse incision of the horizontal meridian of the cornea, these operations all, especially when the lower section is adopted, cause a certain amount of subsequent astigmatism, which prevents our obtaining the best visual results; and the operation I have spoken of as my own, though it appears to me as perfect as any combined method can be, involves, like all the rest, a mutilation of the iris, which leaves much to be desired, and, inasmuch as it is not always necessary, will certainly never be adopted to the absolute exclusion of other methods by which the pupil is preserved entire.



We must always aim, gentlemen, at the highest, and the highest indication of success in cataract operations is a central and movable pupil; we may not be able to secure this in every case or even in a very large proportion, but we ought in a certain percentage, and in order to do so we must adopt what the late Mr. Critchett denominated a method of eclecticism. We must enlarge the wound to four millimetres, or more if necessary; we must bring it forward in the cornea, or place it back in the sclerotic junction, according to circumstances. We must select, not our patients, but our operations, and be guided by each step of the operation what the next step shall be. For instance, I have been asked whether I intended to perform iridectomy in either of the cases now before us. Well, I cannot answer that question at present; the reply in each case must depend on the conduct of the patient, the peculiar nature of the affection, and the size and consistence of the cataract as revealed upon the operating table. If either of our patients should prove as indocile and as utterly wanting in self-control as the deaf man on whom some of you saw me operate last week, I shall be compelled to excise a portion of iris in order to prevent prolapse. If, on the contrary, the patient gives evidence of a certain amount of self-control, if the lens escapes readily, if its margin is unbroken, if cortical débris come freely away, if the iris is not unduly stretched during the passage of the lens, if it afterwards falls readily into its place and does not display a tendency to prolapse, we may then reasonably hope to preserve a central and movable pupil. If, however, the lens is delivered with difficulty, if the iris has manifestly been roughly treated, if it is torn, if portions of uvea have been brushed off, if there is a suspicion that particles of lens matter are lurking behind its uncut surface—above all, if it shows a marked tendency to prolapse, we must excise a portion, but always with regret and only to prevent subsequent disaster. You may ask, What advantage do we get by excising a portion of iris? Well, the iridectomy prevents prolapse—that bugbear of the old flap operation; prevents bruising of the iris if done before the operation or before the exit of the lens, and the consequences of bruising if done after; permits more easy exit of the lens through a smaller wound, and also complete evacuation of cortical débris, so apt to be left behind and cause subsequent inflammatory mischief when concealed behind the uncut membrane. On the other hand, when the iris is excised there is more cut surface, more wound exposed to the danger of infection and suppuration. The dissection of iridectomised eyes shows almost invariably adhesions at the angles of the wound, whatever precautions may have been taken to prevent them; the eye is visibly mutilated; and although the sight of a patient with an upward coloboma is good, there are circles of diffusion, and it is not quite as good as that of a patient with a central and movable pupil. We shall therefore be guided by circumstances, and save the iris if we can do so consistently with the security of the patient. We shall now proceed to operation. Before doing so, however, permit me to call your attention to the method of illumination which I always use at this time of year. The light is obtained from an ordinary paraffin lamp, and the rays are concentrated by a lens in the shape of a globe of water—a simple apparatus, which may be used without preparation in any cottage or private house, an ordinary water-bottle held by an assistant sufficing for the lens. (Fig. 3.)

Remarks after operation.—I do not know, gentlemen, whether you are aware of the fact, but statistics tell us that a preponderating fatality has always attended operations for cataract upon the left eye. This is doubtless due to the greater difficulty of operating upon the left eye, a difficulty which I have endeavoured to obviate by using a bent knife, which I devised some years ago, and which you noticed, although the left eye was selected for operation, was, in the case of the male patient, held in the right hand. With this knife I would rather operate upon the left eye than upon the right, since the natural tendency of the eyeball to roll inwards, to be pushed before the knife, is in your favour if the left eye is selected for operation, and against you if the right is the subject of extraction. As those of you who were near enough to see remarked, the iris in this case persistently prolapsed after removal of the lens, and I was therefore compelled to excise a portion for safety's sake. With this excep-

Digitized by Google

tion the operation was completed without misadventure. In the female patient, the tendency of the iris to fold over the edge of the blade of the knife was, as you noticed, evaded by a *tour de main*, and the wound so managed as to form a small flap situated in the upper segment of the corneo-sclerotic junction; the capsule was then punctured, the lens extruded, and the operation completed, leaving, in this case, a central and circular pupil. I shall speak directly as to the local anæsthetic which was used and the antiseptic precautions which were adopted throughout; before doing so, however, permit me to answer one or two questions which have been addressed to me. I have been asked whether the male patient's great age did not contra-indicate operation? whether the patients would not have been better for some preliminary treatment? and whether it would not have been desirable to have administered some general anæsthetic? I will reply to these questions *seriatim*, and first with regard to age. Age *per se* is certainly no contra-indication. Cataract is a disease of old age, and if we did not extract for patients advanced in life we should not operate at all. I was once called to see a gentleman suffering from cataract in his eightieth year, and strongly recommended operation; his wife, however, would not allow him to submit, on account, as she said, of "his great age." Six years later she died; the widower then sent for me, was operated on, and

FIG. 3.

recovered most excellent sight—so good that he was able to complete an archæological work on which he was engaged when his sight first failed. I have operated with perfect success upon both eyes in a patient over ninety, and upon a considerable number between eighty and ninety years of age. Lord Lyndhurst, the then Nestor of the House of Commons, was operated upon in his ninetieth year. The first eye was lost, but, with characteristic courage, he underwent the operation again and recovered excellent sight with the second eye. In fact, the hard senile cataract is more readily extracted than the less mature varieties of the same affection; and although persons of great age are generally very feeble and suffer from various senile affections, this, so far as my experience goes in hundreds of cases, does not seem to interfere very materially with the success of the operation. As to preliminary treatment, no doubt it is of the utmost importance that patients undergoing operation should be in a fair state of health. No doubt preparatory treatment similar to that adopted in the training of athletes would increase our chances of success if it were possible to carry it out, but experience teaches us that directions of this kind are never carried out at home, and admission to hospital only has a depressing effect. So that I think that the advice to persons about to be operated on may be summed up in two lines:

"Great temperance, open air,
Easy labour, little care."

You cannot train old people; and beyond this it is difficult to go. With regard to anæsthetics, when I commenced practice it was the custom to use chloroform in almost every case; subsequently ether was very generally employed; but for years past I have operated without any anæsthetic, and but for the splendid discovery of cocaine should have continued to do so. Chloroform I found from time to time gave rise to most distressing symptoms of impending dissolution. Ether caused great excitement. Both were followed by dangerous vomiting, and although the latter is incomparably safer than chloroform, the drunken violence both before and after is more dangerous, and I have known it on three occasions to provoke attacks of bronchitis, one of which proved fatal. Cocaine was employed in the cases we are now discussing, and its effect in numbing sensation, without interfering with the intelligent co-operation of the patient, as usual, left nothing to be desired. As to antiseptics, formerly it was believed that suppuration depended on deficient vital power either in the patient himself or the part injured, the degree of traumatism at the time of operation, or accidental injuries afterwards. Now we are assured that every case of suppuration depends upon infection of the wound. To quote the words of De Wecker: "Aujourd'hui nous savons que toute suppuration de la cornée est due à une infection de la plaie." However that may be, it is certain that antiseptic solutions are a very valuable addition to the resources of the operating surgeon. What is the best antiseptic to use? Well, bearing in mind the most important of all maxims in surgery, "Primum non nocere," I think you will find for general use a saturated solution of boracic acid the best. If you wish to be specially safe against microbes and macrobes, the same solution containing the twenty thousandth part of a grain of corrosive sublimate may be employed. As to after-treatment—if the slight pain which the patient experiences as the effect of the cocaine goes off does not pass away, but increases, bleed, inject morphia, and apply cold compresses; if suppuration threatens, use hot aromatic fomentations, with pressure bandages and throughout antiseptic dressings. Von Graefe objected to local bleeding for the first three days after extraction—I hardly know why; but when I attended his clinique in Berlin he strongly advised the students to avoid local bleeding for the first three days after extraction, preferring to take blood from the arm. In any way, whatever you do, you must kill the pain. *Obsta principiis*—stop the beginning, and before it begins if possible. I have taken twelve ounces of blood from the temple with the artificial leech myself in one case, and in another used seventy leeches; in both the eye was saved. In spite of every precaution, you will fail sometimes; that cannot be helped. "Time and chance happeneth to all"; but attention to the details to which I have briefly alluded, and which you see carried out here, will so far as possible ensure security to the patient, peace of mind to the operator, and brilliant results in a certain proportion of cases.

Gentlemen, I have invited a few of my patients to attend here this evening in order that you might have an opportunity of seeing the results obtainable by modern methods of extraction. Some of these present a notch more or less conspicuous in the iris, others have central and movable pupils; these last constitute the perfection of art, since art is to conceal art, and it would be difficult, if not impossible, for you to say whether they had been operated on or not. I introduced some patients, the subjects of double extraction treated in this way, to the notice of the members of the Clinical Society of London in 1878, and have since accumulated quite a number of similar cases. At the next lecture I hope to show you some novel methods of treating external and internal squints.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At the annual meeting on April 29th the following officers for the ensuing year were elected:—President: Dr. Cleaver. Vice-President: Mr. R. J. Pye-Smith. Treasurer: Mr. G. S. Taylor. Secretary: Mr. Simeon Snell. Additional Members of Committee: Dr. Keeling, Dr. Dyson, Dr. Porter, Mr. Thorpe, and Messrs. Garrard and E. Skinner. Pathological Committee: Dr. Gwynne, Mr. Atkin, Dr. S. White, and Mr. F. Harrison.

EXOPHTHALMIC GOITRE, AND OTHER CASES WITH ENLARGEMENT OF THE THYROID.

BY EDWARD SQUIRE, M.D., M.R.C.P.,
PHYSICIAN TO ST. GEORGE'S AND ST. JAMES'S DISPENSARY, ASSISTANT PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR DISEASES OF THE CHEST.

CASE 1.—Mary Ann V——, aged fifteen years and two months, came under my care in January, 1884, when the following notes were taken. She is short for her age (5 ft. ½ in.), and has never menstruated. The thyroid is enlarged, especially the right lobe, and this has been noticeable for three months. The neck is dark-brown in colour. The circumference of the neck over the thyroid is 12 in. The eyes are slightly but obviously prominent, and her mother says she has noticed this for the past three years; she attributes it to a fright. The heart's action is very violent; the apex beat is in the fifth space, but displaced to the left about an inch outside the nipple. There is a loud *bruit de diable* in the neck, and a hæmic murmur over the base of the heart. There are choreic movements in the left arm. A sense of constriction is felt in the throat on swallowing. In January of this year I had another opportunity of examining her. She has grown much taller, and menstruation began three months ago and is regular. There are still prominence of the eyes, enlargement of the thyroid, over-action of the heart, and a loud anæmic bruit in the neck; but she considers herself much better than when I first saw her.

CASE 2.—Emma W——, aged twenty-two, married two years (no children), was admitted in February, 1884, complaining of severe frontal headache and loss of appetite. The thyroid is considerably enlarged, and has been so for three months; its size varies, being larger at the menstrual period, and then causes difficulty in swallowing. The neck now has a circumference of 15¼ in. The eyes are sometimes painful, and project; this varies in extent with the variations in the size of the thyroid. There is excessive cardiac action, and faintness sometimes occurs. Menstruation is irregular, scanty, and painful. There is a brownish pigmentation of the face.

CASE 3.—Matilda R——, aged twenty, single. This patient came under observation in July, 1882, with sore-throat. She is stout, but not strong. The thyroid is much enlarged, the circumference of the neck being quite 14 in. She has always had a "full neck," but for the last four or five years it has at times been noticeably swollen, especially since she came to London three years ago. The last time it was as large as it is now was eleven months ago. It has been very big for the last three or four days, and is worse in the morning when she wakes, when it seems high up in her neck, "up to her chin," and causes a sensation of choking. She is now unable to fasten the collar of her dress. Menstruation is regular, though scanty, and is now present. The heart's action is very weak, but she complains of pulsation in the thyroid. There is a loud venous bruit in the neck, and a soft apex murmur. On Aug. 16th she had a hysterical fit in the evening, and states that before she came to London such fits were of frequent occurrence.

CASE 4.—Mrs. B——, aged twenty-two, married twelve months, and has one child three months old, which she has not been able to suckle. She was admitted in September, 1883, for cough, and had deficient resonance over the apex of the left lung. The thyroid is enlarged, and has been so for three years. It varies in size, but no connexion is noticed between the increase of the neck and the menstrual period, which has been regular. There is a loud anæmic bruit in the neck, but no hæmic murmur in the chest.

CASE 5.—Eliza R——, aged twenty, single. This patient, who is a stout well-grown girl, came under my care early this year complaining of lumbar pain. The thyroid is perceptibly enlarged, but causes no discomfort. The eyes are not prominent, and there is no over-action of the heart, though the patient complains of palpitation on exertion or after hurrying. There is a *bruit de diable* in the neck, and a soft hæmic apex murmur. Menstruation is regular, but scanty.

Remarks.—In the first two of the above cases we have examples of exophthalmic goitre, presenting singly no points of particular interest. They are described to be compared with those that follow. The first is a well-marked case, though the age of the patient is below that at which the disease is most common. The second, though a slight case, has all the essential symptoms—exophthalmos, enlargement of the thyroid, and increased cardiac action. Both of these show indications of the dark colouration of the skin which has been noticed in Graves' disease, and which is supposed to bear an analogy with the pigmentation seen in Addison's disease, depending on alterations in the sympathetic nerves and ganglia. The remaining cases are wanting in some one or more of the cardinal symptoms of Graves' disease, and cannot be so named if the concurrence of the three mentioned above is essential. According to the usual definition they are so; but the late Dr. Hilton Fagge, speaking of exophthalmic goitre,[1] warns us to be on the look-out for "slight cases in which one or two of the cardinal symptoms may be absent"; and Trousseau also insisted on this point, retaining the name "exophthalmic goitre" even when there is no exophthalmos.[2] Case 3 has enlargement of the thyroid, but with no prominence of the eyes; and the cardiac action is weak, instead of being over strong. She is anæmic and hysterical—conditions often associated with exophthalmic goitre; here the thyroid increases in size at the catamenial period as in Case 2. Case 4 has thyroid enlargement, which varies in degree, but without the periodicity noticed in these two cases. She has, like the last cases of the series, palpitation, but no exophthalmos. From one point of view, Cases 3, 4, and 5 would appear to be examples of simple anæmia, in which enlargement of the thyroid occurs as one of the symptoms. The question then arises, whether the enlargement of the thyroid may not be a result of laxity of the tissues—a loss of tonicity—due to malnutrition from impoverished blood-supply. Over-action of the heart is also a frequent symptom in anæmia, and we have only the exophthalmos to explain to bring Graves' disease down from its position as a separate disease to the level of several other conditions which were loosely spoken of as diseases in themselves (such as albuminuria and jaundice), and are now recognised as merely symptoms. Begbie mentioned chlorosis and anæmia as powerful factors in inducing Graves' disease, but later writers consider it more probable that anæmia is a result.[3] If so, it is sometimes a very early result, preceding some of the diagnostic symptoms of the disease. Graves himself thought that palpitation was the cause of the other two cardinal symptoms. Investigation with a view to discover a pathological cause for Graves' disease, has produced no very definite result. Some observers have found degenerative conditions of the cervical sympathetic, which have been found wanting by others in necropsies on patients who were the subjects of undoubted exophthalmic goitre. It would appear, therefore, that the prominence of the eyes is not dependent on this condition of the sympathetics alone. Exophthalmos has been ascribed to repletion of the orbital vessels, as the bronchocele to a similar condition of the vessels of the thyroid, which repletion is due to loss of vascular tone. The loss of tone in the vessels is explained as a result of paralysis of the vaso-motor nerves of the thyroid, head, and neck. May not this depend on the want of healthy blood-supply to those nerve-centres in common with the rest of the tissues. In anæmia we have many signs that the tissues suffer from the supply of impoverished blood. Muscular weakness is common; weakness of nerve-control is shown by the easily induced palpitation and cold sweats from slight shocks or emotions in these patients, and by hysterical manifestations; and vascular want of tone explains the swelling of feet and ankles. Caleb Parry describes[4] twelve cases of enlarged thyroid in women and one in a man, of which four of the female cases and that in the male he describes as associated with head symptoms. The remaining eight—of which the first, observed in 1786, has her eyes "protruded from their sockets"—he speaks of as "enlargement of the thyroid gland in connexion with enlargement and palpitation of the heart"; and places them under the heading "Diseases of the Heart." Three occur in youngish unmarried women, and are associated with palpitation; the remainder, including that with exophthalmos, are in older women, and appear to be associated with heart disease. In one of the former the

enlargement of the thyroid is attributed to a fright, and the tumour enlarges at the menstrual period. In all, throbbing of the carotids is noted. On these cases he makes the following comments: "Enlargements of the thyroid gland are not uncommon in females about the period when the body is fully formed and the menses are in a sort of wavering state. After both these points are completely established, they generally disappear if the health is otherwise good.....It is indeed true that these swellings occur most often and in the greatest degree in young females who have led sedentary lives, and who are of what are called relaxed and nervous habits." It has appeared to me that slight enlargement of the thyroid is not uncommon in anæmic and emotional women. If this occur without exophthalmos and palpitation, we look on it merely as a symptom of the general condition; but if all three are present in the same patient, we give a different name to the illness, and seek a different pathological cause. Advance in science usually tends towards simplification in classification. Have we not in this case arrived rather at greater complexity?

A CASE OF
COMPOUND FRACTURE OF THE PATELLA; PARTIAL NECROSIS OF ONE OF THE FRAGMENTS; RECOVERY WITH MOVABLE JOINT.

WITH NOTES OF NINETEEN OTHER CASES OF COMPOUND FRACTURE OF THE PATELLA.[1]

BY G. R. TURNER, F.R.C.S. ENG.,
DEMONSTRATOR OF ANATOMY AND JOINT LECTURER ON PRACTICAL SURGERY AT ST. GEORGE'S HOSPITAL; VISITING SURGEON, SEAMEN'S HOSPITAL, GREENWICH.

F. S——, aged thirty-two, married, sustained a compound fracture of the left patella by striking his knee against the kerbstone. The fracture was transverse, and over it was a nearly horizontal contused wound two inches and a half long, which freely communicated with the cavity of the joint, which was filled with blood-clot; separation of fragments, half an inch to an inch. The joint was syringed out with carbolic lotion (1 in 20), and full aseptic precautions used in the dressing and subsequent treatment of the case, there being no drainage other than that permitted by the wound. The case ran an aseptic course. There was no fever whatever. The wound would have healed readily but for a small sinus leading down to an exposed piece of the lower fragment. A sequestrum came away from this six weeks after the injury. Cicatrisation was soon afterwards complete. The patient has attended as an out-patient. He can now (March 16th) walk about and flex his knee very nearly to a right angle. The fragments are separated by about three-quarters of an inch when the limb is in the extended position; by about an inch and a quarter when the knee is flexed. The lower fragment is widened and irregular; at the outer part the skin is slightly adherent.

This case, I think, presents several points of interest: the transverse direction of the fracture; the little separation of the fragments; the aseptic course, although a portion of one of the fragments necrosed; the question of the immediate treatment of the injury, and when and to what extent passive motion should have subsequently been employed. Compound fractures of the patella are very often comminuted or -<-shaped, but both in Mr. Poland's cases in the fifty-third volume of the Medical and Chirurgical Transactions, and in some others I have collected, it is far from uncommon to find the direction of the fracture transverse. The fragments in compound cases appears often to be less widely separated than in simple ones; this may be due to the escape of fluid from the wound, or from the fact that muscular action has less to do with the causation.

The question of the immediate treatment in this case resolved itself into one either of suturing the fragments or simply leaving the wound alone, for I suppose that in these days of aseptic surgery few surgeons would be found to recommend either excision or amputation to a healthy man of thirty-two with a clean, although contused, wound over a fractured patella. I decided to adopt an expectant plan of treatment rather than suture, for the following reasons: the fragments were not at all widely separated; the injury was nearly twenty four hours old when I first saw the patient, and the case was doing well; there was sufficient drainage already provided by the wound; I could not tell to what extent the fragments were already injured, and, consequently, whether they would bear the strain of wiring. From the subsequent necrosis it would appear that it was well they were not subjected to further mechanical injury. Passive motion was necessarily delayed until the separation of the sequestrum and the final union of the wound. When cicatrisation first occurred there was considerable prominence of a pointed fragment, and it seemed as if very slight violence would cause this to perforate the skin. I have on several occasions flexed the limb as far as I dared, but the fragments being as yet united by fibrous tissue, I have been afraid of stretching or rupturing the uniting band.

It may be interesting to compare the results of Mr. Poland's cases, published in 1870, with some recent cases which have occurred since the more general adoption of antiseptic surgery. In Mr. Poland's eighty-five cases the treatment adopted was "strapping where permissible, ice, leeches, irrigation; and in the suppurating stage fomentations and free incisions, opium, tonics, and support." Mr. Poland divides his cases into those with incised wounds, of which six recovered and two died; those with lacerated and contused wounds, of which thirty recovered and nine died; those associated with gunshot wounds, of which eighteen recovered and threedied; those associated with lesions of other bones, of which ten recovered and six died: total, eighty-four recoveries and twenty deaths. The joint suppurated in sixty-three cases, and of those that recovered thirty-one had more or less complete ankylosis. The above statistics, as Mr. Poland observes, probably give too favourable a view of the result of such treatment, as successful cases more often find their way into newspapers than the unsuccessful. This remark will apply with equal force to the cases I am about to relate.

Mr. Rouse has had two cases at St. George's Hospital. 1. Henry R——, aged forty-seven, fell on to his right knee from a height of from twelve to fourteen feet, striking it against the pavement. There was a small lacerated wound over the patella, which was obliquely fractured across the centre. There was half an inch separation of the fragments, the lower of which consisted of two pieces, the external wound corresponding to a depression between them. Antiseptic precautions were used, and a ham splint applied. The temperature rose on the third day to 101° in the evening, otherwise it was normal throughout. The patient recovered with a perfectly movable joint. 2. Edward B——, aged thirty-three, fell from a cart on to his left knee, sustaining a compound comminuted fracture of the patella, over which was a circular contused wound, "which evidently communicates with the joint, although no synovia escapes." The wound was syringed out with carbolic lotion and dressed antiseptically with carbolic gauze. The temperature rose to 100° in the evening, otherwise it was normal throughout the case. The patient recovered, with a movable joint, without any bad symptom whatever.

Mr. Pick read before the Clinical Society on Oct. 18th, 1875,[2] a case of extensive wound of the knee-joint treated by Lister's antiseptic method, in which the patella was divided by a circular saw and the condyle of the femur wounded. The joint was washed out with carbolic lotion (1 in 40). Suppuration followed, and the patient, a young man aged eighteen, recovered with firm bony ankylosis of the joint.

Mr. Finlay[3] records a case of bullet-wound of the knee-joint in which the patella was "grooved" by the projectile, which finally lodged in the femur. The wound was washed out with carbolised water, the bullet extracted, and carbolic oil employed as a dressing. A little fever followed, but the patient, a man aged thirty-one, recovered with a perfect joint.

Mr. Wheelhouse[4]—Margaret M——, aged twenty-four, fell some twelve feet on to her right knee. Clean transverse wound; fragments half an inch apart; no comminution except one small splinter from upper one. Wound enlarged; joint cleared of blood and washed out with 1 in 20 carbolic lotion. Fragments drilled and wired. No drainage of any kind. Full aseptic precautions. Wound ran an aseptic

Digitized by Google

course. Patient able to flex knee beyond a right angle. Injured patella as sound as the other.

Mr. Jessop:[5]—Robert L——, aged seventeen, fell into a quarry, striking bent right knee on a steel rail. Brought to the hospital eleven hours after this; the wound full of sand and mud. Compound comminuted transverse fracture of patella; fragments separated half an inch; severely contused wound. Wound purified; joint irrigated for nearly an hour. Fragments wired; posterior drainage. Free suppuration followed. Wire removed on thirty-sixth day. Full aseptic precautions throughout. Some adhesions broken down by passive motion. Patient eventually recovered with absolutely perfect movement of joint.

Mr. Ormsby:[6]—James B——, aged twenty-four, was struck by a puncheon on his left knee, receiving a compound fracture of the patella, with two inches' seperation of the fragments. Wound sealed by pad of lint soaked in blood. Evaporating lotion applied; long posterior splint; no bad symptom. Wound healed without suppuration. When discharged he was able to walk without the help of crutches.

Mr. Manser:[7] — B. W——, aged thirty-six. Gunshot wound. Comminuted fracture of femur and patella; lodgment of pointed piece of gun-barrel in external condyle of femur. This was removed. Attempted antiseptic treatment. Erysipelas of thigh, scrotum, and abdomen. Antiseptics discontinued. Symptoms extremely grave, but patient ultimately recovered with firm fibrous ankylosis of knee.

Dr. John M'Diarmid:[8] — J. B——, aged sixty, a female drunkard, leapt out of window two storeys high and struck her left knee against the edge of a cart-wheel tire. Seen twelve hours afterwards. Transverse wound two inches and a half long opening into joint; patella fractured; lower fourth splintered; ligamentum patellæ divided. Loose fragments removed; wound washed with water, and lint steeped in 1 in 20 carbolic oil laid over the knee; long padded Gooch's splint applied. Treated by cold lotions, the wound itself being protected by lint steeped in carbolic oil. Favourable course; recovered; able to bend knee almost to a right angle and to walk up and down stairs.

Volkmann[9] mentions two cases of compound comminuted fracture of the patella, both of which recovered with movable joints. They were treated antiseptically.

Mr. Langley Browne reports a case:[10]—Isaac C——, aged thirty-five, received a wound from an axe on the left knee. Wound oblique, two inches and a half long. Patella divided into two pieces; knee-joint enormously distended with clot, which was turned out. Lister's dressings and treatment were employed. The joint was washed out with carbolic lotion, and was dressed for the first time on the ninth day; there was no pus; it was quite healthy. On the sixteenth day the wound had healed, and a pasteboard and starch splint was applied. On the thirtieth day he was discharged cured (no note as to separation of fragments, method of union, or mobility of joint).

Dr. Stimson:[11]— Edward C——, aged twenty-two, fell from a pillar of an elevated railway, receiving a transverse fracture of the patella below the centre; there was no comminution or bruising. There was a clean-cut transverse wound an inch and a quarter long; the wound was dressed with carbolised gauze. Next day he was first seen by Dr. Stimson. The wound was then enlarged, the fragments sutured with silver wire, and gauze dressings applied. Some suppuration on the outer side of the lower portion of the thigh followed, otherwise the wound did well. When discharged, the patellar fragments had united by a fibrous band a quarter of an inch long. Ten days afterwards he could flex the joint 10° without pain. A month afterwards a small fragment of the patella just under the skin above the drainage opening on the outer side was removed. This had evidently been keeping up suppuration. When last seen the mobility of the joint was increasing.

Mr. W. Thomson:[12]— T. G—— had been operated on by the late Mr. Amplett for ununited fracture of the patella. Osseous union was obtained, but the joint remained stiff. He fell and laid open the knee-joint, refracturing the patella at the seat of the old injury. Excision of the joint was performed, and he recovered with some three-quarters of an inch shortening.

Mr. James has had two cases:—1. A. J——, aged twenty-seven, struck his knee against the sharp edge of a water-plug, receiving a lacerated wound two inches long, communicating with a transverse fracture of the patella, the fragments being widely separated. Cavity of joint freely laid open, and a quantity of blood effused into it. Blood squeezed out; long back splint; foot suspended; interrupted side outer splint; perforated zinc splint on inner side. Joint syringed out with carbolic oil (1 in 20). Lister's dressings and method. Dressed under spray every second day. On the eighth day a rise of temperature to 102°; otherwise no fever. The wound healed on the twenty-eighth day. "Three-quarters of an inch interval between the fragments; able to bend the knee slightly, and states that the amount of flexion is increasing; able to walk ten miles without a stick."[13] 2. C. H——, aged thirty-five, half caste. Twenty-four hours before admission she jumped out of a vehicle while the horse was bolting and fell on to a heap of loose metal, against which her left knee struck with great violence. Compound fracture of the patella ensued, which was greatly comminuted; large lacerated wound across the front of the knee-joint. The wound was thoroughly washed with carbolic lotion and dressed antiseptically. Back splint suspension from cradle. Fever and pain for two days. Incision on the outer side of the joint. Fragments of the patella, which were widely separated and covered with decomposing clot, were removed. The extensor tendon and ligamentum patellæ were approximated by two sutures of gold wire and one of kangaroo tendon. Antiseptic dressings. Some sloughing and burrowing of pus on the outer side of the joint followed. Mr. James remarks: "Severe case; joint filled with road dirt; many hours since accident; from present condition I believe she will have fair joint motion in time."[14]

Mr. Davies-Colley has treated two cases of compound fracture of the patella antiseptically. In one case a silver wire was passed right through both fragments. He saw the man a few weeks ago; he could then walk well. His leg was nearly straight, and the range of movement was only 3°. The patella could be moved a little from side to side. Mr. Davies-Colley writes: "I thought that by passive motion he might improve it considerably, but I dared not bend it forcibly, as the bony union did not extend over the whole breadth of the patella. At the side of the bone was a deep notch left by the removal of a fragment. Since this case I have treated another patient under more favourable circumstances—i.e., from an hour or two after the receipt of the injury. I had not to wire the fragments, and bony union resulted with perfect movement, the condition of the wound having remained aseptic throughout."

I am indebted to Mr. Battle for the following case, which was under the care of Mr. Sydney Jones at St. Thomas's Hospital:—"A. B——, a male, aged nineteen, strongly built and heavy, fell down a lift, striking his knee on a bar below. The wound extended across the tendo patellæ, and there was comminuted fracture of the patella. The wound formed a flap over the front of and into the joint, and carried upward the greater part of the bone. The bone was wired soon after admission, with lateral drainage. The patient recovered, with partial movement. There was good union."

Summary of above cases.

Total cases, 20. All recovered: 12 with good movement, 5 with slight movement. In 3 ankylosis occurred (one after excision of joint).

Antiseptic treatment (without suture): 9 cases, of which 7 recovered with good movement, 1 with partial movement, and 1 with bony ankylosis.

Antiseptic suture: 5 cases, of which 2 recovered with good movement, 3 with partial movement.

Carbolic oil to wound: 2 cases, both of which recovered, with good movement.

Lint soaked in blood applied to wound: 1 case; good movement.

Removal of patellar fragments; suture of quadriceps to ligamentum patellæ: 1 case; slight movement.

Excision of knee: 1 case.

Antiseptic treatment for a time: 1 case; fibrous ankylosis of joint (complicated with erysipelas and lodgment of piece of gun-barrel in condyle of femur).

ON THE NATURE OF WHOOPING-COUGH;

WITH A DESCRIPTION OF A NEW MODE OF TREATMENT INTRODUCED BY PROFESSOR MONCORVO, OF RIO DE JANEIRO, AND ITS PRACTICAL RESULTS.[1]

BY WILLIAM H. BARLOW, M.D.,

CONSULTING PHYSICIAN TO THE DISPENSARY, GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, MANCHESTER AND PENDLEBURY.

THE disease which I am about to consider, pertussis or tussis convulsiva, and in English chin-cough or whooping-cough, has been known probably since A.D. 1414, and certainly since 1510. It is one of the most common and universal of diseases, and yet its true nature and etiology is as much a subject of controversy now as in the days of Sydenham. There has been no lack of subjects for observation, nor, from its very nature, is there much difficulty of diagnosis, and there is little reason to doubt that in time past the epidemics of whooping-cough recurred with the same regularity as they do now, and, as we know by the charts compiled from the Swedish statistics and published by Professor Arthur Ransome,[2] that they have done so since 1775. Cullen,[3] Brouzet,[4] Pinel,[5] and several others have placed the origin in irritation of the gastric and intestinal surfaces. Padalme[6] associates with these the lungs and the diaphragm. Watt,[7] Allcock,[8] and Laennec consider it as a spasmodic variety of bronchitis, and Broussais[9] adds to this an exaggerated irritability of the mucous lining of the inflamed bronchi. Trousseau[10] and Richard de Nancy[11] believed it to consist of a bronchitis grafted upon a neurosis. Albers, of Bonn,[12] found in three cases out of forty-seven in which a careful post-mortem examination was made the vagus nerve on the right side inflamed, and in one that of the left side. Dr. Charles West[13] records a similar observation in one case out of twenty-four, and remarks that "an appearance so frequently absent cannot be of much moment"; in this case both nerves were affected. Webster[14] considered the true seat of the disease to be the encephalon, and Desruelles[15] was of a similar opinion, and even designated it by the name of "broncho-encéphalite." The peculiarities of this disease, its definite period of incubation (fourteen days), and the frequency with which the epidemic cycles coincide with those of measles, or closely follow or precede them, have not escaped the notice of observers, and have of late years been graphically placed before us in the charts of epidemic disease prepared by Dr. A. Ransome, and published by the Sanitary Association, borne out as they have been by the long series of Swedish statistics, charts of which have been published by the same accomplished physician in the work to which I have before alluded (see note 2). These observations have led many (notable among whom we find Rokitansky and MM. Barthez and Rilliet[16]) to believe the disease to be a specific fever analogous to the eruptive fevers, and some have even gone so far as to assert the identity of measles and whooping-cough. This latter opinion has been supported by Professor Germain Sée.[17] Gueneau de Mussy[18] also admits the very closest relations between these diseases. In this regard also may be here quoted certain replies made by forty-seven medical practitioners, to whom the following questions had been addressed by Dr. Octavius Sturges, who publishes the same in his "Lectures on some of the Distinctive Characters of Disease in Early Life."[19] "1. Have you met with pertussus arising out of catarrh, measles, &c., but, so far as could be ascertained, apart from direct infection? If so, how many within (say) the last three years? 2. In what proportion of such cases has pertussis been prevalent at the same time in the immediate neighbourhood?" Of the forty-seven replies eight say "No" to both questions, ten say "No" to the first and vary as to the second, six are doubtful, but twenty-three say "Yes" to the first question and answer variously as to the second. The main result shows that more than half the number of men engaged in active practice who were appealed to believed themselves to have seen the cough develop from measles or catarrh. He gives a case in detail, which is related by Dr. Donkin, of Westminster and the Shadwell Children's Hospitals, which, as it comes with the name of a competent observer, and is in itself a good example of the cases, I will quote. "Two boys," says Dr. Donkin, "aged three and five, had scarlet fever, and were confined to two communicating top rooms of the house, no one being suffered to see them except their father, a medical man, and a nurse who was constantly with them. For about a week, during the father's absence, another doctor visited them. Both children had marked bronchitis during the fever, and one had broncho-pneumonia. About five weeks after the onset of the scarlatina both began to whoop, and both continued to suffer from typical whooping-cough for many weeks after recovery from all signs and sequelæ of scarlet fever. During the whole time of their isolation a carbolised sheet was hung outside the door, and carbolised vapour or creasote was constantly diffused through the rooms." Dr. Sturges seems to think that this history is not to be accounted for except by a theory of spontaneous evolution, or on the hypothesis that there is no limit of time for incubation or "of space or agent, through which the contagion may travel." I venture, however, to suggest a more homely explanation of this and other similar cases which have not unfrequently puzzled the practitioner. All who have had practical experience of the management of infectious or contagious disease in children at their own homes will agree with me as to the difficulty, even under the most favourable circumstances, of maintaining perfect isolation for any lengthened period, and especially does this become difficult as convalescence proceeds. There was a nurse there; there was a strange medical man, and both he and the father might have visited cases of pertussis: who can say that no neighbour's child could have been admitted to the room? True, there were disinfectants and the carbolised sheet at the door, but this latter popular antiseptic placebo is, in my humble opinion, of more value in the treatment of the parents than protective to the patients, and my experience of vapours of creasote and carbolic acid shows that if they are strong enough to be of any value as antiseptics, they are too strong for the patient; but of this I shall have more to say hereafter. Moreover, if whooping-cough were identical with or developed from either of the exanthematous fevers, we should find their cycles coincide, either absolutely or in sequence, which is clearly not the case.

A glance at Dr. Ransome's charts will show that, though the epidemic cycles of this disease and of measles form arcs of circles of a very similar radius, yet there is no absolute coincidence, the highest points of these curves sometimes preceding, sometimes following, in some cases corresponding to the lowest points of the other, and very rarely coinciding. In the case of scarlet fever there does not seem to be any relation whatever; but in the case of bronchitis and catarrh there is a rough agreement in the curves, not always but very generally coincident. In the case of Sweden the curves are of much greater radius, the highest points being attained in an unbroken series of statistics, extending from 1775 to 1830—in the case of measles at an average interval of a fraction over seven years, and in the case of whooping-cough a fraction under five years.[20] Out of fifty cases of whooping-cough which I have observed for the purpose of this paper, I have found that in no case has the cough either coincided

[20] Ransome, loc. cit. (note 2). The exact numbers being for measles an average interval of 7¼ years, and for pertussis 4⅞ years. The numbers for scarlet fever show no kind of proportion, the exact numbers of years intervening between the epidemics being 4, 4, 4, 5, 13, 2, 4 years: but the second, fourth, sixth, and seventh were very much lower figures than the others, and the highest figure recorded is the last. The numbers, it is to be noted, represent the deaths, and that they were registered by what Dr. Berg of Stockholm calls in his letter to Dr. Ransome "ecclesiastical registrars," doubtless meaning the pastors of the various parishes or their equivalents, who may sometimes have made erroneous diagnoses; but this source of error is scarcely likely to have affected in any marked degree the cases of such easily recognised and popularly known diseases as whooping-cough, or even measles, though it may not improbably have some effect upon those of scarlet fever.

Digitized by Google

with the outbreak or preceded the eruption; but my wider general experience furnishes me with many cases of convulsive, crowing inspiration simulating croup, which have been relieved by an outbreak of measles; and in several instances the latter disease was followed by whooping-cough. In twelve cases out of fifty the attack of measles was followed by whooping-cough at a period varying from three months to three weeks. In one case there had been a cough ever since an attack of measles twelve months previously, which developed into whooping-cough, while the child was under observation. A recent writer to whom I have already referred, Dr. Octavius Sturges,[21] has promulgated the opinion that the whooping is simply a nervous adjunct to an epidemic catarrh,[22] and he quotes Bouchut[23] thus: "Whooping-cough is transmitted like a large number of nervous affections—like hiccough, vomiting, hysterical attacks, &c."; and he complains that Dr. West has dismissed the notion with something very like contempt. There is no doubt that the disease does present some points of resemblance to the pure neuroses, but have we not overwhelming proof of a definite and distinct period of incubation?—and how upon such a supposition is this to be accounted for? His strongest argument seems to be the immunity of children's hospitals, and in this he is quite corroborated by the experience of the Hospital for Sick Children at Pendlebury, and probably the practice there may give the explanation of the fact. It is the custom to refuse to admit cases where the cough is already developed, and when a case arises it is sent home at once, except in one or two exceptional cases, which have been treated in a special ward. Now the contagion of most zymotic diseases is much less virulent in the earlier stages, and in Pendlebury Hospital, at any rate, the special wards are as carefully isolated from the general wards as are these from each other, and it is probable that the area of infection is less in this disease than in most others. At all events, we do not find that the power of infection is in any degree lost when the patients are removed to their own homes, and although we may allow that, as with other undoubtedly infectious diseases, there may be occasional sporadic cases of whooping-cough, yet we are inclined to attribute these to causes which have escaped discovery from defective knowledge and want of opportunity for complete investigation rather than allow them to form a reason for denying the specific nature of the *materies morbi*.

Continuing our history, not in chronological, but rather in an anatomical order, we find Dr. Ebenezer Watson, of Glasgow,[24] used topical applications to the larynx, and five years later we find him complaining of the little attention which had been paid to this mode of treatment. Gendrin[25] considered that the seat of irritation was in the isthmus of the larynx; and Beau[26] published three necropsies in which he found an exaggerated inflammatory redness of the mucous membrane which lines the supra-glottic portion of the larynx. Dr. West also mentions[27] finding "a state of extreme irritability about the fauces"; and a little later the observations of the former two authors were corroborated by two new necropsies by the late Prof. Parrot. Still more recently Vannebrough[28] by four necropsies, and E. Lelu[29] by two others made in 1874 at the Hôpital des Enfants at Paris, have verified the existence of similar conditions.

(To be continued.)

[22] Sturges, loc. cit. I quote his conclusions here, so as to avoid any misrepresentation. "1. Convulsive (or whooping) cough is a purely nervous phenomenon, the expression of a special liability of childhood in respect of spasm, of which other illustrations are to be found in laryngismus and spasm of the glottis. 2. Pulmonary catarrh in young children may at any time give rise to convulsive cough, and does, as a fact, frequently give rise to it apart from any special infection." Of the second proposition the evidence he quotes does not seem to me to be conclusive.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the next quarterly meeting of this Association, to be held at Bethlem Hospital, on May 19th, at 4 P.M., Dr. Savage will read a paper, entitled "A case of Insanity cured by removal of the Beard in a Woman;" and Dr. Percy Smith one on "Notes on a case of Ovariotomy in an Insane Patient."

THREE CASES OF ŒDEMATOUS LARYNGITIS THREATENING SUFFOCATION,

SUCCESSFULLY TREATED BY ENDO-LARYNGEAL SCARIFICATION.

BY GEORGE MACKERN, M.D. LOND.,
PHYSICIAN TO THE BRITISH HOSPITAL, BUENOS AYRES.

CASES of acute œdematous laryngitis present symptoms of so urgent a nature that usually but little opportunity is afforded of making an accurate laryngoscopic examination on which a scientific treatment may be based. In each of the following cases a satisfactory examination of the larynx was obtainable, and I venture to publish them that others may be encouraged to adopt a similar direct treatment in the dangerous condition of œdema within the larynx. These cases, though differing widely in the character of the primary disease, agree in the severity of the secondary laryngeal symptoms, and in the promptitude with which these symptoms yielded to similar surgical measures. In all complete aphonia was present, and the patients were in such evident danger of a fatal apnœa that tracheotomy instruments were kept ready at hand in case immediate relief were not given by the scarification.

CASE 1. *Solitary syphilitic gumma situated on the cricoid cartilage; gradually supervening œdema of the whole larynx.*—N. Y——, a native of Buenos Ayres, aged forty, of no occupation, was first seen by me in consultation with Dr. Alston on Dec. 13th (the middle of summer here). The personal history showed that, years before, the patient had gone through the usual stages of syphilis, and that he had recently suffered much from pains in his head and in the osseous system generally. Up to this date, however, no nodes or external gummatous formations had ever been observed. Two years previously he had suffered from what appears to have been paroxysmal hæmatinuria, and recovered under treatment at Naples. It must also be noted that he had never been troubled with his throat till the present attack. The patient stated that three weeks previously he first began to complain of pain and difficulty in swallowing, and he also noticed he was getting hoarse. As he was about to embark on a long journey up the river, he consulted his medical adviser, who, without examining the larynx, told him he might go in safety, and prescribed a simple gargle. He returned on the 12th, feeling very ill and breathing with difficulty, but he had not had any actual spasmodic attacks of dyspnœa during the voyage.

When seen on Dec. 13th, he was a tall, thin man, of dark complexion. He had an anxious expression, and the voice was reduced to a mere whisper. Respiration was slow and laboured; the inspirations noisy, but not accompanied by "downward excursions" of the larynx. There was a short, dry cough, and occasionally a scanty mucoid expectoration. He had passed several bad nights, being unable to lie down on account of dyspnœa. He had had no actual spasms—i.e., severe and sudden attacks of dyspnœa, thus contrasting with the other two cases, where this symptom was very pronounced. (I would draw here particular attention to this, as serving, perhaps, to distinguish a gradual œdema from the more acute variety; in the former case the respiratory centre had time to accommodate itself to the increased amount of carbonic acid in the blood, while in the latter the poisoning was more acute.) Externally there was nothing noticeable about the larynx except some tenderness on pressure. On laryngoscopic examination the mouth and pharynx were quite normal. The examination was made by the aid of a Mackenzie lamp, and a good view of the larynx was obtained with ease; in fact, there appeared to be some anæsthesia of the soft palate and parts around (toxic effects of CO_2 circulating in the blood?), which allowed of free use of the small mirror. The epiglottis showed no marked change, the tip and edges being merely somewhat more congested than usual. The larynx proper, however, was intensely congested, the right half being more especially so. The mucous membrane over the arytenoid cartilages and ventricular bands (false vocal cords) was much swollen, the lumen of the glottic opening being reduced to a mere chink, through which the air passed in frothy bubbles. The swelling was not equal on both sides owing to the greater tumefaction of

Digitized by Google

the right side, and the chink of the glottis appeared oblique and inclined towards the left. The vocal cords were not visible, being completely covered by the greatly swollen ventricular bands. On the right half of the cricoid cartilage, just behind the corresponding arytenoid cartilage, a whitish swelling was seen, circular in shape, about half an inch in diameter, with its circumference sharply defined, and its surface smooth and glistening, contrasting vividly with the surrounding congested tissues. When touched with the laryngeal probe, the tumour felt elastic and semi-fluid. No ulcerations of any sort were to be seen in the larynx. Reserving the question of the nature of the tumour for discussion later on, it was evident that its presence, in the absence of all other causes, was the cause of the œdema, because the parts immediately surrounding it were intensely inflamed, and the œdema, on the whole, was greater on that side of the larynx.

Owing to the dangerous amount of dyspnœa present, I was afraid to attempt the removal of the tumour at once, but determined to reduce the œdema directly. Accordingly I passed a guarded laryngeal lancet with the aid of the mirror, and made several punctures into the œdematous mass. Some drops of dark blood immediately escaped, and I was quite astonished at the little spasm and irritation excited by the operation. Strong blistering fluid was then painted over the thyroid cartilage in front of the neck, and hot inhalations of compound tincture of benzoin were recommended for five minutes every hour, also ten grains of bromide of potassium with two grains of the iodide to be given every two hours during the night. The effect of the inhalations was to cause a considerable flow of frothy and blood-stained mucus and saliva. Next morning I found that the temperature had become lowered from 101·8° to 100°, and that the patient had slept for about an hour. He was still suffering much from dyspnœa, and finding that the œdema had decreased but slightly, I again scarified, and very freely this time; a more abundant flow of blood was the result, and a strong spasm. I had to change the bromide of potassium for the soda salt and to leave out the iodide, on account of stomach irritation. Next day he was much better, had slept at intervals during the night, and his face had a less anxious expression, but there was still much stridor on inspiration. On the next morning, as considerable improvement had taken place and the chink of the glottis was more open, I determined to cut into the white tumour, believing it to be an abscess. With a long curved bistoury and the aid of the mirror I cut right across it, but with a negative result—scarcely a drop of blood. Then with sharp laryngeal forceps I seized the tumour and removed it easily from its bed; no hæmorrhage resulted, and but slight spasm was provoked. The site of the tumour was pale pink, granular-looking, and was probably eroded cartilage, as it felt rough to the laryngeal probe. On examination, the tumour was of the size of a hazel-nut, of firm consistence, semi-transparent, and its capsule was tough, fibrous, and quite adherent; it had been completely divided by the bistoury. The microscope showed the little tumour to be a typical gumma. The case then went on well to recovery. Some ulcerations appeared along the free border of the right ventricular band, but there was no exfoliation of cartilage or any more œdema. The patient was put on iodide of sodium, and in three weeks' time his voice had almost recovered its natural timbre and he had gone to the seaside to recruit.

Remarks.—The diagnosis of the white swelling lay between abscess and a syphilitic gumma. If abscess, it would probably be of perichondritic origin, and against this were (1) the short history of laryngeal trouble, (2) the little pain, and (3) the slight tenderness on pressure. As a rule, in perichondritis of the larynx there is much pain, and considerable tenderness on pressure externally. Against the gumma was the absence of all other signs of syphilis in the larynx; there were not even ulcerations on the epiglottis. I decided on abscess on account of the physical signs, the white appearance, and the elastic feel to the laryngeal probe. Another point of interest in the case was the tolerance for examination and instrumentation.

CASE 2. *Acute œdematous laryngitis by contiguity from pharyngitis; great swelling of left arytenoid cartilage and ventricular band; endo-laryngeal scarification, followed by recovery, with ankylosis of the crico-arytænoid articulation and permanent immobility of the left vocal cord.*—R. C——, a short, thin, dark-complexioned man, a native of Paraguay, aged forty-six. I was called to see this case in consultation on the tenth day of his illness, which began with acute pharyngitis. The laryngeal symptoms had come on only during the last two days, and were urgent from the beginning. I found the patient propped up in bed, with an anxious expression of face, severe inspiratory dyspnœa, quick and small pulse, moist skin, completely aphonic, unable to swallow on account of dysphagia, and with a temperature of 101·6°.

On examination the pharynx was much inflamed, and the left side was so swollen and the mucous membrane of such a peculiarly livid hue, that I inclined to the opinion that we were dealing with a case of pharyngeal erysipelas. Externally, the left side of the neck was swollen and brawny to the touch, and there was much tenderness on pressure over the left side of the thyroid and cricoid cartilages. The laryngoscopic examination was difficult, and was made by the aid of direct sunlight in the courtyard, to which both bed and patient were conveyed. The epiglottis was found to be excessively red and injected, but not swollen or œdematous. The whole left side of the larynx proper, however, was immensely swollen, and the mucous membrane of a dark livid colour. The right half of the larynx was somewhat congested, and the glottic chink was pushed over and lay obliquely towards the right, but a small portion of the right vocal cord could be seen.

With the aid of the mirror and Mackenzie's lancet, I cut deeply into the œdematous mass in the larynx. About a teaspoonful of dark blood escaped, but such a terrible spasm of dyspnœa resulted that for a moment I thought the patient would succumb. The spasms before this had been frequent but not very alarming. Recourse was had immediately to steam inhalations of compound tincture of benzoin, and blisters and poultices applied over the thyroid cartilage externally. With great difficulty a mixture containing bromide of potassium was swallowed, as the act of deglutition invariably brought on a paroxysm of dyspnœa. In a day or two the urgent symptoms had passed off, and the case subsequently did well. When I last saw him (more than two years after the operation) he had no respiratory trouble, but his voice was hoarse, and he had tumefaction of the left crico-arytænoid articulation, with fixation of the corresponding vocal cord in the cadaveric position.

Remarks.—This case may be put down as one of very acute laryngitis propagated from an erysipelatous pharyngitis, and the paroxysms were frequent and dangerous owing to the acuteness of the laryngeal complication. The permanent injury to the crico-arytænoid articulation is not to be wondered at when we consider the delicate construction of this joint and the septic nature of the inflammation propagated from the pharynx.

CASE 3. *Acute œdematous laryngitis of three days' duration; cause uncertain; extensive œdema of the epiglottis and upper rima glottidis; scarification, with immediate good result.*—C. M——, a Scotch gentleman, aged thirty-six. No history of previous illness, nor had he ever suffered from his throat before. I was called to see this case in consultation with Dr. Ayer, at half-past nine o'clock one morning. I found the patient sitting up in bed with a most anxious expression of face, great inspiratory dyspnœa, short dry cough, dysphagia, complete aphonia, quick pulse, skin moist, pale face, and a temperature of 101°. The illness, which was only of two days' duration, had begun with hoarseness and dysphagia; fever, with headache and loss of appetite, had also been noted. He had passed a sleepless night, was very restless, with threatening paroxysms of dyspnœa, and had got rapidly worse since five o'clock in the morning. Examination, by means of direct sunlight, revealed a normal pharynx. But the epiglottis was immensely swollen and congested, especially its laryngeal surface, which resembled a roll of sausage of a dark purple colour. A glimpse only of the posterior part of the upper rima glottidis could be obtained, which showed a certain amount of swelling and congestion there also; the rest of the larynx was completely hidden by the swollen epiglottis.

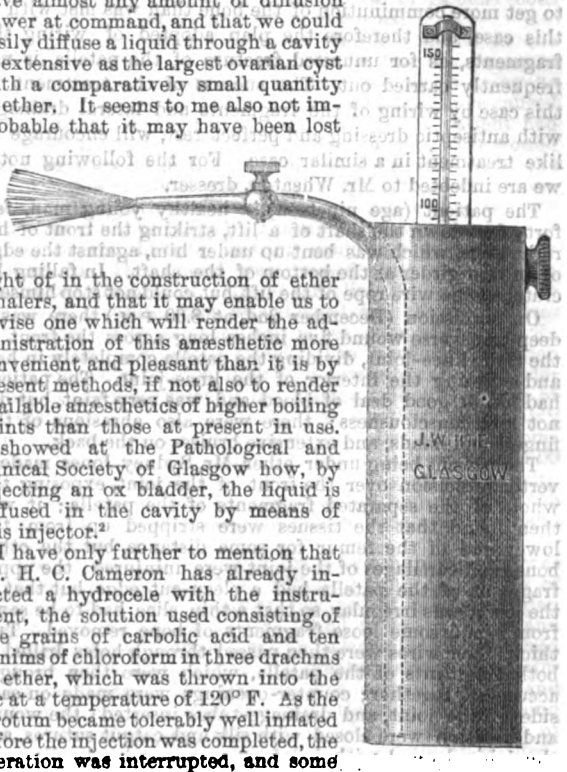
As the symptoms were very urgent, I at once punctured the epiglottis with a Mackenzie lancet, but the tough tissue of the epiglottis appeared to resist, and only a few drops of blood escaped. I went home to get a more powerful instrument, and on my return at 11.30 I found that several severe paroxysms had taken place, necessitating the use of nitrite of amyl. The second operation was more successful, about a drachm of dark blood escaping. Blistering and steaming inhalations were then used as in the other two cases, but no bromide was given owing to the dysphagia produced by the swollen epiglottis. The dyspnœa gradually became less, and

Digitized by Google

no more paroxysms took place. The urine was found to be albuminous, and the temperature remained above 100° for nearly a week, although the throat gave no more trouble, and the voice was completely restored in a fortnight.

Remarks.—The etiology of this case is by no means clear in the face of what authors state—namely, that the occurrence of extensive œdema of the larynx in simple uncomplicated acute laryngitis is extremely rare. In this case there was a history of rigor at the commencement of the illness, but there were no other symptoms of an influenza type present. The presence of albumen in the urine and the continued high pressure made me suspect an acute diphtheria at first, but a most careful laryngoscopic examination failed to show the presence of any membranous deposit. From the acuteness of the attack, the great swelling in the larynx, and the lingering convalescence (three weeks), with feverishness, I, however, concluded that some zymotic or other septic cause must have been at work.

Buenos Ayres.



ON A NEW SYRINGE OR INJECTOR FOR SURGICAL PURPOSES.[1]

By ROBERT KIRK, M.D. EDIN.,
OUT-DOOR PHYSICIAN-ACCOUCHEUR TO THE GLASGOW WESTERN INFIRMARY.

THE object of this instrument is to produce perfect diffusion of liquids injected into closed cavities. With our present appliances we have no means of doing so, and in the case of hydrocele we resort to shaking and manipulation of the scrotum for this purpose—a proceeding, however, which is impossible where internal cavities are concerned. Now, it is a matter of daily observation that liquids are driven and widely diffused by means of vapour, an illustration of which is the familiar phenomenon of a pot "boiling over." Nearly two years ago it occurred to me that in ether, which boils below the temperature of the blood—namely, at 95° F.,—we had an agent exactly suited to the purpose in view. Accordingly I proceeded to treat such cases of hydrocele as came in my way by injecting the sac with ethereal solutions of carbolic acid, heating the liquid to near its boiling point before injection. The acid has been somewhat extensively used for hydrocele in America, though in much larger quantity than I thought necessary, and I have never exceeded five grains in each case. Of four cases thus treated the first three were very successful; the pain was much less than with the iodine treatment—indeed, was practically *nil*, while the recovery was rapid, the patients being allowed to resume their ordinary employments in a week. It is now seven months since the last of these cases was treated, and there has been no return of the affection in any of them. The ordinary piston-syringe, however, proved in all the cases a very unsatisfactory instrument for the purpose, as it was very difficult to draw heated ether into it; and the failure of my fourth case, which was complete, the effusion returning in a few months, was entirely due, as I believe, to the extremely faulty action of the piston on that occasion. This led me to devise the injector I am about to describe.

Experiments in injecting the urinary bladders of oxen with ethereal solutions, while they were held in a vertical position, having shown that a temperature of from 110° to 120° F. was necessary to produce perfect diffusion of the injected liquid, with inflation of the viscus, it occurred to me that the vapour-pressure of ether would of itself be sufficient at this temperature to drive the liquid, and this principle will at once explain the construction of the instrument. It consists, as represented in the accompanying woodcut, of a cylinder into which passes a tightly-fitted thermometer, and which is further provided with a filling aperture, closed by a screw stopper, and lastly, with an exit tube which dips down to the bottom of the cylinder. This tube is furnished with a stop-cock and terminates in a nozzle with a very fine aperture, and of such a size as to fit into an ordinary hydrocele cannula. The vapour-pressure within this cylinder acts on the liquid and drives it through the tube, and the vapour alone cannot escape till all the liquid has been driven out. Such is the vapour-pressure of ether that the heat of the hand expels the liquid with considerable force; at 80° F. it is driven out in a stream six or seven feet long, and at 85° the internal pressure is sufficient to expel all the liquid which the vessel can hold when full. Ether can also be made to drive other liquids at temperatures quite comfortable to the body. Three parts of rectified spirit and one of ether produce sufficient pressure at 120° F. to completely empty the cylinder; and at about the same temperature seven parts of water and one of ether (the latter in this case partly going to form a layer on the surface of the water) are completely driven out. Water dissolves one-tenth its volume of ether, and the value of this addition of the highly volatile agent to it, by enabling it to penetrate cavities and permeate tissues more deeply, must be abundantly obvious.

Here let me draw attention to a fact, although it is one depending on well-known general principles—namely, that though the ether may be superheated in the cylinder, it instantaneously cools on being liberated, so that the hand can be comfortably held in the stream when the thermometer stands at 212° F. This fact may lead to some applications of importance. It shows us that we have almost any amount of diffusion power at command, and that we could easily diffuse a liquid through a cavity as extensive as the largest ovarian cyst with a comparatively small quantity of ether. It seems to me also not improbable that it may have been lost sight of in the construction of ether inhalers, and that it may enable us to devise one which will render the administration of this anæsthetic more convenient and pleasant than it is by present methods, if not also to render available anæsthetics of higher boiling points than those at present in use. I showed at the Pathological and Clinical Society of Glasgow how, by injecting an ox bladder, the liquid is diffused in the cavity by means of this injector.[2]

I have only further to mention that Dr. H. C. Cameron has already injected a hydrocele with the instrument, the solution used consisting of five grains of carbolic acid and ten minims of chloroform in three drachms of ether, which was thrown into the sac at a temperature of 120° F. As the scrotum became tolerably well inflated before the injection was completed, the operation was interrupted, and some vapour and liquid allowed to escape before the remainder in the cylinder was injected. Some liquid was again allowed to escape in the same way—perhaps, indeed, rather too much,—and, as we afterwards thought, quite unnecessarily. The result will be carefully watched and recorded.

Since the foregoing was written the injector has been used, at the suggestion of Dr. Cameron, and with a very good result, to syringe the bladder in a case of subacute cystitis, of which careful notes have been kept. I have also used it to syringe the ears, in this case driving nine parts of water by one of rhigolene, which boils at 86° F. For a vaginal douche the instrument seems to me to be well adapted, the injection of water containing one-tenth of ether at 100° or 110° (along with any antiseptic that may be thought necessary), offering a considerable advantage over ordinary methods.

[1] Subject of a paper read before the Pathological and Clinical Society of Glasgow, March 6th, 1884.

[2] A bladder suspended vertically, and capable of containing 40 oz., was injected and inflated with an ethereal solution of picric acid, and it was shown that the acid was deposited over the entire inner surface of the bladder.

ST. THOMAS'S HOSPITAL.

COMPOUND FRACTURE OF THE PATELLA INTO THE KNEE-JOINT; SUTURE OF PATELLA; RECOVERY.

(Under the care of Mr. SYDNEY JONES.)

COMPOUND fracture of the patella is not an injury of frequent occurrence, and it is important to record the treatment of those cases which do occur. On March 18th of this year a paper was read before the Harveian Society [1] on this subject, and only nineteen cases were mentioned by the reader of the paper as already on record. In cases of this injury, almost always caused by direct violence, it is usual to get more comminution of the bone than was met with in this case, and therefore the plan adopted of wiring the fragments, as for ununited fracture of the patella, is not frequently carried out. The success of the treatment in this case by wiring of the fragments and lateral drainage, with antiseptic dressing and perfect rest, will encourage to like treatment in a similar case. For the following notes we are indebted to Mr. Wheaton, dresser.

The patient (age nineteen), a healthy young man, fell forty feet down the shaft of a lift, striking the front of his right knee, which was bent up under him, against the edge of an iron girder at the bottom of the shaft. In falling he clutched the wire rope of the lift, but could not stop himself.

On admission (December 2nd, at 8.30 P.M.) there was a deep transverse wound five inches long across the front of the right knee-joint, dividing the patella completely in half and exposing the interior of the knee-joint. The patient had lost a good deal of blood and was very faint, but did not lose consciousness; there were also abrasions of the fingers and hands, and extensive bruises on the back.

The patient being under ether, Mr. Sydney Jones made a vertical incision over the front of the joint, exposing the whole of the separated fragments of the patella; it was then found that the tissues were stripped up from the lower end of the femur for some distance, but the other bones and cartilages of the joint were uninjured; the upper fragment of the patella had a clean-cut edge, but that of the lower was irregular, so that a thin slice had to be sawn from it and some loose fragments of bone removed. Two thick silver wires were then passed through holes drilled in both fragments of the patella, which were then brought accurately together; counter-openings were made on each side of the joint, and drainage-tubes inserted; the wound and incision were closed with silk and catgut sutures, and the joint dressed with iodoform gauze and salicylic wool and put up in a straight "excision" splint.

Dec. 3rd.—The patient has recovered well from the effects of the operation, and feels comfortable, but very drowsy. The temperature in the evening rose to 101·4°, when the joint was dressed antiseptically.

5th.—The temperature, which had remained at about 100°, rose to 102·2°; wound dressed, looking very well; very little discharge; no pain; patient takes milk and beef-tea well.

6th.—The patient feels feverish and thirsty; bowels confined. Temperature last night, 103°; at noon to-day, 102·6°; wound dressed; alternate sutures withdrawn; no distension of joint; no bagging; a fair amount of discharge, quite aseptic.

8th.—He complains of pain in the knee; tongue furred; bowels confined; pulse 130; temperature 100·8°; wound dressed; a good deal of superficial inflammation around it; a small collection of pus on the outer side of the patella discovered and evacuated.

12th.—Wound again dressed.

14th.—He coughed up a good deal of tenacious sputum and frothy blood; no pain in the chest; cough slight; nothing abnormal was detected in the chest. Temperature at night 101·4°. He was given five grains of sulphate of quinine three times a day.

16th.—Patient improving; another superficial collection of pus on the inner side of the patella; a good deal of discharge from the joint.

22nd.—The temperature was normal morning and evening, and the patient improving rapidly.

30th.—All the drainage-tubes withdrawn; the tibia was found to be falling back to the extent of three-quarters of an inch, and the malposition was corrected by a pad placed under its upper end.

Jan. 6th.—Antiseptic dressing left off; the wounds are now quite superficial; there is a great deal of inflammatory thickening about the joint; no pain.

Towards the end of January the temperature suddenly rose to 106°, and there was a slight rigor. A large dose of quinine was given, and it had fallen next day to normal. The joint appeared to be progressing favourably, and no complaint was made by the patient. After this time the patient gained strength rapidly, and on Feb. 15th could get about on crutches fairly well. On Feb. 20th he went out; wounds firmly cicatrised; swelling around joint subsiding; patella a little lower than normal; can be shifted laterally, but not upwards or downwards; he can flex the knee about two degrees; no abnormal lateral movement; no hyper-extension possible, the limb being quite straight; no rotation or falling back of the tibia; patient was going about well with crutches and splint; the leg became swollen a little towards evening. He was again seen on May 3rd; there was now no swelling of the leg, but no attempts had been made to flex it. He was anxious to resume work, being able to walk without stick or crutches.

LEEDS GENERAL INFIRMARY.

CASES OF COMPOUND FRACTURE.

(Under the care of Mr. MAYO ROBSON.)

THE following reports have been abstracted from notes furnished by Mr. Ashton Street.

CASE 1. *Compound Fracture of Patella, with Wound of Knee-joint; Recovery with useful joint.*—J. P——, aged thirty-five, a coachman, was kicked by a horse on the right knee on Dec. 2nd, 1885, and admitted two hours afterwards, when there was found to be a wound of 1½ in. over the front of the right patella, which was the seat of a starred fracture; a probe passed freely into the knee-joint. It was syringed well with perchloride solution (1 in 2000), and dressed antiseptically, no drainage-tube being employed; the limb was fixed on a back splint. Temperature normal throughout. Dressed for the first time on Dec. 12th, ten days after the accident, when the wound was healed. Made an out-patient Dec. 29th, plaster-of-Paris having been applied from the calf to the middle of the thigh, this being left on to steady the limb for three weeks. In March, 1886, he was quite well and able to perform his duties perfectly, the injured knee-joint moving as freely as the uninjured one.

CASE 2. *Compound Fracture of Humerus, with Wound of Shoulder-joint; Recovery with good joint.*—W. C——, aged forty, carpenter. On Dec. 3rd, 1885, while at work, a circular saw broke in two and one half struck his shoulder, knocking him down. When admitted to the infirmary a few hours afterwards, there was found to be a large wound of about seven inches reaching from the tip of the acromion down the arm through the deltoid. The shoulder-joint was laid open, the tip of the acromion was cut off, and the upper end of the humerus was the seat of a severe comminuted fracture. All the parts were thoroughly cleansed and then syringed with perchloride lotion (1 in 2000); two drainage-tubes were inserted, and the wound was brought together with catgut sutures. The arm was fixed to the side with the hand across the chest. The wound progressed favourably, and on Jan. 19th, when it had nearly healed, the arm was freed from its bandages and he was allowed to return home. On March 28th the patient reported himself, with the wound healed and with good movements in the joint, he being able to raise his arm above his head, and to rotate it freely and to place his hand behind his back.

CASE 3. *Compound Dislocation of Left Astragalus, with Fracture; Recovery, with useful joint.*—J. S——, aged thirty-one, a miner, was run over by a waggon and admitted

Digitized by Google

to the infirmary within a few hours of the accident with a wound over the inner ankle running from the anterior border of the internal malleolus round the back of the heel to the outer border of the tendo Achillis; through the wound the astragalus was protruded. The internal lateral ligament was but slightly injured, and on this, as a hinge, the astragalus was turned with its upper surface downwards, having been completely torn away from the external lateral ligament; the outer articular surface was broken, but there was no fracture of the malleoli. The flexor longus pollicis tendon was torn from its muscle and had to be removed; the posterior tibial artery was torn, though not bleeding, but the nerve was not injured. After enlarging the wound, the astragalus was separated from its attachments and removed, and the wound was then well syringed with perchloride solution, a large drainage-tube being inserted. It was dressed antiseptically and put up on an anterior wire splint. The wound, which was in a very dirty condition when he was brought in, was evidently not fully asepticised, for it suppurated, and the matter collecting by the side of the tendo Achillis had to be let out by incision. He made a slow recovery, and was discharged on Feb. 5th with a limb which promised to become a very useful member.

CASE 4. *Compound Fracture of Humerus, with Split Fracture into Elbow-joint; Recovery with freely movable joint.*—A. B——, aged ten, a schoolboy, was admitted on July 16th, 1885, six hours after being thrown down by a companion, when there was found to be a wound of 1½ in. in front of the lower end of the humerus just above the flexure of the elbow, communicating with a very loose split fracture opening the elbow-joint, the muscles being much torn. The wound was syringed with perchloride lotion, and dressed antiseptically, a drainage-tube being inserted. The limb was placed on an internal rectangular splint. He was made an out-patient on Aug. 11th, with the wound almost healed, but with much callus around the seat of fracture, impeding the movements in the elbow. The splint was left off five weeks after the accident, and friction and passive movements employed. When seen in February, 1886, all the movements of the joint were very good. He had no pain, and the fracture was quite sound.

Remarks by Mr. MAYO ROBSON.—Before the introduction of antiseptic surgery such injuries would probably have required primary amputation; or even, if at considerable risk to life attempts had been made to save the limbs, suppuration must have occurred in and around the articulations leading to ankylosis, if not necessitating secondary amputation. The chief difficulty is in rendering wounds of this nature aseptic, since the skin is as a rule greasy and dirty, and the muscles and bones are often covered with grit and foreign matters. To effect this the skin is well rubbed with turpentine, which removes the grease and renders it clean and aseptic; and after all foreign matters have been picked out, or if needful scrubbed away by means of a brush, the wound is very freely syringed out over and over again with perchloride lotion (1 in 2000) by means of a Higginson's syringe. A drainage-tube and sutures having been inserted if needful, the wound is covered with a single layer of gauze soaked with perchloride lotion, and over this dry dressings of salicylic wool or silk are applied, the chief guiding principles in the after-treatment being infrequent dressings and fixation of the limb until healing has taken place, after which friction and passive movements help to restore impaired functions.

TIMARU HOSPITAL, NEW ZEALAND.

TWO CASES OF COMPOUND DEPRESSED FRACTURE OF THE VAULT OF THE SKULL; TREPHINING; RECOVERY; REMARKS.

(Under the care of Mr. H. V. DREW.)

CASE 1.—Alex. D——, aged forty-two, a farmer, was admitted on Feb. 15th, 1885. When seen, a few minutes after admission, he was sitting up in bed and quite sensible. He nodded and smiled when spoken to, and in answer to questions said that a heavy horse had reared, and in coming down had struck him on the head with one of his fore-feet, which stunned him for a few minutes, and when he tried to get up he found himself paralysed all down the right side. On removing the dressing from his head a pulsating area the size of half-a-crown was visible, and on examination under chloroform, which was kindly administered by Dr. Hogg, the bone was found to be sunk right into the brain, the same having "welled up" over it. Not being able to remove the bone, Mr. Drew used a small trephine at the extreme margin of the fracture, which enabled him to remove all the fragments—also about half an ounce of brain matter, as near as could be judged, this being completely disorganised. All foreign matter, clots, &c., having been removed and the wound washed out gently with a 1 in 40 carbolic solution, the scalp was laid down without sutures of any sort, a piece of Lister's protective covering the wound; over this was placed a piece of lint wrung out in a 1 in 40 carbolic solution, and then a piece of iodoform wool, with one layer of bandage under the chin and over the head to keep things in their place. Irrigation with a 1 in 40 carbolic iced solution was resorted to, but this had to give way to rectified spirit lotion, as symptoms of carbolic poisoning began to manifest themselves. The patient did not vomit at all. His food consisted of iced milk and chicken broth, with bread later on, and the only medicine he had was an occasional dose of calomel. On the thirteenth day he could flex his previously paralysed leg; on the twenty-fifth day he could extend the same. On the twenty-seventh day he began to recover the use of his arm (flexion only), and on the thirtieth day he could extend the same, though he had not yet recovered the power of pronation or supination. On the thirty-second day he had a bilious attack, and his temperature rose to 101° F. and his pulse to 150, but fortunately by the use of calomel both were reduced in forty-eight hours to normal.

The patient during this attack never vomited in the ordinary acceptance of the word, for he has the power to cause his food to regurgitate at will; and by so doing he avoided the risk which forcible vomiting might have caused him to incur. At the end of eight weeks the patient had recovered all the movements of his arm and leg. The wound had long since healed, though a pulsating area about the size of half-a-crown is visible. The injury was seated over the ascending parietal convolution, and lobule of same (left) as near as could be judged. The wound was perfectly antiseptic, though Lister's dressing could not be accurately adhered to. The wound was dressed every day under a continuous dripping of 1 in 40 carbolic. No sutures were employed, accurate union was effected, and the wound was left alone. The temperature never rose above 99° F., except during the bilious attack. The recovery of flexion before extension of each limb is noteworthy, also the later return of the more complex movements. Slight bagging of the scalp at the back of the head was noticed, presumably due to the escape of subarachnoid fluid, but was soon completely absorbed. The pulse fluctuated between 50 and 90 (except during the bilious attack), and the greatest difficulty met with in conducting the case was the regulation of the bowels. In February last the patient was still well, and was doing hard work.

CASE 2.—John L——, aged forty-five, nurseryman, was admitted on Jan. 2nd, 1886, suffering from the effects of a blow from a 16 lb. hammer, received at the Caledonian Sports. On admission he was found to be conscious and suffering somewhat from shock and a lacerated wound found over the right frontal bone, the greater part of the latter being depressed. The fracture was very extensive, and there was bleeding from the nose, the right eyelid being very tense from extravasation of blood. Dr. Hayes of Temaka was with Mr. Drew at the time, and kindly assisted; and as he agreed as to the advisability of trephining, the operation was at once proceeded with. A small piece was removed with the trephine, and then the large depressed part was raised, and, after some little difficulty, kept in position. The skull was found to be excessively thick (three-eighths of an inch). The scalp was laid down when the bleeding had ceased, and silver sutures were used to unite the incised portion of the wound, the posterior or lacerated part being left open and a small drainage-tube inserted. The wound was dressed as in Case 1, and the patient put upon a clean bed. Towards the end of the operation the patient vomited a large quantity of altered blood, and the vomiting of blood continued throughout the night in spite of sucking ice.

Next day the wound was dressed as before, and the tube cleaned and replaced; no depression was noticeable, and things looked well; pulse 60; temperature 98° F. No vomiting occurred after this. A little milk-and-water (iced) and a little thin gruel were taken. Evening temperature 99·4°. The patient remembered nothing about being brought in or about the operation, though he spoke quite rationally at the

Digitized by Google

time. He sees "double," and is completely deaf on the right side; has numbness of skin of forehead, and complete loss of sensation over the area of distribution of the infra-orbital nerve, also of the right lower part of face; his taste is also much affected. Mr. Drew therefore concluded that taken with the vomiting of blood that he had a fracture of the base, as well as the fracture described.

On the sixth day the sutures were completely removed, and on the seventh day the drainage-tube, which had been shortened from time to time. On the twenty-seventh day the patient was sitting up in bed, the wound having been healed for some days. The highest temperature was 99·8° F. on the seventh day, and has since been normal. Hearing has returned, taste and sensation of skin of face much improved, and vision is normal. Patient feels as well as before the accident, and there is no mental or physical defect. He left the hospital on Feb. 2nd, 1886, exactly one month after admission.

Remarks by Mr. DREW.—I attribute the successful results in these two cases, both of which were of extreme severity, and both only forty-two years of age, to the following causes: Symptoms were not waited for, but both patients were immediately trephined; depressed bone was known to exist, and though if left it *might not* cause symptoms, if elevated or removed it *could not*. The ordinary Listerian dressing was not used, as it was feared that the bandaging &c. would not conduce to coolness, and the pressure would have been injurious; but by applying the dressing as described in Case 1, and redressing every day without interfering with the wound, and under a constant dripping of weak carbolic lotion, the same principle was adhered to with precision. Very great care was observed with the food, very little being given for the first week; no friends were admitted for a fortnight, and the patients were kept perfectly quiet in a well-ventilated room and in a subdued light, and the bowels were carefully regulated every third day. The cold lotion undoubtedly retarded the healing process, but this was more than counterbalanced by the immunity from risk of inflammation of brain it ensured, and also the freedom from pain or even discomfort of the patient. I wish to acknowledge my obligation to Drs. Hayes, Hogg, MacIntyre, and Longrove for their kind assistance.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Obliterative Tracheitis and Bronchitis in Congenital Syphilis.—Pathological Histology of Hydrophobia.—Granuloma Fungoides.—Hepatic Abscess secondary to Pelvic Inflammation.—Primary Cancer of Thyroid.—Double Intestinal Stricture.—Spinal Abscess, destroying Kidney and opening into Duodenum.—Psoas Abscess, with formation of New Bone in Sinus.—Tubercular Arteritis.—Malignant Growth of Lip, with Melanosis.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair. The meeting began half an hour earlier than usual. As the executive are endeavouring to complete the work of the session, the next and last meeting is also to commence at 8 instead of 8.30 P.M.

Mr. R. W. PARKER showed specimens of a case of Obliterative Endo-tracheitis and Bronchitis. They were removed from the body of a boy aged fifteen years, the subject of congenital syphilis. He had first came under observation on account of endosteal nodes on both tibiæ, and of a tracheal fistula dating back three or four years, when he was tracheotomised for syphilitic laryngitis by Mr. Elkington of Birmingham. He continued to wear a tube for many months; on its withdrawal the opening had remained patent. It was thought not improbable that the irritation of fine foreign matter (dust, &c.) entering the lungs through this fistula had first started the condition about to be described. Commencing about an inch above the bifurcation, the lumen of the trachea suddenly began to narrow in a more or less uniform manner; a little lower down this narrowing became less uniform but more marked, so that the lumen was reduced to about one-third of its normal size. The left bronchus was almost entirely occluded. The occluding new growth consisted of well-formed fibrous tissue surrounding and separating the mucous glands, which appeared quite healthy. The changes in the trachea were strictly endo-tracheal; those in the bronchi were partly endo-bronchial and partly peri-bronchial, the latter, it was thought, being secondary to interstitial pneumonia set up by the retained secretions. Both lungs were in an advanced state of bronchiectasis. The extent of the occlusion of the lowest part of the trachea and of the primary bronchi was very remarkable, the available area for breathing purposes being little more than that of a large quill. The resemblance of this condition to endarteritis was remarked upon. In reply to Dr. Bristowe, Mr. Parker said that, so far as he knew tracheotomy did not lead to cirrhosis of the lung.

Dr. HALE WHITE showed a series of specimens illustrating the Pathological Histology of Hydrophobia from two men and one dog. The medulla oblongata was in a state of acute inflammation, for the most part limited to the floor of the fourth ventricle and the subjacent nerve-tissue for a depth of about one-third of the thickness of the medulla. It was most marked in the median line on either side of the posterior median fissure. The result of this inflammation was a general blurring of the nerve tissue, so that the normal arrangement of fibres and cells could not be made out; there were many small inflammatory cells in tissue, and under a high power of the microscope they could be seen in large numbers crowding through the walls of the vessels. The inflammatory exudation had a tendency to run in directions determined by the nerve fibres. The nerve cells were implicated, and in many places blurred and indistinct; the nuclei most affected were the vagal and hypoglossal. The dilatation of the minute vessels was extreme, and had in many cases led to their rupture; the hæmorrhages thus produced were all microscopic, and were most numerous immediately under the floor of the ventricle, so that blood could often be seen to be effused into the meshes of the pia mater, but in no place was this membrane itself ruptured. The same condition was observable in other parts of the brain, but to a much less degree, and it could be also seen in the cord to a slight extent. Thus, it will be gathered that the essential lesion in hydrophobia is an acute inflammation of the floor of the fourth ventricle, and that this spreads slightly upwards to the brain and downwards to the cord. In the salivary gland there was some blurring of the secretory epithelium, and a few leucocytes could be seen wandering about among the gland constituents. In one case there was an atrophic condition of the thyroid gland. The vagus and sympathetic nerves and every organ in the body were examined, but they were all found to be healthy with the exceptions just mentioned.

Dr. PAYNE showed drawings and microscopic specimens of Granuloma Fungoides from a man aged fifty-six. The cutaneous affection consisted of scattered, large, red, scaly patches, which became dark red and then brown, and looked like psoriasis or scaly eczema; but, in addition, there were, sometimes replacing the patches, tumours of hemispherical shape, from half a walnut to an orange in size. The man was born in the country, but had passed thirty years in London at a railway station. The diagnosis presented some difficulty, and leprosy was thought of. It was, however, like that described by Alibert as mycosis fungoides, and by others as lympho-sarcoma and general sarcomatosis. A case was recorded under the name of leprosy in the twentieth volume of the Transactions which Dr. Payne regarded as a granuloma fungoides. The internal organs were healthy. The tumours only invaded the skin, and consisted of an infiltration of small round cells, which had essentially the same structure as that of the scaly patches; there was also some evidence of a new formation of connective tissue without giant cells; the structure was not specially lymphatic, and the cells differed from those of sarcomata. Micrococci had been described by Auspitz of Vienna as a copious infiltration of the cells; but the evidence of their nature was not conclusive. Rindfleisch had discovered an undoubted streptococcus, but only within the vessels; these were certainly not present in Dr. Payne's specimens. The foreign observations being post-mortem specimens, the presence of micrococci could be easily accounted for.

Mr. F. S. EVE showed a specimen of Granuloma Fungoides of the Foot. It was limited to the skin and projected from the dorsal surface of the foot; a warty condition existed along the inner margin of the growth, and this papillary condition extended nearly up to the knee. The patient was a man aged fifty-three, a merchant, who had had cardiac disease and albuminuria for many years. There had been

Digitized by Google

lupoid-like growths on the left leg, which had left scars and a kind of spurious hypertrophy of the tissues. As the growth was considered to have become epitheliomatous, amputation of the limb was performed, and the patient made a good recovery. Later on a tumour appeared at the upper part of the right forearm, but this sloughed, and cicatrisation ensued; it was regarded as an intermuscular specific gumma by Mr. Hulke. In the buttock also a dense white firm tumour appeared, and exposed the ilium, which became partly necrosed. A sister of the patient showed signs of congenital syphilis. There were many differences from ordinary gumma in the tumour shown, the fibrous tissue being so abundant. As described by Auspitz, and obtained by Gram's method, there were many cells that stained blue in a remarkable way, but this was not due to micrococci.—The PRESIDENT did not think that Mr. Eve's specimen was of the same nature as the first. Dr. T. ACLAND said that Mr. Ballance and himself had been unable by cultivation experiments to demonstrate the existence of any micro-organism. If these were present the outline of the cells would not be so perfect.—Mr. JONATHAN HUTCHINSON, jun., alluded to the case of supposed actinomycosis described by Mr. Treves; his father had a somewhat similar case at the London Hospital, in which the skin alone was involved with lupoid-like growths.—Dr. PAYNE replied that the stained points had nothing to do with nuclei in his sections; they were probably albuminoid granules, and related to vital processes, for they disappeared after death.—Mr. EVE said that in Auspitz's case a scaly eczema preceded the formation of the growth for seven years. He had detected the same kind of cells in syphilitic growths.

Dr. HANDFORD showed specimens of Hepatic Suppuration, probably due to pelvic suppuration, in a woman aged twenty-five, who had led an immoral life. Much pyrexia, cough, diarrhœa, and rigors were the chief clinical signs. The liver was very large and tender, but aspiration failed to strike pus. The necropsy showed a large extent of suppuration in the right lobe of the liver, which weighed 10lb. 6oz. The lobe was honeycombed in all directions, and around this many scattered pea-sized areas of abscesses were detected. There was no sign of hydatid. The spleen weighed 13oz., and the kidneys were much enlarged and flabby. There were abscesses in the caudate nucleus, and one damaged the anterior limb of the internal capsule, but caused no definite symptoms. The Fallopian tubes were distended with curdy purulent fluid. The sigmoid flexure was bound down to the back of the uterine fundus. The sequence of events was probably gonorrhœa, double pyo-salpinx, and pyæmia. In a case recently reported by Mr. Bilton Pollard the sequence of events was gonorrhœa, thrombosis of iliac veins, suppuration of hip-joint, thrombosis of pulmonary artery, and death.—Mr. STEPHEN PAGET said that from certain statistics of 400 cases of pyæmia he had come to the conclusion that the lymphatics had a large share in the distribution and arrangement of the lesions of pyæmia; and Dr. Tilt had published a paper in the Obstetrical Transactions on the importance of lymphangitis in pelvic pathology. The chances of the liver being affected if the bone were the seat of the lesion from which pyæmia developed were one in four, whereas if the bone were not involved the chances were one in twenty. He thought the lymphatic tissues were operative in this connexion, and not the veins, for in twenty cases of pyæmia after venesection only one had hepatic abscess, and that was where it had been performed for acute secondary syphilis.—Dr. S. WILKS considered that pyo-salpinx was a source of danger; in one he had seen brain disease follow, and in another septic pleuro-pneumonia. Morgagni had noticed that certain cases of Fallopian abscess followed gonorrhœa, and were a cause of sterility.—Dr. HADDEN said the description of the liver reminded him of actinomycosis. Had the author taken that view into consideration?—Dr. CARRINGTON said that the portal vein was healthy in instances of tropical abscess that he had seen. The lymphatics probably conveyed the contagium.—Dr. N. MOORE corroborated this view. In only one case had he seen the portal vein diseased.—Dr. HANDFORD had not specially examined for the actinomyces.—The specimen is to be investigated by Drs. Hadden and T. Acland.

Dr. NORMAN MOORE exhibited a specimen of Primary Carcinoma of the Thyroid from a woman aged forty-six, lately under his care in St. Bartholomew's Hospital. The new growth formed a huge mass, which had ulcerated through the skin and into the larynx. It completely compressed one recurrent laryngeal nerve, and pressed on both carotid arteries, and had grown through the upper wall of the arch of the aorta, but without causing extravasation of blood. Secondary deposits were found in the kidneys, on one rib, and in the brain. All the deposits showed great mixture of cells, but in them were groups of well-marked epithelial type, surrounded by numerous connective tissue cells, but with a very ill-developed stroma. The growth seemed to be of epithelial type, probably originating in the walls of the loculi of the thyroid. The duration of the growth was about four months. On the patient's admission to the hospital a large cyst projected from the right lobe, and from this blood-stained fluid was let out, but it rapidly refilled. After a month in the hospital the tumour began to approach the surface, and broke through in a few days as a fungating mass. There was some dysphagia and partial aphonia, but never urgent dyspnœa.—Dr. F. SEMON said malignant growths of the thyroid gland were by no means so rare as was supposed; at least a dozen had been recorded in the past year.—Mr. SUTTON said there were no theoretical objections to the development of cancer in the thyroid gland, for it was of hypoblastic origin.—The specimen was referred to the Morbid Growths Committee.

Dr. CARRINGTON brought forward two cases of Double Stricture of the Intestine. The first was in a man aged forty-nine, who was admitted into Guy's Hospital on Dec. 28th, 1885, under the care of Mr. Bryant. The history was, briefly, that since the previous August he had suffered from griping abdominal pain and obstinate constipation. A mass of growth could be readily felt per anum. Colotomy was performed in two stages, but the operation afforded him no relief, and he died on Jan. 6th. At the necropsy a well-marked cancerous growth with thick everted nodular edges and ulcerated surface was found four inches up the rectum. The stricture was very tight. A second growth with the same characters was found surrounding the ileo-cæcal orifice. No secondary nodules were found in the body. The second case was more complicated, but presented the feature of a double intestinal stricture. The patient was a female aged sixty-one, and was admitted on Oct. 10th, 1885, much wasted and careworn and deeply jaundiced. The illness had commenced ten months before by abdominal pain. She became jaundiced on Sept. 28th. She was obstinately constipated throughout, but only vomited on two occasions—viz., Oct. 10th and 11th. With the exception of a nodule in the tissues surrounding the umbilicus, which was thought to be cancerous, no objective cause of the jaundice was discovered. The viscera on admission all appeared to be healthy. On Dec. 25th the pain became much intensified and the abdomen very tender, and she died the next day. On opening the abdomen fæcal extravasation and acute peritonitis were discovered. The bowel had given way just above the uppermost of two strictures, which were situated three feet above and one foot below the cæcum respectively. The strictures were quite narrow and annular, triangular on section, with the bases on the peritoneal surface. There was scarcely any lumen to the bowel at the upper stricture, and the calibre of the colon at the site of the lower one was certainly not more than half an inch. The gall-bladder contained two faceted gall-stones. The common bile-duct was surrounded by a nodule of growth of the size of a walnut, which had invaded the liver by continuity. The liver weighed 32 oz., and contained a few secondary nodules. There was much thickening and puckering in the portal fissure. The ovaries contained one or two small nodules. No other disease was found.

Mr. DAVIES-COLLEY exhibited the Lumbar Spine, with the Right Kidney and the Duodenum, of a woman aged twenty-four, who had come under his care in Guy's Hospital with angular curvature of the lumbar vertebræ, accompanied by excessive pain in the right lumbar and iliac regions and in the upper part of the right thigh, but without any distinct fluctuating swelling. Under an anæsthetic a lumbar incision was made, and the side of the body of the third lumbar vertebra exposed. Nothing flowed at the time, but in the evening there was a free discharge of foul and turbid pus. No relief of the pain followed. The copious suppuration continued, and was thought to be stercoraceous. In eleven days the patient died, and was found to have extensive disease of the last lumbar vertebra, and, to a slight extent, of the fourth. The right kidney was disorganised, and there was a perforation of the second portion of the duodenum just below the entrance of the common bile-duct. The chief points of interest in the case were: 1. The want of correspondence of the angular projection, which was formed by the spine of the second, third, and fourth lumbar

Digitized by Google

vertebræ, with the disease, which had utterly destroyed the body of the fifth and only slightly attacked the fourth lumbar vertebra. 2. The absence of any pus in the urine to indicate the destructive process going on in the kidneys. This was probably due to the occlusion of the ureter having preceded the renal suppuration. 3. The remarkable clinical results due to the perforation of the duodenum. The suppurating cavity appears to have discharged itself by the opening, and in consequence there was no fluctuating swelling in the usual sites of spinal abscess. At the same time, excruciating pain was set up by the food getting into the abscess cavity. This still continued after the operation, and probably the escape of the food through the wound increased the weakness of the patient.

Dr. A. Q. SILCOCK showed a Psoas Abscess with formation of new bone in the wall of the sinus, taken from a child aged five. The psoas abscess was right-sided, and in the wall of the sinus were plates of bone of spurious nature, the canalicular systems not being properly developed. Perhaps the liability to formation of bone in the tendon of the psoas, the quantity of lime salt passing by, and the tendency of chronic inflammation to form bone, were sufficient reasons for the development of the bony plates.—Mr. SHATTOCK raised the question of actinomycosis in Mr. Davies-Colley's case. The communication of the duodenum with the cavity of the abscess reminded him of the description by Israel of cases of primary infection of the intestines with secondary caries of the spine.—Dr. CARRINGTON said that the perforation of the duodenum was so obviously recent that Mr. Shattock could not hold the actinomycotic view if he had been present at the necropsy.—Mr. DAVIES-COLLEY replied in the same strain.

Dr. C. TURNER showed a specimen of Aneurysm of a branch of the Pulmonary Artery in an old cavity in the Apex of the Left Lung, from which rapidly fatal hæmorrhage had occurred. In the lung were also several wedge-shaped masses of recent consolidation and old fibroid areas. The specimens were obtained from a child aged six, who had suffered from pulmonary symptoms for two years and a half since an attack of measles. She had been failing in health for twelve months, and had had occasional attacks of hæmoptysis. She had not been laid up until four months before her death. She improved under treatment, but the symptoms returned with progressive severity a few weeks before death occurred from profuse hæmorrhage, of which there had been no warning. Sections from the neighbourhood of the cavity show great proliferative thickening of the inner coat of the pulmonary arterioles in and adjacent to caseous tracts, and much nuclear infiltration and proliferation of the outer coat of the arterioles and of the interlobular and interalveolar connective tissue, and of that around the caseous tracts and nodules, which contain many giant cells of the kind seen in tubercular lesions. A button-like elevation, which appeared to be another small aneurysmal bulging on a branch of the pulmonary artery, was to be seen in the wall of the cavity near the first. The specimen was regarded as an instance of rupture, and possibly of the formation of such aneurysms as were incidental complications of a progressive phase of a chronic pulmonary lesion, attributable to weakening of the walls of the pulmonary arterioles by peri-arteritis, unattended by obstructive endarteritis of corresponding degree, such as might have produced the cavity and wedges of consolidation and fibroid induration seen in the lungs. The right lung was completely fibrous and retracted. There were cavities in the upper lobe, but no miliary tubercles in the lungs or abdominal viscera. The child's paternal grandparents had both died young, but there was no other evidence of phthisis in the family.

Dr. F. W. MOTT exhibited a specimen of Malignant Melanotic Growth of the Lip from a single woman, aged thirty-seven. It had grown from the upper lip for two weeks when first seen, and had a purplish aspect, softened in the centre and hard at the periphery; no pulsation or induration. The mucous membrane was unaffected. After six weeks the growth was removed, having attained the size of a walnut, by a V-shaped incision. At the end of ten weeks the right cheek and right submaxillary gland were involved with new growths, and another nodule appeared behind the right ear. In four months the scar showed signs of recurrence and the left submaxillary gland became involved. Later still, a fresh nodule appeared to the left of the occipital protuberance; the patient became deaf first on the right and then on the left side. Hæmorrhage frequently recurred, and she died exhausted by it at the end of one year and ten months from the first appearance of the growth. The internal organs were healthy. The situation of the primary growth in the lip was rare; the disease had only spread locally; it was either an alveolar sarcoma with melanosis, or a specimen of carcinoma melanodes with much pigmented fibro-vascular stroma. Kaposi had described such tumours as commencing in buccal glands.

The following card specimens were shown:—Dr. Payne: Trichorexis Nodosa. Dr. Sherrington: Spinal Cord from a case of Friedreich's Hereditary Ataxia. Mr. Ballance: Calvaria showing perforations from a case of Hydrocephalus. Mr. Shattock: Calvaria perforated and ridged in Meningo-encephalocele. Dr. N. Moore: Case of Hydrocephalus. Dr. Handford: Aneurysm of Aorta communicating with Pulmonary Artery. Mr. Eve: Multilocular Cyst of Epididymis. Mr. E. H. Fenwick: Villous Tumour of Bladder. Mr. Churchill: Central Sequestrum of Great Trochanter from a case of Hip Disease. Mr. Targett: Traumatic Hernia through Diaphragm. Mr. Stoker: Cancer of Thyroid. Mr. J. Poland: Old Subcoracoid Dislocation of Shoulder.

CLINICAL SOCIETY OF LONDON.

Interstitial or Subpleural Laceration of the Lung.—Gummata of the Liver.—Hydatids of Liver opening into Right Lung.—Resection of Knee for old-standing Ununited Fracture of Patella.

AN ordinary meeting of this Society was held on the 30th ult., Dr. Cayley, Vice-President, in the chair.

Mr. TIMOTHY HOLMES read a case of Subpleural Laceration of the Lung in a girl aged fourteen years, who had fallen and severely bruised the right breast. There was no fracture of the ribs. The leading symptoms were hæmoptysis, great dyspnœa, and entire absence of breathing in the right lung. The right chest did not move in respiration; it was natural on percussion. These symptoms, with the history of her having a piece of biscuit in her mouth at the time of the accident, led to some suspicion of the impaction of a fragment in the right bronchus; but the progress of the case negatived this idea. The dyspnœa was at first so alarming that tracheotomy almost seemed indicated. Next day, amphoric breathing was heard under the angle of the right scapula, and this soon developed into the physical signs of a large cavity in the lung, but without any sign of fluid or air in the pleura. This cavity gradually contracted and the girl quite recovered. It is noteworthy that subcutaneous emphysema appeared at the right side of the root of the neck on the third day. When last seen, the girl, though in perfect health, had evident physical signs of considerable consolidation of the right lung. In commenting on this case, the author quoted Nélaton's description of the symptoms of subpleural laceration (including emphysema at the root of the neck) as exactly verified by the symptoms here observed. He remarked on the slight attention which was bestowed on this form of injury in most of our text-books, and the doubts which he had himself expressed in his own work as to the possibility of diagnosing the subpleural form of laceration. These considerations, together with the comparative rarity of such cases, would, he believed, justify the publication of this case; but it also contained a feature of its own, which had not hitherto been noticed in the history of the lesion—viz., the entire suspension of respiration in the injured lung. The cause of this phenomenon was discussed, and reference was made to other cases of subpleural laceration.—Mr. A. T. NORTON alluded to a similar case that occurred in a man who was by accident completely buried under a load of sand. There was gurgling and copious hæmorrhage, with pneumonic symptoms, but no pleural signs.—Mr. R. J. GODLEE referred to a specimen shown by him at the Pathological Society some years ago, in which a main bronchus had been torn completely across; could such an accident have happened in Mr. Holmes's case?—Dr. J. S. BRISTOWE suggested that there might have been a pneumothorax if there were perfect metallic tinkling and absence of breath sound.—Mr. T. HOLMES said that there was no question as to there being nothing in the pleural cavity. As the result of laceration of the lung a cavity formed gradually, and gave rise to the physical signs mentioned in the description. He believed that the laceration had involved the tissue of the lung, and not a bronchus. On recovery the lower part of the lung was solid from cicatricial processes. The subcutaneous emphysema was so limited, and only came on at the third

Digitized by Google

day, that he believed it could not be due to rupture of a large bronchial tube. The absence of breath sounds was remarkable and difficult of explanation, except on the theory that a large bronchus was obstructed by blood clots.

Dr. BRISTOWE read the notes of a case of Gummata of the Liver, in a boy aged fifteen. The patient was admitted into St. Thomas's Hospital with a tumour in the epigastrium, from symptoms of which he had suffered for six months. The tumour was about as large as a Tangerine orange, and slightly tender. The boy looked healthy; and as no history of syphilis was obtained, and no indications of congenital syphilis were observed, the suspicion that the case was one of visceral syphilis was dismissed. No definite opinion, however, was formed as to the nature of the disease; but on two occasions a fine trocar and cannula were introduced, with the result that they simply penetrated solid matter. The boy remained in the hospital for four months without specific treatment, and with gradual enlargement of the liver, and during the whole of this time presented a hectic temperature (the morning fall being down to the normal or even below it, and the evening rise varying from 101° to 103°) with frequent chills or slight rigors. But his general health remained apparently unimpaired; he did not lose either flesh or strength, he had a good appetite, and slept well. At the end of the four months, a closer inquiry elicited the facts that three of his brothers and sisters had died in infancy; that he had himself, when seven years old, suffered for several months from some affection of his eyes; and that, what had hitherto been overlooked, there were several very faint nebulæ in both corneæ. There was no trace of congenital syphilis. Acting on this information, Dr. Bristowe at once treated the patient with iodide of potassium and mercury. On the fifth day of treatment the morning and evening temperature were both subnormal for the first time; and from this time onwards (with two or three exceptions, when it rose to 98·4° or 98·6°, and one, when under the influence of an attack of tonsillitis, it rose to 102·6°) the morning and evening temperatures remained subnormal until, at the end of two months, he left the hospital. Under the anti-syphilitic treatment the liver diminished in size, all pain and tenderness ceased, and he gained flesh. Excepting for some remaining tumour of the liver, the patient left the hospital apparently well six months from the time of admission.—Dr. CAYLEY had seen a case in an adult where there was rapid enlargement of the liver in the epigastric region associated with considerable enlargement of the spleen; rigors and pyrexia led him to think of suppuration or suppurating hydatid. An incision made by Mr. Hulke detected no pus, and the man ultimately recovered.—Dr. S. P. PHILLIPS said that the intermittent pyrexia had been recognised as occurring in tertiary syphilis by Murchison in a lecture published in THE LANCET about ten years ago.—Dr. BRISTOWE, in reply, asked whether Dr. Cayley's case had been treated specifically.—Dr. CAYLEY replied that it had, but did not seem to improve as the result of it.—Dr. BRISTOWE then ventured to think that Dr. Phillips' remarks had no bearing on his case, for it was not a pyrexia like that of intermittent fever, but a genuine morning fall and evening rise such as occurred in hectic states. He had seen many cases of gummata of the liver, but none in which such a temperature chart obtained. He was aware that intermittent fever had been observed in certain cases of syphilis; indeed, he reported examples of it to the Society some years ago.

Dr. R. W. BURNET read a case of Hydatids of the Liver opening into the Lung, excavating the lower lobe of the right lung. The patient, aged thirty, was admitted into the Great Northern Central Hospital on Sept 18th, 1885, complaining of pain in the right hypochondriac and epigastric regions radiating into the right axilla and right shoulder, and of sickness and vomiting, which occurred without any special relation to the taking of food. The vomited matter was described as being greenish-yellow; she had never brought up blood, and after being sick always felt relieved. She had been losing flesh rapidly. On admission she was anæmic and weak, with an anxious expression of face; tongue red and irritable; temperature 101°; urine dark, acid, sp. gr. 1020, and containing a trace of albumen. On examining the chest, the heart's impulse, diffused and feeble, was seen and felt about or slightly outside the normal position. Cardiac dulness commenced on a level with the nipple and was lost in abdominal dulness. Dulness extended from the fourth rib downwards in front, while behind it commenced at the fifth rib and increased towards the base, where it was absolute. Breath sounds were feeble in front, somewhat harsh posteriorly, and accompanied by a few large crepitations; at the base they were feeble, and not tubular. The left side was fairly normal throughout. The lower part of the abdomen was flaccid, and not tender on pressure; but all over the right hypochondriac, epigastric, and left hypochondriac regions there was no marked tenderness. On the right side there was evident bulging. Dulness was present in the hepatic region from the level of the nipple to one inch above the umbilicus, and continued into the right axilla, epigastrium, and lower third of the left axilla. The patient had never been strong, but there was no history of definite illness until three months before admission, at which time she was slightly jaundiced, and began to suffer from pain in the abdomen, with retching and vomiting. Shortly after she came into hospital the patient was examined under chloroform, and a consultation held with a view to surgical interference, but it was deemed inexpedient to operate. On October 14th, after severe coughing, she brought up a quantity of purulent fluid, and ten days later more of the same fluid and some undoubted hydatid cysts; microscopic examination showed pus, cholesterine crystals, and hooklets. On November 23rd another very severe fit of coughing was followed by expectoration of a large quantity of cysts and pinkish purulent fluid—in all, five pints. The physical signs then considerably altered, the dulness diminished greatly in area, and feeble breath sounds were heard at the right base, but no moist sounds. The patient sank and died on Dec. 10th. At the necropsy firm adhesions united the lower two-thirds of the right lung to the parietes and to the diaphragm; the whole lower lobe of the right lung was excavated and formed a ragged cavity lined with lymph, but with no trace of true hydatid membrane; between this and the liver there was a thick layer of fibroid tissue, with an opening through the diaphragm into the liver; in the liver was a small cavity, and within the cavity a plate of partially calcareous material, bile-stained, and adherent to the wall. Dr. Burnet remarked on (1) the obscurity of symptoms when the patient came into hospital; (2) the absence of any lengthened history of previous symptoms; (3) the question, Could a diagnosis have been definitely arrived at before the appearance of the cysts? (4) what operative interference, if any, should have been adopted.—Mr. HARRISON CRIPPS raised the surgical question of the treatment of hydatid tumours of the liver. In one case he used a trocar and cannula, and then drained by means of catheters left in for months together. In another he employed a fine trocar and cannula; this case suppurated, but only aspiration was afterwards performed. The third case was operated on by incision and total removal of two large hydatid cysts through the wound. All the cases were completely successful.—Dr. F. TAYLOR understood that Dr. Burnet's paper dealt with the question of treatment of hydatid cyst presenting itself in the chest, and not in the abdomen. He narrated an interesting case where the liver was greatly enlarged, with displacement of the heart, whose apex beat was felt in the third intercostal space; considerable dulness was detected in both backs. A puncture was made at the left base and forty ounces of bile-stained fluid withdrawn; at a second puncture a similar quantity was obtained. But nothing was obtained by aspirating over the enlarged liver. A puncture of the right base yielded fifty ounces of hydatid fluid. It was not till this time that the diagnosis was confirmed. Pleurisy and exhaustion led to death. The necropsy revealed a huge cyst in the right side of the chest, and a secondary collection of fluid had displaced the heart.—Mr. R. J. GODLEE did not perceive what treatment could have been adopted before the diagnosis had been made; afterwards incision and drainage might have proved effective. He related one case in which lung and pleura had been ruptured; a large escape of bile-stained fluid followed incision, and though death occurred long afterwards, there was nothing left but a narrow fistulous track.—Dr. J. S. BRISTOWE asked whether it was a safe proceeding to open hydatid tumours by puncturing through the intercostal spaces; in one such case pleurisy developed; at the necropsy his impression was that the puncture had caused death.—Mr. T. HOLMES considered that the point in Dr. Burnet's paper was the question whether an exploratory operation to establish a diagnosis was desirable; any such operation would have been dangerous, and allowed of the establishment of the diagnosis at the risk of the patient's life. Nature had attempted to discharge the hydatids through the bronchial tubes.

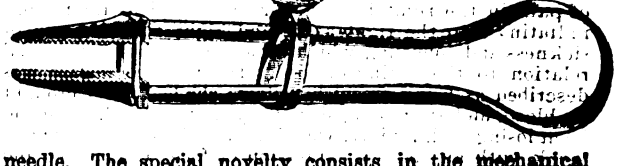
Mr. J. R. LUNN showed a case of Ununited Fracture of the Patella in a man aged forty-four, in which there were four inches and a half separation of fragments, for which excision of the knee-joint was performed, with excellent result. The patient (single) was admitted into St. Marylebone Infirmary in January, 1885. The family history was good. There was no history of syphilis or gout. He scalded his face and shoulders five years ago. He had fractured his left patella sixteen years ago, and union was obtained; he again fractured the same patella six months afterwards, but it never united. He stated "his life has been simply miserable ever since on account of the gnawing pains in the left knee; and everyone used to think he was drunk, as his left knee used to give way under him, though he had worn a splint." On April 14th, 1885, Mr. Lunn excised the left knee-joint, and wired the femur and tibia together with silver wire. The operation was performed antiseptically. Six weeks after the operation the patient's limb was encased in plaster-of-Paris, and he was allowed to get about on crutches. The reason why Mr. Lunn showed this case before the Society was that excision of the knee-joint was so seldom performed after the age of forty-two. In the Med.-Chir. Trans., vol. liii., Dr. Humphreys stated that he excised the knee-joints of forty-five patients, one being as old as forty-seven. In the same volume Mr. Grant gave an account of twenty cases, the oldest being fifty years old. Mr. Lunn's case made an uninterrupted recovery, and with no rise of temperature. The question in his own mind was whether the operation was justifiable.—Mr. T. HOLMES acquiesced in the treatment that had been adopted. Wiring the patella was, in his opinion, a rash proceeding in cases of simple fracture. As to the age at which the knee-joint might be excised, he believed it might be performed at a period of life considerably beyond forty years of age.—Mr. A. PEARCE GOULD considered that Mr. Lunn's case was a successful one. But wiring the patella left the patient with a movable joint. He had performed one such operation on a woman, and there was now a joint having good movement and a strong serviceable limb.

The following living specimens were shown:—Mr. J. R. Lunn: (1) Ulcerating Tumour of Lower Lip, in a man aged twenty-two, of sixteen months' duration; diagnosis uncertain, but father died of sarcoma (? epithelioma) of neck. (2) Frost-bite of both Ears in man. Mr. C. Ballance: Rodent Ulcer of External Ear. Dr. Savill: Ichthyosis Sebacea in a girl.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Dr. Koch's Gelatine Peptone Water Test.



A MEETING of this Society was held on April 16th, the President, Dr. Corfield, in the chair.

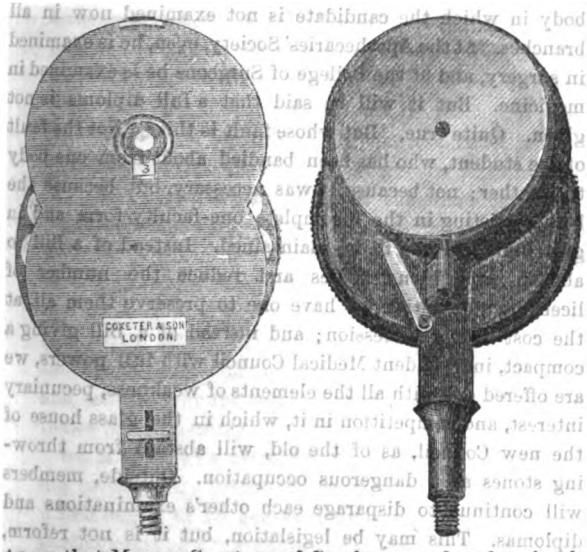
Professor G. BISCHOF read a paper on Dr. Koch's Gelatine Peptone Water Test, of which the following is an abstract. The author stated that he had made hundreds of tests, besides a very large number of experiments with the object of testing the method itself. He asked why should the presence of colonies be regarded as affording evidence as to the purity of water. A satisfactory answer to this could only be given in two ways. Either the colonies might behave in the same way as chemical poisons, being harmless in certain numbers and injurious or poisonous in others; or they must be held to be evidence of some other conditions which affected health. He was convinced that the former was not so, at least not within a very wide limit, say within a million colonies per cubic centimetre, which was a much larger number than any likely to occur in potable water. In proof of this he had taken a sample of New River water, which would still have been called "very good" in quality by Dr. Koch had it contained even twice the number of colonies it did contain. This he kept for six days in a sterilised flask protected against aerial infection, and then found that instead of one liquefying colony he had 540, and instead of a total of fifty-three he had 770,000 colonies per cubic centimetre. Although the sample on the sixth day compared unfavourably as regards numbers of colonies, both with New River water from the company's main to which 1 per cent. of sewage had been added, and Thames water at London-bridge, in such a number of colonies were hurtful we should have known this long since from experience, as water was frequently kept longer on board ship and under much more unfavourable conditions. The only other way of connecting the colonies with purity or quality was if they indicated something else which was injurious to health. This, in his opinion, could only be pollution. He therefore asked, Did the conditions upon which the development of colonies depends warrant any such conclusion? Temperature was perhaps the most important of those conditions, because near the freezing-point development was entirely stopped, whilst it was aided in a most marvellous way as gradually 30° to 40° C. were reached. Of scarcely less importance was the time allowed for development, or, as it would be called in the case of water, storage; next came food, and lastly aeration and light. It was evident that temperature, storage, and light had no necessary connexion with pollution. As regards aeration, it was well known that when there was a deficiency of oxygen the development of microphytes was checked. Therefore, as the deficiency of oxygen generally coincided with impurity of water, the latter would actually check, as far as aeration went, the development of microphytes. Food, the only remaining condition, was always the result of pollution; but even in distilled water, which certainly was not polluted in the common sense of the word, and where there was but a scanty trace of food, very large numbers of microphytes were sometimes developed. Referring once more to the sample of New River water kept for six days, he would ask, if in such water, containing so few organisms, and which was generally so pure, such enormous numbers of microphytes could be developed by storage pure and simple, was it justifiable to say that the number of microphytes depended upon pollution? Thus, there seemed to him an insurmountable difficulty in judging of the sanitary condition of water by the number of colonies, which might or might not be a proper standard in any given case. Nevertheless, he was convinced of the value of the method for a great many laboratory experiments, but in testing water it should be applied with discrimination, and no attempt should be made to compare totally different waters by those numbers. In concluding, the author stated it had been laid down that the presence of many different kinds of microphytes was, *cæteris paribus*, an indication of danger, but he had not seen a single report in which this suggestion had been acted on, and he therefore believed that sufficient advance had not yet been made to allow of drawing definite conclusions from this criterion. The search by the test for specific microphytes, such as were the cause of zymotic disease, did not, for two reasons, rest on a much more satisfactory basis: first, our knowledge of these microphytes was as yet very limited; and, secondly, several of those organised poisons known to us could not at all be cultivated in gelatine peptone, at least not under the ordinary conditions of the test.—In the discussion which followed, the President, Mr. Wynter Blyth, Dr. Klein, and Mr. Cassal took part.

New Inventions.

NEW PRESSURE AND TORSION FORCEPS.

THIS instrument is equally serviceable for four distinct surgical purposes. 1. It can be used as a temporary clamp to arrest hæmorrhage. 2. It forms a very efficient torsion instrument. 3. It serves for the application of a ligature to a divided vessel. 4. It can be used also as a needle-holder, and it is adapted for the introduction of every kind of

needle. The special novelty consists in the mechanical contrivance by which the opening and fixing movements are performed. The points are controlled by the rotation of an oval-shaped collar. In the long axis of this collar the blades are separated by their own recoil, but as soon as they are both turned into its narrow segment they are securely fixed and the points are placed in close contact with each other. One of the blades is loosely fixed by a ring to the



Digitized by Google

end of the collar, which thus forms the centre of rotation and imparts to the collar a sliding motion, so that the blades can be closed at any point as far down as the spring. This sliding movement of the collar greatly facilitates the manipulation of the forceps, and also gives a gradation of pressure and grip at the points. For needle-holding it will be found convenient to work the thumb lever near the shoulder; but for fixing a mass of bleeding tissue the forceps can be readily closed just above the handle. When employed as a clamp for spirting vessels during an operation, the sliding collar can be rotated with great ease and rapidity, and this device will certainly be preferred by many operators to the ordinary sliding and spring catches, and also to the serrated teeth fixed on the ring-handled forceps of Tait and Péan. The instrument is very neatly made by Messrs. Maw, Son, and Thompson.

J. WARD COUSINS, M.D. Lond., F.R.C.S.,
Senior Surgeon to the Royal Portsmouth Hospital, and to the South Hants Eye and Ear Infirmary.

A STUDENTS' OPHTHALMOSCOPE.

THE importance of the ophthalmoscope in medical as well as in ophthalmic practice renders it very essential that every student should acquire dexterity in the use of the instrument as soon as possible after he commences his hospital work, otherwise the most valuable opportunities of gaining experience are lost to him for ever. As a matter of fact, scarcely any student learns to use the ophthalmoscope efficiently until he has one of his own. Unfortunately the cost of really useful instruments prevents many students obtaining one as soon as is desirable. We are glad, therefore,

to see that Messrs. Coxeter and Son have produced a simple but excellent ophthalmoscope at a price (15s.) which brings it within the reach of every student. It is a refraction ophthalmoscope, with eight lenses, each ¼ inch in diameter, fixed in a revolving disc. The mirror can be placed in either of two sockets, in one of which it can be tilted for the direct examination. A bi-convex lens and neat case are included in the price. On trial of the instrument, we have found it perfectly satisfactory and equal to much more costly ophthalmoscopes. It is, indeed, easier to use than many instruments on account of the large size of the back lenses.

"OSTERODE" HEALTH CLOTHING.

MESSRS. SLAZENGER AND SONS, of 56, Cannon-street, have sent us samples of their "Osterode" Health Clothing, and also of the unmanufactured article, which is wool grown in a district in the Hartz Mountains. From an examination of the above, and also from personal experience of the comfort derived from wearing the clothing, we can say that Messrs. Slazenger have introduced a highly commendable commercial article. The wool is peculiarly soft, and the woven goods are free from roughness and irritating properties; in fact, the clothing closely resembles silk in its softness, durability, and pleasant wear. We cannot, from our own knowledge, testify to the special curative and prophylactic properties of the various forms of vestment claimed for them by the manufacturers in the treatment of rheumatism, but at the same time we are justified in saying that Messrs. Slazenger's goods are well calculated to enable the wearer to avoid chills and colds, and we can conscientiously recommend its adoption both for winter and summer wear. The prices of the various articles are comparatively low.

THE FELLOWSHIP OF THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—As a provincial surgeon, I was pleased to learn through your columns that the Council contemplate admitting Members of fifteen years' standing to the Fellowship on passing the second examination—that in surgery, surgical pathology, and surgical anatomy. This is, I think, as it should be. It will permit many Members, whom accident and the nature of special surroundings compel to practise largely as operating surgeons, to obtain the Fellowship, and be an inducement to them to work up to the standard required by this diploma.

I should like to know when the Council intend to make the necessary alterations in their bye-laws, so that the proposal can take effect. I hope they will not wait until the new Charter has been obtained, for under the most favourable conditions a long time must elapse before that can be accomplished.

I am, Sir, yours &c.,
May 3rd, 1886. M.R.C.S.

STUDENTS AND THE MEDICAL BILL.

To the Editor of THE LANCET.

SIR,—The imminent probability that the Medical Bill now before the House of Commons, and which has already been read a second time, will ere long become law, renders it particularly desirable that an early attempt should be made to secure such amendments of its clauses as are necessary in the interest of all classes of the profession. A uniform standard of minimum qualification, and the adoption of a descriptive title by which every registered medical practitioner shall be designated, are the points which are especially important from the student's point of view. They were urged by a deputation of metropolitan students of medicine before Mr. Mundella when the ill-fated predecessor of the present Bill was in process of abortion, and the success then achieved encourages the hope that a similar deputation to Sir Lyon Playfair at this crisis may result equally satisfactorily. May I ask your powerful aid in this matter, and suggest that a meeting of students be held at each hospital in London, when one or two delegates should be appointed to represent the majority on the proposed deputation, and it might be desirable to hold as well a general meeting of students and others at some centrally situated spot. If done at all, this thing must be done quickly, and I shall be glad to receive communications on the subject from gentlemen willing to organise the necessary gatherings at the various hospitals.

I am, Sir, yours truly,
CHAS. H. WADE, B.A. Oxon., M.R.C.S., &c.
Beauclerc House, Upper Norwood, May 5th.

*** The interest of students in an amendment of our medical examining system is obvious, but it is little considered. Corporations lay heavy burdens upon them of money and of examination, and pay little heed to the simplification and the absolute fairness of the ordeals by which they are to be tried. They have a somewhat despairing feeling of helplessness, but they have a right to ask a minister who claims to be protecting the public from unqualified practitioners to protect them from unreasonable exactions on the part of the examining bodies, and, when they have gained professional titles, to have them duly respected.—ED. L.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, MAY 8, 1886.

THE subjection of the Medical Profession to the Privy Council proceeds with little protest but our own. As we have already said, it seems not impossible, if the present Parliament does not come to a premature dissolution, that Sir LYON PLAYFAIR may carry his Medical Bill. It was read a second time on Monday night, and the Committee fixed for Monday, the 17th inst. In medical politics Sir LYON PLAYFAIR has always been an *opportunist*. When it might have been in his easy power, fifteen years ago, to obtain direct representation for the profession, he did not move a finger to get it inserted in a Bill which would have given far better Conjoint Boards than this, and which would actually have removed the scandal of so many examining bodies, so likely to survive under this Bill. He has left others to fight the battle of direct representation, and now, when it is fought and won, and the principle everywhere conceded, he, with all the powers of a Vice-President of the Council, brings in a Bill to add four direct representatives: TWO to represent, as Dr. FOSTER said, 16,978 practitioners in England, *one* to represent 2372 practitioners in Scotland, and ONE to represent 2500 practitioners in Ireland. The other elements of the Council are to be unchanged. What justice is there in such a proposal as this? What fairness to the practitioners of England in their numerical proportion of seven to one in the other divisions of the kingdom? Still more, what is the good of such an arrangement? What could four direct representatives do against twenty-four representatives of universities and corporations which not only have pecuniary interests, but which interests the profession knows have been constantly uppermost in the consideration of their representatives in the Medical Council, and which the present Bill does not dare to interfere with, whatever justice to the profession or to medical students with the ordeal of ever-accumulating and more exacting examinations may demand? But we are told by Sir LYON PLAYFAIR that this Bill secures certain great improvements — especially *two*. It provides that every person entering the profession shall be examined in each branch of practice — *Medicine*, *Surgery*, and *Midwifery*; and, secondly, that if the examining bodies fall short of a good standard, as even certain Royal Colleges are said to have done, under the demoralising conditions of rivalry and competition, which will be largely perpetuated under this Bill, the Medical Council may, *with the concurrence of the Privy Council*, disqualify that unworthy body. May! Sir LYON PLAYFAIR knows well that such a power has resided in the Medical Council ever since it was a Council. He knows well, too, that the Council has never either dared or cared to exercise it, though some of the different bodies of which the Council consist have and still continue to hold the most contemptuous views of each other's examinations. This mutual disrespect of bodies that still stand well in their own eyes is a most painful fact to all acquainted with the state of matters, and is doing much harm. A remedy should be found for it in a well-constructed Medical Council, with perfect independence, and with duties of supervision not only over diploma-granting bodies, but over universities which grant degrees, so that the character of medical graduation be duly maintained. Instead of that, in this Bill universities are only regarded as corporations, and their standards will not be criticised further than to see they come up to the mark of securing bare competence. Let the House of Commons, then, not be misled by Sir LYON PLAYFAIR'S rosy accounts of the absence of opposition to his measure on the part of the examining bodies. Their silence is his condemnation. They do not oppose the Bill because it does not reform them. It practically leaves them alone, and leaves them in full possession of their representation in the Medical Council; and, for aught we know, will leave them to compete with each other and to despise each other, as at present, to the great injury of the profession and of that good and respectful feeling which ought to obtain between analogous bodies in different divisions of the kingdom.

But we shall be told that the Bill secures examination in all branches of the profession—medicine, surgery, and midwifery: as if this were a great boon to be thankful for. This is secured already. There is scarcely one examining body in which the candidate is not examined now in all branches. At the Apothecaries' Society, even, he is examined in surgery, and at the College of Surgeons he is examined in medicine. But it will be said that a full diploma is not given. Quite true, But whose fault is this? Not the fault of the student, who has been bandied about from one body to another; not because it was necessary, but because the bodies existing in the incomplete one-faculty form and in great numbers had to be maintained. Instead of a Bill to abolish superfluous bodies and reduce the number of licensing authorities, we have one to preserve them all, at the cost of the profession; and instead of a Bill giving a compact, independent Medical Council with full powers, we are offered one with all the elements of weakness, pecuniary interest, and competition in it, which in the glass house of the new Council, as of the old, will abstain from throwing stones as a dangerous occupation. Outside, members will continue to disparage each other's examinations and diplomas. This may be legislation, but it is not reform, and it excites in us neither admiration nor gratitude. To crown all, the new Medical Council is scarcely to take a step without the consent of the Privy Council, which is mentioned between forty and fifty times in this Bill. We must still hope that some adequate and effective criticism will be applied to it by some independent and intelligent member of the profession in the House.

DR. MAUDSLEY contributes to the current number of the *Fortnightly Review* an interesting paper on "Heredity in Health and Disease," wherein he sets out in an orderly and intelligible shape the laws which govern the inheritance and transmission of disease, so far as these are ascertained. It is needless to say that this is admirably done, and that the reader will find light and leading in the perusal. Meanwhile Dr. MAUDSLEY would seem to write with the feeling that what he has to say is new; whereas,

Digitized by Google

though not perhaps as widely known as they ought to be, the principles of heredity, so far as they are expounded in this article, have certainly been before the profession and the public for some years at least. Even in respect to the utilisation of disease-tendencies and disease-immunities in the rectification of faults and liabilities of the organism Dr. MAUDSLEY has been anticipated. This is how he states the case: "Here, then, we perceive the opening of a most interesting and fruitful line of medical inquiry, not yet ever seriously attempted, namely, the production and the elimination of constitutional disease-tendencies and disease-immunities in the offspring by the combinations of different parental disease-tendencies and immunities. And not of disease-tendencies only of the same kind as the parent has. If a child have a disease unlike that which either parent had, it may nevertheless owe it to them; for there is abundant reason to believe that variations may occur in morbid heredity, just as they do physiologically." Dr. MAUDSLEY must be well aware that "the eradication of disease" by developmental processes has been repeatedly discussed and enforced by medical writers. Thus it has been suggested to meet the tendency to tubercular disease by the calling out of energies incompatible with the consumptive habit, and to seek the repression of undesirable characteristics whether of body or "mind"—to use the conventional phrase—by the development of other characteristics, trained, so to say, across them. And it has been again and again contended that the individual must be studied, if any good is to be done, in the light of the ancestral inheritance. And that the well-known rules which govern the improvement of stock by "cross-breeding" and the introduction of new "strains" should be, as far as practicable, applied to the improvement of the race and breed of man. There is nothing new in the suggestion. This much it is necessary to say on the point of originality in respect of the views set forth in this paper before. They have been for many years past before the profession and the public, and they are illustrated and enforced by the experience of every intelligent practitioner in the country.

Dr. MAUDSLEY'S essay will do excellent service by bringing prominently before the reading community principles which ought to be generally understood. As it was contended years ago, "Nothing is done to cut off the entail of consumption, gout, hereditary brain and nerve disease, or a score of other transmitted constitutional affections. Excepting vaccination as preventive of small-pox, we have no systematic plan of treatment for the elimination of those congenital tendencies and potentialities from which spring some of the most formidable diseases. The omission is, however, one of grievous consequence to youth. When the young man or the young woman comes to face the toil and risks of life, the strength of body and mind is found to be impaired, and existence itself handicapped by the burden of entailed constitutional weakness and disease. To cut off the entail completely, it would be necessary that at least two or more lives should be placed under discipline. Parents and children must both avoid modes of life and practices calculated to increase the mischief, and further prejudice the estate. The sins of the fathers are visited upon their children, even to the third and fourth generation. Many a youth falls a victim to consumption or brain disease because his father or grandfather elected to gratify his coarse animal appetites and lead a vicious and dissipated life. When the inheritor of organic peculiarities, thus acquired and transmitted, himself adds recklessness to danger, the result can scarcely fail to be signal disaster. What are called 'morbid germs' would probably be more accurately described as abnormal developments or states of the system, which render the phenomena of disease likely to occur. When these states begin in disorder of function, the irregularity speedily reacts on the organism, and, in obedience to the law of natural development, produces a change of structure corresponding to the disease. In the course of two or three generations a morbid peculiarity of the physical system—whatever it may be,—which at first was an effect, begins to operate as a cause, and thus the disease by which the change was wrought in the system is rendered *hereditary*, being reproduced by the special morbid type of development to which it gave rise. Thus is how it comes to pass that certain families are distinguished by what is known as a 'consumptive physique," while others are 'asthmatical,' 'gouty,' and the like. It is not sufficient, nor is it wise, to wait until the children of gouty, rheumatic, asthmatic, or bronchitic parents, and those labouring under other known diseases, exhibit the formulated symptoms of a constitutional taint. Before this point is reached the young organism will have suffered serious injury by the occult workings of the malady. Preventive medicine should recognise the evil and grapple with it while it is still burrowing in the dark. Specific diseases known to exist in a family should be treated in every member without waiting for indications. The maxim 'Let sleeping dogs lie' is often of value in dealing with adults, but it is inapplicable in the case of children; because in the child-state, and while the organism is still in process of development, the constructive forces can be enlisted in the work of cure."

This is the practical moral, as regards the individual, of the story Dr. MAUDSLEY has to tell, though it was pointed and printed years ago. The moral as regards the race is that parents should be so selected and combined that their offspring may be healthy, the resultant of the two paternal forces, which will of course differ from both in *plus* and *minor* characteristics and qualities, being something foreseen by science and intentionally developed. Dr. MAUDSLEY recognises and gives expression to this idea, and yet he has not, apparently, so much faith in the application of the principle he expounds as the doctrine he preaches certainly justifies and would seem calculated to inspire. He says: "It is not possible to predict what will be the exact mental qualities and bodily features of the child of two persons whose characters we know very well, nor so much as to tell what its sex will be." It would have been better to say—The present state of knowledge does not enable us to make these vaticinations with certainty; because it is obviously only the defect in our comprehension of facts which renders the foresight required so difficult as to be unattainable. There can be no actual obstacle in the way of foretelling both sex and character, physical and mental. Dr. MAUDSLEY vies with Professor HUXLEY in his admiration of DESCARTES, and, like the Professor, hails him as the originator and father of modern philosophy. No one will dispute the position thus taken

Digitized by Google

up, though there may be some who would qualify the praise lavished on DESCARTES by both HUXLEY and MAUDSLEY. We commend the paper on "Heredity in Health and Disease" to the attention of our readers for its perspicuity and practical value as a contribution to the recent literature of a subject which is inadequately understood by the outside public. We cannot, however, concede to Dr. MAUDSLEY a claim to originality.

THE short-sightedness of the enemies of vaccination is shown in nothing more than in their opposition to compulsory public vaccination. The very fact that the State compels vaccination ensures in the long-run the safety of vaccination. The State feels its responsibility for having the work done well, and very effectually impresses this wholesome feeling on all its agents in the performance of the operation. Those who do well are rewarded, and those who do not do well suffer loss. We record almost weekly the award of grants to public vaccinators for their work—that is to say, a certain extra payment, over and above the ordinary vaccination fee, for each case realising certain tests of good vaccination, such as the production of four separate good-sized vesicles which shall leave marked foveation or pitting, thus defined: a *first grade*, with scars having collectively at least half a square inch total area; or a *second grade* (admitted only in cases of a first award), with scars less than the above, but having collectively at least one-third of a square inch total area. The report of individual awards gives little idea of the extent of good public vaccination. Rather must this be gathered from the Annual Report of the Local Government Board. The fourteenth Annual Report is before us—that for 1884–5; and from this we learn that about two-thirds of the public vaccinators vaccinate so as to get awards. Thus the medical staff of the Board visited 245 unions containing 1096 vaccination districts. To the vaccinators in 729 of these districts special awards were made by the Board on the reports of inspectors as to the quality of vaccinations performed. Unfortunately there is no such public record or report of the excellence of the vaccination performed by private practitioners, much of which would bear a favourable comparison with that done by public vaccinators. There is another illustration in this Report of the way in which a system of public vaccination promotes care and purity of vaccination. A great supply of vaccine lymph is maintained by it, enabling the Local Government Board to give lymph to practitioners who apply for it to start a local series of vaccinations. Practitioners can be now supplied either with human lymph or with calf lymph. But the point we are concerned with just now is this, that all lymph so supplied by its officers to the Local Government Board is carefully examined, and that such is the pains taken to secure satisfactory lymph, and such the success, that of 11,447 applications dealt with during the year, no suggestion of resulting syphilitic disease was heard of in any one case, and the Board was able to speak with thorough confidence of the purity and efficiency of the lymph.

We rejoice to see, in the main proof of the continued public confidence in this greatest of all devices for averting death and disease. In St. Pancras a remarkable vaccination census was taken, which showed that of 25,917 persons over one and under ten years of age, no less than 25,692 or more than 99 per cent., had been vaccinated; while of 112,425 persons over ten years of age, 71,213, or 63 per cent., had been vaccinated once; 39,835, or 35½ per cent., more than once; and only 1377, or less than 1½ per cent., were unvaccinated. Those who have discovered the beauty of small-pox and the horror of vaccination may well be staggered at the persistence of the "great delusion," but men of common sense will see in facts like those of St. Pancras and other populous unions, such as those containing Birmingham, Leeds, Blackburn, &c., where the unvaccinated only reach 1·4 per cent., an ample justification of the Vaccination Acts, and satisfactory evidence that on the whole they are appreciated by the people.

THE growth of Provident Societies, more especially amongst the industrial classes, is regarded, and very justly so, by men of all shades of opinions as one of the most hopeful features of modern social progress. If the system of assurance against sickness and death could be made universal, workhouses would disappear, the pressure on hospitals be vastly relieved, and private charity might to a great extent be dispensed with. Parliament has recognised, though somewhat tardily, the national importance of the provident movement, and for its stability special statutes have been enacted. It therefore becomes a matter of general concern to be informed by an officially appointed actuary of high repute that his valuation of the assets and liabilities of a provident institution has resulted in establishing a deficiency of £115,994. Such is the pith of a published report, dated 21st January last, by Mr. HOWARD S. SMITH, actuary, at Birmingham, on the Cannon-street Male Adult Provident Institution in that town. The deficit is happily not an actual one in cash, as the audited balance-sheet for 1885 proves a total in hand and in first-class securities of £83,185 1*s.* 2½*d.* No less satisfactory is it to note that no question of malversation is raised. Everything is in order, and the management is stated to have been unimpeachable; but the nominally *provident* institution appears to be travelling on *improvident* lines in paying out more than it is justified in doing according to the scale of contributions. Generosity seems to have once more outstripped prudence.

The objects of the Society are twofold: the relief of members in case of sickness or any other infirmity such as would render them incapable of working for their support, and to render assistance on the death of a member or his wife. Last year the Society had 9598 members. The payments for sick relief reached £12,613 10*s.* 5*d.*, for medical attendance and medicines £1375 11*s.* 9*d.*, and for members' and wives' funerals no less than £3213. The medical staff includes twenty-six legally qualified practitioners, and, additionally, seven consultants to whom the Society pays regular fees, when on duly certified urgency a consultation is deemed necessary. When it is added that the annual income of the institution is £16,600, and that within the last ten years the members have received, exclusive of medical attendance, £123,444 8*s.* 10*d.*, nothing more need be said to prove that the adverse actuarial reports are matters of weighty general interest. Mr. HOWARD S. SMITH, whom we have already quoted, regrets that his report must be unfavourable, and his eminent predecessors said substan-

Digitized by Google

tially the same. In 1871 Mr. F. G. P. NEISON (an investigator and writer of great reputation on friendly societies' statistics) reported that for the provident institution under consideration to be in a sound financial condition, its accumulated funds should be increased by at least £21,244 1*s.* 11*d.* This deficiency had risen to no less than £96,679 at the end of 1879, when the state of affairs was investigated (pursuant to 38 and 39 Vic., cap. 60, sec. 14) by Mr. A. J. FINLAISON, the actuary to the National Debt Commissioners, who very plainly set forth "the gravity of the position of affairs." All the actuaries have agreed that the chief cause which is weighing down the financial balance with such increasing weight is the liability at death without adequate provision. As a sick society we conceive this provident institution might be practically solvent, according to the members' present payments; but as a sick and life insurance society the present financial disequilibrium, which is remediable, may prove disastrous insolvency. But a very small increase in the payment of each member, not more than twopence or threepence weekly, might stem the downward current, and in a few years restore stable prosperity The whole question is to be considered at a special general meeting of the members of the Society to be held in the Birmingham Town Hall on the 27th inst., at 8 P.M. Conceding to the fullest that in such a mutual society every member has a right to vote on the ultimate disposal of the common property, thousands of men in public meeting assembled are not the most competent court of appeal from a decision pronounced independently by such actuaries as Mr. HOWARD SMITH, Mr. NEISON, and Mr. FINLAISON. It may be difficult to convince many of the 9600 members that a society with £83,000 may be insolvent; but a little reflection will satisfy anyone that a provident institution with £1000 may be rich, and one with a thousand times that amount hopelessly bankrupt: it is a question of the proportion of liabilities to assets. The members of the Cannon-street institution are all growing older—drawing nearer to times of sickness and to the certainty of death; their ranks are being steadily increased, and yet their capital is shrinking, whereas it should be rapidly accumulating to meet inevitable future demands. One fact not to be overlooked is that the experience of sickness of the members has exceeded the computation, and the medical officers may assist materially in checking this source of loss by limiting sickness allowance to proved inability to work. Malingerers are difficult to detect; and in times of bad trade like the present many men lack the best stimulus to shake off slight ailments. But, with every economy, the deficit must grow, unless the substantially unanimous advice of the actuaries be acted on.

Suggestions have been thrown out to reduce the expenses of management, and to alter the system of administering medical relief by appointing two or three surgeons exclusively to attend to the members. Such proposals in the pending crisis recall ABRAHAM LINCOLN'S famous warning against the imprudence of "swopping horses while crossing a stream." No one has impugned the ability or the integrity of the Society's management, and every member living within a radius of three miles has a choice of any one of the twenty-six members of the regular medical staff. It is not questioned that these gentlemen have long enjoyed the public confidence, and that they discharge their duties with ability and conscientiousness. It would be a mistake to divert attention into a side issue, when it should be riveted on the great fact which the actuaries have established, and on the remedies which in principle they have advised. If the present benefits are to be maintained, the members' contributions must be increased; if these are to stand as at present, payments at death must be abolished, and sick pay may have to be reduced. The Society has been in existence forty-five years, it has done an incalculable amount of good, and may have before it a long life of increased and honourable usefulness, if only the great principle of thrift be practised—to make present sacrifice for future good.

AMONG the agenda for the consideration of the members of Convocation at their annual meeting on the 11th inst. the proposals for reforming the constitution of the University of London occupy a prominent place. The Special Committee nominated by Mr. MAGNUS in December last has apparently matured a scheme, which Convocation will be formally asked to receive. The scheme, however, has not yet been printed and circulated, so that its consideration will probably be postponed until the end of next month, when a special meeting must be summoned. The points of resemblance and difference between it and Lord Justice FRY'S scheme will be keenly scrutinised, and we shall be much surprised if there be found sufficient improvements therein to justify the obstruction and the delay in pushing the reforms forward. Meanwhile Mr. TYLER and Mr. SPRATLING are anxious that Convocation should settle the matter offhand, and hence they will move resolutions of their own. Mr. TYLER'S proposals are: an increase in the number of senators nominated by Convocation, and the limitation of their tenure of office to a term of years; the formation of a Congregation, composed of the Senate, certain members of Convocation, examiners, and representatives of affiliated institutions, to advise the Senate on the examination regulations; an increase in the powers of Convocation; and the establishment of University lectureships. Mr. SPRATLING'S proposal goes much further in the direction of bringing the Colleges into closer connexion with the University and of giving some direct influence to their representatives, and in this respect approaches much more nearly to Lord Justice FRY'S plan of reform. But all these suggestions must have been before Mr. MAGNUS and his committee, and will doubtless be dealt with in his report, so that Convocation will probably refer these resolutions also to a special meeting. The position of reform is greatly altered by the recent additions to the Senate, for Mr. HENRY MATTHEWS, Q.C., and Dr. PYE-SMITH, were active members of Lord Justice FRY'S Committee, and are bound to urge the speedy consideration of the question. But what is the Executive Committee of the Association for Promoting a Teaching University doing? An exceedingly able letter has been drafted and sent to the various teaching institutions in London of university rank, to the medical schools, to the Senate of the University of London, and to the professional corporations, but, so far as we can gather, no action has resulted therefrom except in the University itself. Sir EDWARD FRY has shown his continued interest in the movement by moving for a Committee of the Senate

Digitized by Google

to consider and report on the letter, and, if necessary, to confer with the Executive Committee. It will be indirectly, by favouring internal reform in the University of London, and by compelling the London Colleges of Physicians and Surgeons to follow in the line of the opinions of those advocating the establishment of a Teaching University, or in being joined thereto, and so increasing the literary and scientific elements in their examinations before they can be granted the power of giving degrees, that this Association will justify its existence, rather than by any direct action of its own.

Annotations.

"Ne quid nimis."

UNCERTIFED CAUSES OF DEATH IN LARGE ENGLISH TOWNS.

THE Registrar-General reports in his Annual Summary for 1885 that the causes of more than 4000 deaths registered during that year in twenty-eight of the largest English towns were not certified, signifying that in this large number of cases no legal certificate of the cause of death under the hand of a registered medical practitioner or of a coroner was produced to the civil registrar at the time of the registration of the death. It further appears that these deaths were in the proportion of 2·3 per cent. of the total deaths registered in those towns during the year. This proportion was slightly below the proportions that prevailed in the preceding three years, when they were 2·5, 2·6, and 2·4 per cent. respectively. It may readily be imagined that in a certain proportion of deaths, more especially of those of infants and old people, there may not be such medical attendance during the last illness of the deceased person as the Registration Act contemplated when it fixed the obligation of furnishing certificates of the cause of death upon medical practitioners. There seems no good reason, however, why this proportion of what may be called necessarily uncertified deaths should vary very widely in different towns, although the proportion may be to some extent dependent upon the social condition of their populations—that is, upon the relative amount of the poorer classes. The varying proportions of uncertified deaths in the twenty-eight large English towns cannot therefore be referred to this cause. It appears that during 1885 the proportion of uncertified deaths was equal to 1·1 per cent. in London, against 1·2 and 1·3 per cent. in the preceding two years. In the twenty-seven provincial towns the percentage of uncertified deaths averaged 3·2, or nearly three times that in London, and ranged from 0·6 in Plymouth, 1·2 in Brighton, and 1·3 in Portsmouth, to 4·8 in Liverpool, 5·6 in Hull, 6·1 in Sheffield, 7·0 in Halifax, and 7·5 in Oldham. With reference to the five last-mentioned towns, it may be noted that they also showed a large excess of uncertified deaths in each of the four years 1882, '83, '84, '85; and that the proportion of uncertified deaths has been remarkably stationary in Liverpool and Hull, while it has shown a constant tendency to increase in Sheffield and Oldham. It may be pointed out that the numbers of uncertified deaths and of inquests are almost invariably in inverse proportion to each other. The proportion of inquests to total deaths in the twenty-eight large English towns during last year averaged 6·4 per cent., scarcely differing from the proportions in recent years; the proportion, however, in each of the five towns above mentioned, with the largest excess of uncertified deaths, was very considerably below the average. The highest proportion of inquest cases in these five towns was 4·8 in Liverpool, whereas Halifax and Oldham, which had the largest proportions of uncertified deaths, showed the absolutely lowest proportions of inquest cases—only 2·9 and 2·7 per cent. respectively. It cannot be doubted that the high proportions of uncertified deaths in these five towns afford a tolerably accurate gauge of the amount of unqualified medical practice prevailing therein; and it is only necessary to refer to the reports of proceedings in police and coroners' courts to prove how much of this unqualified practice simply means imposition on the ignorance and carelessness of the poor. In the present condition of the law respecting uncertified causes of death, the co-operation of the coroners of our large towns appears indispensable to protect the poor from this dangerous form of imposition.

CHOLERA INTELLIGENCE.

So far as Europe is concerned, definite news as to cholera is still confined to Brindisi and the Adriatic coast. But unfortunately the disease is extending, and this under circumstances that must cause the greatest anxiety. Thus, the city of Venice is infected, and its sanitary circumstances are not such as to give hope that at this season of the year the disease will be merely of a sporadic type. On May 5th ten cases and three deaths took place there, and there can be but little doubt that these are not the first attacks. Then, again, the disease has extended inland as far as Vicenza, an important town lying on the line of railway between Venice and Verona, and rather more than midway between the two places. Nine cases were reported there on May 4th, and two more on the 5th. The first rumour of cholera in Venetia, during the present European epidemic, dates as far back as September, 1884, when two deaths occurred there. Off and on, rumours of isolated attacks have been renewed, and since the commencement of the year the disease has been scattered about the coast line as well as inland. Under these circumstances, the sudden announcement of so many cases in the province, together with the extension into a neighbouring province at the commencement of the hot weather, bode ill for North-eastern Italy. Several cases still occur daily at Brindisi, with occasional deaths; but in that port the disease is said to be abating, and to be losing its more distinctive characters. A private letter published in Vienna further states that the disease has been imported into Salonica by Italian sailors, and that there are cases in the hospitals there.

"EXHIBITIONS."

WE hail the opening of another "Exhibition" in London on grounds of public health and happiness. This huge melancholy city has positively no open-air amusement for the public except such as these exhibitions afford. The "gardens" which supplied our fathers and grandfathers with places of resort, where it was possible to spend some portion, at least, of a fine evening out-doors without being wholly deprived of the means of entertainment, have been improved off the face of the earth. It is therefore most satisfactory to find that, by fortuitous circumstances no doubt, the progress of enlightenment and enterprise has provided us with a substitute. It is devoutly to be hoped that those who have shown so much good-will to the public in organising the summer exhibitions of the last few years will not grow weary of their kindly service, and that the public will, by their patronage of the entertainments provided for them, justify, and in some part requite, the effort made to serve them. We have long felt, looking at the matter from a health point of view, that something ought to be done to supply London with the means of out-door amusement available for the summer evenings, and for the classes whose only time of leisure occurs after the

Digitized by Google

business hours of the day are over, as well as for those who can resort to such pleasurable scenes by day. Certainly no more admirable attraction or means of entertainment could well be devised than that afforded by the Exhibition which Her Majesty graciously opened on the 4th inst., and which the public owe mainly, if not solely, to the good taste and loyal enterprise of the Prince of Wales. The community will not be slow to appreciate His Royal Highness's most excellent help in this matter. Edinburgh and Liverpool are similarly favoured with exhibitions, and we doubt not that their appreciation of the value of the boons conferred on them will equal our own. There is a black lining to every silvery cloud, and it is to be regretted that the managers of theatres and some tradesmen are not as much advantaged by exhibitions as the general public. Perhaps when once the habit of seeking amusement away from home in the summer evenings is gradually formed by the pleasant education we are undergoing, those whose business it is to provide the public generally with entertainment may find their coffers more quickly recouped. Trade must beget trade, so that in the long run the shopkeeper cannot possibly lose.

BERI-BERI.

AN industrious investigation of some of the circulatory conditions that obtain in the Japanese "kakké" or beri-beri has been undertaken by Dr. Wallace Taylor, with the production of some valuable results. In none of the cases was there organic disease of the heart or arteries, and no functional derangement other than that attributed to the influence of the "kakké." Sphygmographic tracings revealed a very sudden and high upstroke, with precipitous descent from the apex of the percussion wave and marked dicrotism. The first deviation of the circulatory system in kakké from the normal is one of cardiac excitement. There is also diminished tension, due to loss of arterial tone. The chief causes of danger in the acute disease are found in the impaired condition of the heart and enfeebled circulation. The extent, however, to which the heart and vaso-motor system are affected in the disease is liable to relatively large changes. Dr. Taylor considers that all the conditions of the heart and arteries can be explained by the action of the *materies morbi* of kakké upon certain portions of the cerebro-spinal nerves and sympathetic system. Age exercises considerable influence over the occurrence of the disease, which is most common between sixteen and twenty-eight years of age. One attack of kakké appears to render the patient more liable to subsequent affection. Women are much less likely to be affected than men. Though the female sex in general enjoy a marked immunity, yet in the puerperal state they are very liable to take the disease. It is but seldom that traces of albumen are found in the urine. Partial paralysis of the muscular walls of the bladder is occasionally to be met with. No mention is made of the multiple neuritis, of which so much has lately been written in England.

A CHEMICAL ANALYSIS DESIRABLE.

A LITTLE more than a week since an inquest was held at Sutherland respecting the death of a boy aged six years, who retired to rest one evening complaining of toothache. In the night he vomited, and the next morning he died apparently exhausted. The post-mortem examination revealed some red patches in the stomach, but no other diseased condition that would point to the primary cause of death. We regret that an analysis was not ordered by the coroner; but the jury expressed themselves satisfied "that deceased had died from the effects of excessive vomiting, but what caused this there was not sufficient evidence to show." Exactly; that is just why we contend a further examination should have been made by a skilled analyst.

LIVERPOOL MORTALITY IN RELATION TO WORKS OF SEWERAGE.

IT is now over fifteen years since Dr. Burdon Sanderson and the late Dr. Parkes, at the instance of the Corporation of Liverpool, made a report on several of the more important matters affecting the health of the city. One of the recommendations they submitted aimed at the removal of injurious conditions of sewerage, including especially the provision of adequate sewer ventilation. On receipt of this report the Corporation undertook an exhaustive inquiry into the state of the city sewers, and the late engineer commenced by freeing them from deposit and by providing ventilating manholes or shafts at a distance of not less than 100 yards apart. Mr. Clement Dunscombe, the present city engineer, has followed out the work of improvement, and he now submits a report which shows how large an amount of valuable work has followed on the joint report of fifteen years ago. Gradually the system of sewer ventilation has been perfected, and whereas prior to 1871 there were only "Archimidean" screw ventilators connected with branch sewers in courts, &c., ventilating openings of not less than sixty-three inches in superficial area have now been fixed at a distance of about eighty yards apart along the lines of sewers; this work having been completed in 1882. Indeed, in 1882 as many as 177 miles of sewers had been ventilated, and between 1876 and 1885 as many as 72 miles of new sewers had replaced such as were, by reason of their favouring deposit or otherwise, faulty in point of construction. The passage of road detritus into the sewers by the road gullies was also found to have largely worn the inverts of the sewers, and many of these have now been re-inverted with Portland cement concrete, others being altogether replaced by the best blue bricks, moulded to the respective radii. So, also, the gullies themselves have been so reconstructed that detritus can easily be removed from them before it has a chance of passing into the sewers. Attention has, however, been by no means limited to the public sewers, for bye-laws, which have been confirmed by the Local Government Board, are now in force in connexion with the construction of house drains, and, as Mr. Dunscombe very truly points out, it is found that the highest standard of house drainage is extremely simple and can be carried out at a moderate cost. Bye-laws regulating this subject are, as a rule, of but imperfect service, unless steps are taken to secure their proper administration; and here Liverpool has acted wisely by appointing an inspector for each of the districts into which the city is divided for this purpose, and it is the duty of these inspectors to see that the work is in each case executed in accordance with the regulations and the plans which have been approved in the engineer's department. For all the valuable and necessarily costly work, some result should properly be forthcoming. The work is only just completed, and hence its effects may be expected to show themselves in a more striking manner in the future than at present; but still, it is interesting to note the death-rate of the city during the several periods antecedently and subsequently to the execution of these works. For the ten years 1861–70 the death-rate per 1000 living in Liverpool was no less than 32·5. Between 1871 and 1880, the mean rate had fallen to 28·4, and since then a steady uninterrupted fall has been maintained, until in 1885 we find it standing at 23·7. Mr. Dunscombe would, we feel sure, be the first to admit that many influences, other than improvements in sewerage, have been at work in producing this great saving of life; but whilst this must necessarily be so, we would unhesitatingly assert that, had the state of the sewers remained to this day the same as it was at the date of the Sanderson and Parkes report, much of the substantial reduction in the death-rate which has

Digitized by Google

taken place would never have been secured. The experience of Liverpool in this respect should act as an incentive to sanitary authorities in all parts of the kingdom.

THE PRODUCTION OF MALARIA.

THE connexion between forced vegetable decomposition, insufficient drainage, and the rapid rise and fall of streams on the one hand and malaria on the other, has long been recognised, as also has the influence of season in the production of the disease. The matter has received considerable attention in various parts of the United States, where malarial disease constitutes a constant source of danger to health in special localities; and in the ninth report of the Board of Health of New Jersey certain local causes of the prevailing evil are discussed. Thus, the influence of mill-dams is alluded to. At Bound Brook at one time the entire population was prostrated by the various forms of malarial fever. Every year witnessed many cases of the disease, sudden "wilting" of swamp vegetation and sudden changes in the atmosphere and rainfall materially influencing it. A local dam was removed and the swamp was drained, the result being that malarial disease, with its chills and fever, has almost entirely disappeared. In other places, until recently remarkable for healthiness of site, the diversion of streams for artificial ice-ponds and other purposes has added to the pollution of vegetable decay, dams have been constructed for similar purposes, and, as a result, obscure forms of malaria are becoming fairly settled in the localities. In much the same way the influence of decomposing sawdust is regarded as causing malaria. The material, in its putrefactive processes, very much resembles other vegetable matters, and the experience of the Ontario Board of Health is quoted as showing how deposits of sawdust along the shores of streams, and especially on those of bays and ponds, in undergoing decomposition, have led to injurious results, including the production of malarial diseases. Dr. Hargis, who is well known in connexion with his careful observations on yellow fever and other subjects, has stated that on the west coast of Florida, where malaria is seldom found, it has always, when it has appeared, had a saw-mill as its centre. The conclusion come to is that the decay of vegetable fibre is connected etiologically with malaria, and that inspection of streams is necessary to its prevention. In much the same way, it is also regarded that injury to health is likely to ensue if ice-ponds are constructed in marshy spots, the ice itself tending to be unwholesome if cut from stagnant, shallow pools. Indeed, legislation has in some places stepped in to prevent the sale of such ice.

ONE IN A THOUSAND.

A SPARE man, just touching the middle height, with finely-cut patrician face and complexion of old ivory lighted up with a grave smile, or darkened again with sad, pensive eyes—such was Agostino Bertani, head of Garibaldi's medical staff, surgeon-in-chief to the General's "Mille" and in every sense, one in a thousand! Carlyle has said that Mazzini sacrificed to the revolution one of the finest literary faculties of the century: replace "literary" by "surgical" and the same might be said—with at least no Italian dissentient—of Bertani. A distinguished student and graduate of the Medical School of Pavia, he had barely entered on the career for which nature and culture had destined him when he was drawn by an irresistible force into the tremendous conspiracy which started in 1830, exploded in '48, "causing the thrones of monarchs to quake and the horns of the altar themselves to tremble." In 1854 we find him, in the intervals of professional work, conspiring with Antonio Panizzi, of the British Museum, to aid Garibaldi in releasing the noble prisoners of San Stefano; in 1859, on the outbreak of the war that drove Austria out of Milan, organising and superintending the ambulance of Garibaldi's "Cacciatori delle Alpi"; in 1860 completing with silent celerity the preparations for the descent on Sicily which ended in the triumphal march into Naples of the ever-victorious "Mille"—Bertani being one of the seven who ventured in, under the Bourbon batteries, in advance of the main body; in 1862 tending the wounded lion at Aspromonte, where he assisted Zanetti in extracting the bullet whose presence, four centimetres and a half deep under the lower extremity of the tibia, was so ingeniously proved by Nélaton; in 1867 figuring as "il chirurgo nato di tutti i campi rivoluzionari" (the born surgeon of all the camps of the revolution) in the campaign that culminated in the not inglorious defeat of Mentana; and from the completion of Italian Unity in 1870 till his death in Rome on Friday, the 30th ult., holding an isolated position in the Italian Chamber of Deputies—a Liberal on grounds that "Liberals" did not understand—and busied with his great work on the amelioration of the agricultural classes throughout the Peninsula, the results of which are embodied in his masterly "Codice Sanitario." His papers, it is said, will form a memorable book on what may be called the "ambulance system of the revolution," while filling many a gap and solving many an enigma in the as yet but half-known history of the great epopee in which the outstanding figures are Pio Nono, Victor Emanuel, and Garibaldi. Italy, whose troubles as a constitutional State threaten one day to be neither few nor small, will miss him much—long after the dying out of the regret his loss inspires in the contemporary world of science, of literature, of art, *et quantum est hominum venustiorum*.

THE SENSORY NERVES OF THE SKIN.

DR. ALFRED GOLDSCHEIDER has recently communicated to Dubois Reymond's *Archiv* the results of researches he has made upon the nerves by which sensations of temperature and pressure are conducted. He finds that the skin is not in all parts capable of perceiving variation of temperature, and that some parts can only recognise sensations of cold, other parts only sensations of heat. These, which he terms warm and cold points, are distributed between or amongst each other, but never coincide. Their general arrangement is that they are disposed in chains which pursue a slightly curved course. These chains radiate from certain points which may be termed radiation-points or temperature-centres. The chains of the cold points do not in general coincide with those of the heat points, but these radiation points are identical. The cold points are in all parts of the skin more numerous than the warm points. When the cold points are excited by either mechanical or electrical stimuli a punctiform sensation of cold is experienced, and the opposite sensation is felt when the warm points are stimulated. Goldscheider was able by stimulation of nerve trunks to excite excentric sensations of heat and cold. The temperature points were found to be insensitive to pricks and other punctiform pain excitants. Goldscheider admits, therefore, not only the existence of nerves exclusively devoted to perceptions of temperature, but specific nerves for heat and cold. The sensibility of the surface of the body to temperature presents great topical variations, and is directly dependent in any region upon the number and intensity of the temperature points—that is to say, upon the local wealth of temperature nerves,—and go hand in hand with the distribution of the great nerve trunks. Goldscheider also differentiates in the skin nerves of general sensation and specific pressure nerves. The latter terminate in certain points of the skin which are not only especially sensitive to very delicate contact, but contain also peculiar organs which excite a granular sensation on pressure. The pressure points

Digitized by Google

are arranged after the same fashion as the temperature points, but are in general much more closely aggregated. Both they and the temperature points supply us with information in regard to locality.

MEDICAL SOCIETY OF LONDON.

THE conversazione of the present year, under the presidency of Mr. R. Brudenell Carter, formed one of the most successful gatherings that has ever taken place at Chandos-street. The walls of the large room were decorated with perfect specimens of water-colour art, the property of Mr. J. Orrock, the well-known collector and artist. There were some of William Hunt's that have given to Ruskin's pen some of its most sympathetic and beautiful sentences; these water colours of fruits, though executed more than forty years ago, are by no means "ghosts of their former selves," but even now depict with so much truth the aspect of nature that the eye almost seemed to see the very translucency of the grapes and the exquisite bloom of the plums. In addition to these there were several examples of De Wint, George Barrett, and Cox. Beautiful specimens of Doulton ware, a thermopile with incandescent lamps by Mawson and Swan, microscopic specimens by Messrs. Baker, and the band of the Royal Artillery were provided for the delectation of the visitors. Dr. Douglas Powell's thoughtful and instructive address on the powers of repair and compensation in the economy contained many original suggestions, was pervaded with a subtle sense of humour, and was full of encouragement and hope for those who practise the healing art. The orator considered that other symmetrical organs than the eye were liable to sympathetic disease, and suggested that reparative processes in tissues set up similar processes in symmetrical organs; besides sympathetic disease we have also sympathetic compensation or repair. Dr. Ord proposed and Sir Joseph Fayrer seconded the vote of thanks to the orator, including a desire that the address should be printed and published. To the energy and business capacity of the secretaries, Mr. J. H. Morgan and Dr. S. West, and of the registrar, Mr. Poole, the great success of the evening must be largely attributed.

PITYRIASIS AND PHTHISIS.

EVERY physician is familiar with the cutaneous eruption occurring frequently on the chest and back of phthisical patients, which passes under the name of pityriasis versicolor or chloasma, and the fact that it is due to the presence of a fungus allied to those which cause favus and ringworm is well known; but no one has at present suspected that its presence had any significance, or that it had any real connexion with the essential lesion of phthisis. It was regarded as a fungus which took advantage, so to speak, of the exhausted and debilitated condition of the patient to take up its abode in his skin, and it occurs in other wasting diseases of a similar nature. That it is contagious and can grow on the healthy skin is shown by the story which is told of the French pathologist Lancereaux, who, wishing for a drawing of the fungus for his plates on pathological anatomy, took some skin scrapings in an envelope in his pocket, and was surprised after a time to find a plentiful crop of the parasite not only on his own chest but on that of his wife. But the fungus has now come before us in a new light, as playing a prominent part in the production of tubercular phthisis. According to the researches of MM. Duguet and Héricourt, the results of which were given to the Academy of Sciences on April 19th, certain cases of acute tuberculosis presented no bacilli or zooglœa forms; but when the tissues were treated with potash (10 to 40 per cent.), a delicate mycelium allied to that of microsporon was discovered; and on pushing the inquiry further it was found that this mycelium was more frequently present than the bacilli, being seen not only in the tubercles but also in the neighbouring healthy tissue. Similar mycelial threads can also be found in the expectoration mixed with the bacilli. When the microsporon furfur is cultivated and injected into guinea-pigs and rabbits, these animals become, without exception, tuberculous, and the same result is obtained by insufflation into the trachea of the crusts of pityriasis. Moreover, the cultures of microsporon furfur, of tubercle produced from the fungus, and those from tubercles of man are precisely the same in character. Cultivations can be made in slightly alkalinised bouillon or in milk, when it becomes possible to distinguish an aerobic and an anaerobic element. The former floats at the surface, and at a temperature of from 30° to 38° C. forms a thick membrane composed of bacilli. The latter is found at the bottom of the cultivation-tube as a mass of granulations and mycelium. The polymorphic character of the tubercle bacillus is thus manifest, and the opinion of Spina receives support as to the variety of the forms of microbes in tuberculosis. The whole question is an interesting one, and it cannot be said to be yet settled whether the various forms of low vegetable life to which we assign names are not phases in the life history of one species modified by chemical and physical conditions. The authors regard their discovery as important from the possibility of obtaining an attenuated virus.

INSANITARY BURIAL.

IN our advocacy of burial, as opposed to cremation, in the disposal of the dead, we have always taken for granted that such burial should be subject to sanitary rule. It would seem that this matter does not yet receive in some districts the attention which is its due. An inquiry held at Chorlton, near Manchester, a few days ago, brought out some strange disclosures as to the state of the parish churchyard. Various persons complained of the nuisance caused in the district by the unwholesome condition of the yard, and the sexton's evidence was even more conclusive to the same effect. It was shown that one grave which had been reopened had immediately to be closed on account of the foulness of its contents. On another occasion a body had been buried no deeper than two feet below the surface of the soil. These facts appear to show clearly that Chorlton churchyard has come to be over-filled, while the mention of bones and portions of coffins thrown up from time to time reminds us that a lighter structure than the usual wooden case is required for sanitary burial.

LUNATICS AT THE THAMES POLICE-COURT.

THE "lunatic at large" has a fair field and no disfavour at the Thames Police-court. There he can air his grievances and count on a sympathetic ear into which to pour the troubles arising out of his delusions. A few days ago the worthy magistrate at this court would seem to have held a reception for the victims of mental disease; or was it by chance that two notable specimens of the insane world appeared before his worship with what were euphemistically called "strange applications"? One applicant, a man about thirty years of age, was anxious for advice as to the acquisition of a sum of money to which he believed himself to be entitled, as a recognition of his merit in the invention of the lifeboat now in general use. The amount supposed to be due to him was considerable, the Baroness Burdett-Coutts having headed the list of subscribers with £10,000 or £19,000, we are not clear which, and it is not a matter of much moment. Another applicant, described as "a strange-looking man," was anxious to obtain protection against some persons who were trying

Digitized by Google

to poison or shoot him, and who followed him almost day and night. The "strange-looking man" handed the magistrate a list of the offenders. Mr. Lushington, of course, instantly recognised the first as a case of general paralysis of the insane, and the second as an ordinary case of delusional insanity, with a constantly besetting peril of self-murder or homicide. We are not informed as to the precise means taken for the protection of these two lunatics at large; but there can be no question as to the fact of their having been taken good care of, seeing that in future the intervention of a magistrate is to constitute the all-sufficient safeguard of *proper* treatment for the insane. The magistrate at the Thames Court would not have allowed two dangerous lunatics to leave the court unprotected after so characteristic a disclosure of their diseases.

A NON-TYPHOID PEYERIAN ULCER.

AT the last meeting of the Medical and Physical Society of Bombay, held April 2nd, the President, Dr. H. V. Carter, exhibited six specimens of a form of Peyerian ulcer, which he had not found previously described in current text-books. They had been obtained at necropsies of native patients suffering mostly from fever in the Goculdas Tejpal Hospital, Bombay; and if the most pronounced example were to be regarded as in any sense typical, it would indicate the occurrence, however occasional, of an affection which might not inaptly be termed "Indian enteric fever." Here the patient was a young male Brahman, resident, admitted on the ninth day of illness from the locally so-called "remittent fever," prostrate and anæmic, yet free from diarrhœa, and at no time in the true typhoid state. On the sixteenth day he was suddenly seized with acute peritonitis, and died two days later. The necropsy revealed as coarse lesion only numerous irregular deep ulcers in the ileum, the larger of which were obviously connected with Peyer's patches. In this, as in the other specimens, only some patches and a segment of each were involved (usually near its margin and extending laterally beyond); and elsewhere the lymph-follicles themselves, with adjacent mucosa, even up to the edge of the ulcer, were not especially implicated, the primary lesion being apparently blood-stasis in the submucosa of the follicular areas, where a peculiar abundance and restricted anastomosis of the small blood-vessels normally obtain. Sectional views and other drawings were shown, and it was mentioned that micrococci had been seen within basal blocked vessels and around others at the sides of ulcers, further histological details being reserved for a future meeting. This affection is manifestly different from the catarrhal, peptic, or tubercular ulcerations, and also from genuine typhoid, a specimen of which occurring in a native soldier was shown for comparison; but whether or not it corresponds to what in some Indian museum specimens has been designated "perforating ulcer" of the small intestine remains still uncertain, though there are at the Grant Medical Museum, Bombay, a few such specimens which the author regarded as most probably identical with his own. The ulcers being often small and without much surrounding vascularity, might possibly at times be overlooked; and without close attention, combined with the use of a lens, it might sometimes be difficult to ascertain their real connexion with follicular areas; especially, there being no prior enlargement of the adenoid masses, the relation of the isolated or smaller clusters to the smaller-sized ulcers might not be clearly apparent. Respecting the pathological diagnosis of the larger ulcers as displayed in the case above alluded to, the author quoted as not irrelevant the cautionary remark of Rokitanski (Syd. Soc. Trans., vol. 2, 1849, p. 75) that "an acquaintance with the many anomalies of the typhus process is of such importance that we would not trust the person ignorant of them to judge of a post-mortem examination in a case of acute fever." As to etiology in this preliminary communication, the narrator, dubious as regards any urban "malarious" influence, could only surmise the operation of a "septic" infection different from the "typhoid," though equally pythogenic in its nature and source; considering that the chemical and bacterial components of filth are numerous and variable enough to warrant (comparative experiment upholding) the inference that more than one pathogenous agent may at times be present in the fetid air, water, or soil of a crowded tropical city.

SANITARY IMPROVEMENTS IN IRELAND.

LAST Saturday Mr. Edwin Chadwick, at a meeting of the Association of Public Sanitary Inspectors, referred to the entire neglect of sanitary legislation which had resulted from the devotion of public attention to the exciting political events of the last few years, and pointed out that the most "mud-hovelled" districts in Ireland were the most ravaged by epidemics, and were most marked by crimes of violence and passion. He proposed, as a measure of sanitation, the compulsory subsoil land drainage, and, in some instances, surface drainage, of 150,000 farms in Ireland, which were referred to by the Registrar-General as being too small for the occupiers to live upon them without resources from England, which were now closing against them. In England the voluntary adoption of this measure of sanitation had repaid itself in ten years by a profit of 10 per cent., and Ireland, having a wetter climate than England, was in greater need of this assistance. From the accounts published of Mr. Chadwick's address it is not clear whether he proposes that this work should be undertaken by the State. The great difficulty in Ireland is the want of capital, and though we do not doubt that the investment of money in improving land would make ample return by reducing sickness and mortality, we are afraid the condition of the country is not such as to encourage capitalists to anticipate that they would find a very safe investment in Irish land improvement schemes.

EXTRAORDINARY CÆSAREAN OPERATION.

La Gazzetta degli Ospitali of the 2nd inst. reports the convalescence of a patient who performed the Cæsarean operation on herself on March 28th ult. These are the facts: A peasant woman of Viterbo, aged twenty-three, illegitimately pregnant at full term, at dawn on March 28th last, with a common kitchen knife (*con un coltellaccio da cucina*) opened her own abdomen on the right side. The wound, five inches in extent, was oblique from within outwards and from above downwards. The woman then opened the uterus in the same direction, and endeavoured to extract the fœtus. As this was at full term it could not be readily removed. The mother first drew out an arm and cut it off. To still further reduce the bulk she amputated the head, and then completely emptied the womb, extracting the placenta. She bound a broad bandage very tightly round her body, hid the fœtus in the straw mattress, dressed herself, attended to some domestic duties, and on a cart went into the city of Viterbo to show her sister a cloth bathed with blood, as a menstrual proof of her not being pregnant. On returning home, having walked about for five hours, she vomited and fainted, and the parents called in Drs. Serpieri and Baliva. Thirteen hours had elapsed from the infliction of the wound, and through it the bulk of the intestines had been protruding for six hours. The medical attendants having satisfied themselves of the complete reduction of the emptied uterus, performed abdominal toilette as well as was practicable, replaced the viscera, introduced a drainage-tube, and sutured the wound. The evening temperature was 37·7°; lochia

Digitized by Google

natural per *vias naturales*. The woman stated positively that she had had no accomplices. No unfavourable symptoms supervened. The deep wound healed, and was only superficial on the 15th of April, the eighteenth day after the self-performed Cæsarean operation. The countrywoman of Mutius Scævola has proved that the fearless bravery of the Romans lives.

THE OPIUM TRAFFIC.

THE recent discussion in the House of Commons on the opium traffic, while it cannot be said to have added much to our knowledge of the injury inflicted by the free use of this drug, has brought into small compass the economic difficulties which surround the question of its legal prohibition. It is hardly necessary for us in these days to give in detail our professional view of the proper use of opium. On one point, however, we must say something. Sir R. Temple, in his able criticism of the motion introduced by Sir J. Pease, said that "the opium case ran on all fours with the consumption of alcoholic liquors in this country; the question throughout was merely one of temperance." With this opinion, supported though it may be in a way by scientific testimony, we cannot agree. Alcohol, as usually consumed, is rather a luxury than a poison in the ordinary sense. Herein lies its insidious danger. Opium is from first to last a drug and a poison. Its proper place is in medicine, and there only. In turning from the purely medical to the legislative aspect of the subject, we may perhaps be expected to adopt the view of Sir J. Pease—with which, indeed, we have much sympathy,—and to require the direct prohibition of the opium culture, save to the extent required for medicinal purposes. Were it not for the financial difficulty, apparently insuperable at present, and for some taint of injustice which attaches to such a course, we might even go thus far. As matters stand, however, the opening clauses of the motion, which advocate official discouragement rather than prohibition, alone seem to mark the lines of sound policy. As a governing people, we are fairly entitled to diminish, by every legal means, the demand both within and outside of India. If China has been denied her legitimate embargo and desires to impose it, we should allow her to prohibit imports of foreign opium. Within our Indo-Burmese empire, again, we should cease to subsidise opium producers, and should impose necessary restrictions on the sale of the drug. The question of compensation has been carefully gone into in the late discussion, and, indeed, it seems to us to have been much overdone in the speech of Mr. McIver. Should such changes in the way of restriction as we have indicated be gradually carried out, time being allowed for the substitution of other crops for that of opium, the aggregate loss of cultivators and of the Indian Revenue Office will not be likely to demand a ruinous sum in compensation. It is by such remedial measures, we believe, and by stimulating as far as possible a healthy dread of the evils of opium-taking among the populations of India, that we may best atone for past errors of judgment with regard to this much-mismanaged drug.

INOCULATION OF A CONDEMNED CRIMINAL.

THE following is a summary of an account in the *New York Medical Record* of the first attempt to use a condemned criminal for the solution of an important and scientific question at the Hawaian Islands. It appears that, more than two years ago, the Government procured the services of Dr. Edward Arning for the purpose of having a thorough and scientific study made of leprosy. Attempts were made to cultivate the bacillus lepræ, which is uniformly found in great numbers in the diseased parts, but not in the blood, by Koch's method, using various media, but without success. Numerous inoculation experiments upon lower animals were made, but, although the bacilli would grow at the points of inoculation for a long time, the animal never became infected. At last Dr. Arning obtained permission to make an inoculation upon a condemned criminal, whose sentence was commuted to imprisonment for life. With the convict's written consent an inoculation of leprous matter was made in his arm, and bacilli were found in the sore or the scar up to fourteen months after the operation, no constitutional symptoms being observed. One further observation of importance was made by Dr. Arning: he found that in putrid leprous tissues, and even in the body of a leper who had been dead for three months, the bacilli were found in great numbers. This seems to bear against their specific pathogenetic function. Owing to difficulties with the Health Board, it is stated that it is highly probable Dr. Arning will be obliged to discontinue his work of research. With respect to the cultivation of bacillus, Dr. Neisser of Breslau appears to have been more successful than Dr. Arning, for he has recently stated that in a few cases he has observed an exceedingly slow growth, and he also claims to have recognised spores, which the Hawaian observer has, so far, failed to do.

THE RADICAL CURE OF VARICOCELE.

To the large number of operations which have been devised for the cure of varicocele yet another has been added by M. Richet, of the Hôtel Dieu. It is described in the *Revue de Chirurgie* for April by Mr. Picqué, who is disposed to laud it. The vas deferens is first separated from the bundle of veins to be obliterated and held out of the way by a thread of copper wire passed through the scrotum in an armed needle. The veins and the fold of scrotum over them are then grasped by the blades of forceps heated to a red heat, such as M. Richet uses for the destruction of hæmorrhoids. A wound of some size is left, and cicatrisation is obtained in about three weeks. M. Picqué argues that excision of the veins is the best of all the many operations for varicocele, but that it should only be undertaken by those who are quite familiar with the aseptic treatment of wounds. In cases where the surgeon is not confident of his ability to keep the wound aseptic he recommends Richet's operation. We cannot join in such advice. Richet's operation appears, from the description given of it, to be a very rude method of obtaining a result more easily, more quickly, and better obtained by other means.

SANITARY PRECAUTIONS AT BRINDISI.

THE appearance of cholera at Brindisi, though happily thus far attended with no very serious mortality, has already brought out the first signs of panic and ruffianly excess which were only too visible among the poorer Italians during a former visitation. We would fain hope that the scenes of disorder then witnessed may not again be suffered to occur. Personal and household cleanliness, a ready access to materials for disinfection, with such advice as to the management of water-supply as a municipal or parochial authority can easily communicate, will do more to arrest the subtle enemy than any armed exclusiveness of a cordon or a village mob. Practitioners and nurses live in the midst of the contagion, yet by observing such reasonable care they commonly escape its influence. We need not, therefore, despair of seeing even the more ignorant of the public follow their example, and regard this disease no longer as a destroying angel, but as a preventable pest. In the case of Brindisi and other ports the establishment of floating hospitals, of which we have as yet seen no mention, is a measure worthy of consideration. Notwithstanding

Digitized by Google

that obstacles exist in the absence of a tide or a considerable river, and the tendency to sickness in cholera which would not be lessened by exposure to rough weather, there are obvious advantages in the scheme if these difficulties can in any way be met.

JUVENILE MUSCULAR ATROPHY OF THE EXTREMITIES.

AT the séance on April 23rd of the Société Médicale des Hôpitaux, M. Joffroy gave an account of a disease which must find a place in our future nosographical literature. It is not exactly new in the sense that this was the first case described, for attention was first called to it by Charcot and Marie some months back. These observers collected the cases observed by themselves and others, which brought the number recorded up to the present time to about thirty. It is possible that as the existence of such a disease becomes more widely known cases will be more common. The disease commences in an atrophy of the muscles of the foot in an infant or young child, and it is very common for several members of the same family to be affected. In an account given by Eichhorst there were ten members in the same family thus afflicted. The atrophy affects also the muscles of the legs, and after a varying period of time attacks the hands and the arms, but never the muscles of the face or trunk. The atrophying muscles often present fibrillary contractions and cramps, and give the electrical reactions of degeneration. The case to which M. Joffroy referred, but which he was unable to exhibit to the Society, as it was a private patient, is typical of the disease. The patient was a girl, who enjoyed good health till the age of five years, when, after a slight attack of scarlatina, it was noticed that she walked with difficulty, and seemed to tumble much more than other children at play. By degrees the foot assumed the shape of talipes equinus, and it was evident that the muscles were wasting; the skin over the feet was cold and red, the sensibility normal, but the muscles failed to react to the faradaic current. Such was briefly the condition of the patient for five years, when, without any other symptom, her hands seemed to be becoming weak, and in three months' time the atrophy of the thenar and hypothenar eminences and interosseous spaces was well marked, and the movements became very limited; she could not play the piano or write; but under treatment she improved, and for the last six months there has been no evidence of the progress of the disease.

SURGICAL CONGRESS IN ROME.

ITALY is making rapid strides towards regaining the high position she held at the Renaissance, and in the century succeeding it, in the medical sciences. Of this the most recent of her congresses—that of Surgery just concluded in Rome—furnishes ample proof. Among the communications which attracted most attention at its sittings were those of Professor Antonino D'Antona of Naples on Ovariotomy, an operation in which he has had a brilliant series of successes, and of Professor Antonio Ceci of Genoa on Extirpation of the Spleen. The subject of this latter operation was a poor girl seventeen years of age, whose splenic enlargement reached to one-fifteenth of the weight of the entire body, being the most bulky of those hitherto extirpated without being followed by the patient's death. Professor Ceci's operation was quite successful, and the girl, after a month in hospital, is now in good health and fit for service. This is the seventh case in which the spleen has been extirpated in Italy, and the second in which it has been done successfully. Professor D'Antona also read a paper on Excision of the Kidney, and produced quite a lengthy *catena* of cases in which the patients had recovered with all the renal functions adequately discharged by a single kidney. These papers will shortly be accessible in a revised form to the profession and the public, and will doubtless be hailed as an earnest of the good work in operative surgery by which Italy is now resuscitating her former and better self.

THE COLONIAL AND INDIAN EXHIBITION.

THE Colonial and Indian Exhibition, which, unlike its predecessors, is imperial and not international in character, was most successfully opened by Her Majesty the Queen in state on Tuesday morning last. A beautiful May day, and the most welcome absence of the easterly winds which have so long asserted themselves, contributed to render the occasion a perfect one. The Queen was received at the main entrance by the Prince of Wales and the Executive President, and the procession, having been formed, proceeded through the building and gardens to the Albert Hall; here, after the singing by the choir of the National Anthem, and an ode written for the occasion, by special desire of the Prince of Wales, by the Poet Laureate, and set to music by Sir A. Sullivan, in which Madame Albani, a Canadian, appropriately took the solo part, an address was read by the Prince of Wales, to which Her Majesty replied, and the Exhibition was then by command of the Queen declared by the Lord Chamberlain to be open.

FALSE JOINT FROM A FRACTURE IN INFANCY.

M. BERGER recently showed a very interesting specimen at a meeting of the Société de Chirurgie of Paris. It consisted of the lower limb of a man fifty-seven years of age, who had received a fracture of both bones of the leg when only nine months old. This was followed by the formation of a false joint which prevented the man from walking. The upper fragments of the tibia and fibula were rounded off, and fitted into cup-like depressions on the lower fragments. The adjacent surfaces were eburnated and coated with dense granulation tissue (not cartilage), and were held together by a capsular ligament continuous with the periosteum and lined by a true synovial membrane. The knee and ankle joints were not ankylosed, as is often the case in such conditions. The whole limb was undeveloped, as the following measurements on the two sides show:—Length of foot 18 centim. as compared with 24 centim.; length of patella 5·0 centim., instead of 6·0 centim.; length of femur 36 centim., as against 39 centim. The muscles were not degenerated; the nerves to the naked eye were healthy; but the skin over the toes was the seat of anæsthesia and local asphyxia. The question raised by M. Berger was, whether these developmental changes were the results of the "false joint," or whether they and it were both due to one obscure trophic affection.

SANITARY FURNITURE.

THOUGH so much has been written concerning domestic hygiene, no general principle has yet been promulgated to govern the construction of furniture. Dr. Gustav Jaeger, however, seeks to supply this want. Admitting the soundness of the theory on which he founds his sanitary clothing reform, Dr. Jaeger further urges that dead wood, as well as cotton, linen, and other vegetable matter, retains its powers of absorbing noxious animal exhalations. These the living plant digests, but the dead fibre or wood only harbours such poisonous gases for a time, and then throws them off again when there is a change of temperature. For instance, if a room is closed for some days, an unpleasant odour will be noticed on re-entering. This is especially apparent in German government offices, where the innumerable shelves and pigeon-holes are made of plain unvarnished wood. Sanitary furniture must there-

Digitized by Google

fore be rendered non-absorbent by carefully polishing or painting all the woodwork, both inside and outside; and the same rule applies to the flooring, wainscoting, &c., of all habitations. A room may be cleaned and purified after infectious diseases; but very powerful fumes are required to reach the interior of a closed drawer. From a sanitary point of view, the inside, the unseen, the back parts of furniture equally require to be treated with varnish, paint, or other substance, to render the wood non-porous. In practical Germany, sanitary furniture has become an article of commerce, and in England also we have recently inspected some such furniture. To carry out the above principles, the wood employed was prepared beforehand and rendered non-porous. This process, when applied to furniture made exclusively of wood, such as wardrobes, chests of drawers, sideboards, &c., involves an extra cost of not more than 5 per cent. Old furniture may also be rendered sanitary for a small outlay, by covering the interior and unseen parts with a substance that will close the pores. The "unpleasant feeling" sometimes noticed by those who use upholstered furniture is due to the odorous exhalations stored in the vegetable fibre, and which vitiates the atmosphere of ill-ventilated rooms. The polished wooden seats of our ancestors are preferable, unless the chairs and couches are stuffed and covered with materials of pure animal fibre, dyed with fast wholesome dyes; and this, if inoculated, would necessitate an extra cost of about 10 per cent. All textile material not of animal fibre, such as the stout webbing required underneath upholstered seats, is soaked in a solution which forms an impervious coating and prevents absorption. Carpets and curtains made or adulterated with vegetable fibre are obviously incompatible with this definition of sanitary furniture. White window-curtains, we are assured, will, if examined closely, emit a sour odour when they have been in use for a little time. A woollen curtain would give rise to no such unpleasantness, even when exposed in an inhabited room for a much longer period. Thus, to sum up, Dr. Jaeger maintains that all woodwork should be rendered non-porous, the walls should be painted or the paper varnished, and the upholstery, bedding, carpets, rugs, and curtains should consist of animal fibre sanitarily dyed.

CEREBRO-SPINAL MENINGITIS.

A SERIOUS epidemic of cerebro-spinal meningitis occurred in Gottenberg in 1883. Dr. P. Silverskiold had excellent opportunities of studying the nature of the disease in fifty-eight cases, which he observed with great care and minuteness. After making many bacteriological experiments in pursuance of Pasteur's method, he came to the conclusion that the disease is not due to bacteria. He publishes in the *Eira* the result of his experience. In his opinion the disease arises from malaria, and is not the result of any excessive physical exertion or mental emotion. He founds this belief on the topographical situation of Gottenberg. On the right bank of the river lies the district of Lindholmen, in the vicinity of which are large expanses of marshy ground. Under ordinary circumstances these marshes are covered with water and comparatively innocuous, but during a prevalence of strong east wind they are completely bare; during the west winds, therefore, the marshes are covered, but during the east winds, not only are the marshes bare, but the harbour and the canals are also affected. This occurred in 1883, when there was an unusual prevalence of strong east winds, accompanied by cold dry weather. The water in the harbour fell so low as to deter ships from landing at the pier, and left a large tract of mud; the marshes were laid bare, the canals were so dry that boats could not pass along them, and the sewers, which are ordinarily covered with water, were disclosed to view. Such a large mass of decaying animal and vegetable matter thus exposed to the air could not fail to be a grave danger to health. Those employed in the open air, especially those whose occupations led them to work at the harbour or near the marshes or canals, were most susceptible to infection. On the recurrence of the west winds the epidemic slackened; but on the east winds reappearing, the number of victims increased. Those who lived near the marshy lands were the first attacked; the disease began in separate parts of the town and neighbourhood, and in no case appeared to have been carried by contagion. The complications and symptoms form a long and startling list. From the commencement of the disease the patient loses all appetite, and this disinclination to food continues during the whole course, and even in convalescence. The treatment Dr. Silverskiold found most useful was local bleeding. Choral he considered should be avoided; but morphia he regarded as invaluable.

SARCOMA OF THE RIBS, INVOLVING THE DIAPHRAGM.

M. HUMBERT records, in the April number of the *Revue de Chirurgie*, the case of a woman, twenty-one years of age, who was admitted into the Hôtel Dieu in 1883, with a sarcoma growing from the eighth and ninth ribs on the right side. M. Peyrot attempted its excision, and in so doing wounded the pleura and caused a pneumothorax. He therefore contented himself with removing the superficial part of the mass. The wound healed, and in December of the same year the patient came under M. Humbert's care. The tumour was then the size of a chestnut, ulcerated in the centre, and there were signs of pleural effusion. A second operation was performed; the surface of the tumour was freely exposed, and the seventh, eighth, and ninth ribs, which were involved in it, were divided at each side of it, nine centimetres of the bones being removed. The tissues in the sixth and ninth intercostal spaces were then divided, and the mass removed. The pleural cavity was opened, and a considerable quantity of fluid escaped from it. On cleansing this cavity a hole was discovered at its lower part; this was enlarged and explored, when the liver, colon, and coils of intestine were clearly seen. This wound in the diaphragm was closed with five catgut sutures, and then the superficial structures were sutured. For a day the patient was very collapsed, but convalescence proceeded without complication, and the wound healed except a small sinus at the lower part. Around this sinus a recurrence of the growth took place, and in December, 1885, M. Pozzi performed a third operation, under which the patient sank. The case is mainly interesting as an instance of a wound of the diaphragm which united without any inflammation of the abdominal structures. Considering the impossibility of giving complete rest to this muscle, such a result is particularly satisfactory. Where tumours are known to involve the diaphragm their removal should not be attempted; but if during an operation this muscle is injured, it should be carefully sutured, as in this case.

HYDROPHOBIA IN HOLLAND.

THE Minister of the Interior in Holland has offered to send to Paris at the expense of Government some persons bitten by rabid dogs in Overijssel; the sufferers have, however, all refused to avail themselves of the offer. A man named Leendert Jooren, of Made, who was bitten by a mad dog has consented to undergo the operation of inoculation, and has been sent to Paris. The bodies of the condemned dogs have been sent to the Government Veterinary School for anatomical examination. The law concerning muzzles is strictly enforced, a large district coming within its operation—namely, the whole of North Brabant. The condemned cats and dogs are to be burnt.

ARTHROTOMY FOR LOOSE BODIES IN JOINTS.

M. KIRMISSON recently presented to the Société de Chirurgie two cases of loose bodies in the knee-joint for which arthrotomy had been successfully performed. He assented to the view that some of these bodies are truly traumatic in nature, being broken off from articular cartilages by violence; while others, the greater number, are pathological in origin. The arrangement of the cells in the cartilage usually allows it to be determined whether a given "loose body" is traumatic or pathological in origin, but in some cases this point cannot be cleared up. M. Kirmisson suggested that the use of a drainage-tube was not necessary after arthrotomy for the removal of such loose bodies, and he also advocated including the synovial membrane in the sutures. Both these points excited considerable discussion. Some surgeons were strongly in favour of abandoning the drain; others argued that it was harmless, and might prevent serious mischief. Cases can be cited in favour of each view. Where the arthrotomy is very simple, and there is no synovial effusion, a drain appears to be unnecessary, and may be dispensed with; but if the operation be prolonged, complicated, and attended with much manipulation of the synovial membrane, or if the joint be the seat of a chronic effusion, it is much safer to insert a drain. Should a drain not be used, it is better not to insert sutures; any exudations then have a free exit from the wound; while if the wound is closed, tension may be excited. The best form of suture would be a "buried suture" of the synovial membrane preliminary to the closure of the superficial wound.

THE CHAIR OF PHYSIOLOGY IN ABERDEEN.

AT the opening of the summer session in Aberdeen, Professor Struthers spoke a few kind and well-chosen words on the appointment of Dr. McWilliam to the chair of Physiology. He traced his career from the class to the chair, and praised him not only for regular and steady work in the daily routine of a student's life, but for acquiring early the love of science and the desire to enlarge its boundaries. He magnified the uses of a university and the office of the professor, which were meant for more than the communication of everyday knowledge. The university should stimulate research and original investigation and the professor who did not show his power in these ways had not justified his appointment.

INSPIRATION OF COLD AIR IN FEVER.

THE effect of breathing cold air has been made trial of in St. Petersburg by Dr. Ivan Voitekevich on a number of patients suffering from various pyrexial diseases, enteric fever, croupous pneumonia, pleurisy, &c. His method of proceeding was to take the pulse and respiration, and also to note the temperature in the rectum, axilla, and on the surface of the chest, and immediately afterwards to apply to the patient's face a mouthpiece connected with a tube communicating with the external cold air, directing the patient to inspire deeply. The mouthpiece was removed during expiration and replaced for each inspiration. The "sittings" were usually continued for from twenty to thirty minutes, but were stopped at once in cases where the patients seemed exhausted or faint, which, however, very rarely happened. The "sittings" were usually repeated morning and evening for several consecutive days. The temperature of the ward was always noticed, and was usually between 60° and 70° F. The external temperature, which was that of the inspired air, was, as a rule, about 20° F. lower. After the "sitting" the observations on the pulse, respirations, and temperature of the patient were repeated both immediately and after the lapse of one and two hours. The results obtained showed that the temperature was lowered but slightly and for a very short time, but that a considerable diminution was produced in the frequency of both pulse and respiration. The patients, too, felt better and slept longer, but this was but temporary. The cold air appeared decidedly to lessen the bronchial catarrh from which they suffered. No evil effects were observed, but, on the contrary, the cold air treatment appeared to act in a beneficial manner.

INTERNATIONAL CONGRESS ON HYDROLOGY AND CLIMATOLOGY.

WE have received from the Foreign Office papers relating to a proposal to hold next October in Biarritz an International Congress on Hydrology and Climatology; the Congress is to be presided over by the French Minister of Commerce and Industry, and the French Government are anxious that members of scientific societies in this country should assist. The Congress will be divided into three sections, and papers are invited on scientific hydrology, medical hydrology, and climatology. The proceedings will last from Oct. 1st to the 8th, and at its close the different thermal and sanitary stations in the Pyrenean district will be visited.

PUERPERAL FEVER IN SPITE OF ANTISEPTIC PRECAUTIONS.

M. HERRGOTT of Nancy, in a communication to the Paris Academy of Medicine, mentions the cases of two women who had been confined in the same ward. In spite of the employment of the most rigorous antiseptic measures, one, who was greatly depressed physically and morally, was attacked by puerperal fever, and succumbed in three days; while the other, who had a very severe labour, entirely escaped the infection. From these facts he deduces the suggestion that, however valuable and true the doctrine of microbes may be in the generality of cases, it is not capable of explaining all the facts of infection. "Too absolute, too general rules lead observers to neglect an essential element in diseases—the patient."

ANOMALOUS KIDNEY.

M. CARTIER describes an anomalous case of kidney formation in a female patient aged twenty-three, who died of fever at the Hôtel Dieu, at Poitiers, in February. The two kidneys were joined in front of the vertebral column by their inferior extremities, forming a kind of horseshoe, embracing the spine. The junction was formed by an intermediary body, whose tissue was of a renal character, and which appeared to be a third renal organ. In addition to two ordinary renal arteries, veins, and ureters, there were three supernumerary arteries, one to each lateral part of the horseshoe and one to the centre or third kidney.

OUR CHANGEFUL CLIMATE.

ONE day in last week the thermometer rose 30° and fell 27°, all in twelve hours. This is an illustrative example of what the weather can do in this country, and collaterally—so far as those who escaped injury are concerned—the episode affords excellent proof of the adaptability of the English "constitution" to a changefulness which not many of the inhabitants of more equable climes could with impunity undergo. Whatever the weather may be for some five or six weeks to come, no prudent person should venture to lay aside winter clothing altogether for the attire appropriate to summer. "Cast not a clout till May be out," and even then make any desired change discreetly, for "fickle as the wind" is a proverb which has more than metaphorical force in England, and which it is well all who value their health should lay very practically to heart.

DEATH OF TWO PROFESSORS IN HAVANA.

THE death is announced of Dr. don Joaquin Barnet y Ruiz, Professor in the Faculty of Pharmacy of the Royal University of Havana in Cuba, caused by extensive burns produced by the ignition of a quantity of ether in the laboratory. Dr. Planellas Llanos, Professor of Botany and Zoology in the Faculty of Sciences in the same university, has also lately died from illness. He was the son of the present Dean of the Faculty of Sciences in Barcelona, and was a knight of the Order of Charles III. *La Enciclopedia*, a Cuban medical journal, lamenting his premature decease, refers especially to the practical character of his teaching, and the improvements which he made in the botanic garden, which is now in a thoroughly satisfactory condition.

TENDON-GRAFTING.

A BOY, aged fourteen, cut himself in the hand and divided both flexor tendons of the middle finger. Thirteen months later he came under M. Peyrot's care. There was then complete inability to extend the last two joints of the finger. An operation was undertaken. It was impossible to approximate the divided ends of the tendons, so a piece of a young dog's tendon was interposed between them. Unfortunately the wound suppurated, but cicatrisation took place and partial success was attained. The finger could be semi-flexed, and was constantly held partly flexed and therefore less exposed to injury than before; but the tendon was adherent to the scar. There seems to be no doubt that the engrafted tendon is really united to the boy's tendon.

FOR the vacant Chair of General Pathology in Insbruck the names of Dr. Gärtner, assistant to Professor Stricker in Vienna, and Dr. Lowit, assistant to Professor Knoll in Prague, have been proposed.

PROFESSOR WINTER is about to retire from the editorship of *Schmidt's Jahrbücher*, with which he has been connected for thirty-six years. His place will be filled by Drs. Mobius and Dippe of Leipsic.

M. RANVIER has been elected "membre titulaire" in the Pathological Anatomy Section of the Paris Academy of Medicine, the unsuccessful candidates being Voisin, Grancher, and Hanot.

A CONGRESS of medical practitioners and workers in the field of natural science is to be held in Christiania on the 12th of July.

DR. F. BESSEL HAGEN has been appointed to the charge of the Surgical University Polyclinic in Heidelberg.

M. PASTEUR has just been appointed a Grand Cross of the Brazilian Order of the Rose.

PRAGUE is reported to be suffering from a severe epidemic of typhoid fever.

THE REMOVAL OF DUST.—On the 28th ult., at the meeting of the members of the Wandsworth Board of Works, attention was drawn to the fact that during the last four weeks the number of complaints from householders as to the non-removal of their dust was as follows:—Battersea, 215; Clapham, 30; Putney, 109; Streatham and Tooting, 128; Wandsworth, 12. It was very justly considered disgraceful that there should be in four weeks 494 complaints in a district where the sum of £9600 per annum is paid for clearing the dust, and a committee was appointed to take immediate action in the matter.

THE GERMAN MEDICAL CONGRESS.

THE fifth annual meeting of the German Medical Congress took place at Wiesbaden from April 14th to 17th, under the presidency of Professor Leyden of Berlin, in succession to the late Professor von Frerichs.

In opening the proceedings, the PRESIDENT alluded to the aims of the Congress, and the connexion between medicine and science, pointing out that in the direction of therapeutics many problems awaited solution, and here experience was of chief value, corrected, confirmed, or modified by fresh observations.

The first subject discussed was the Operative Treatment of Pleural Effusion. It was opened by Dr. O. FRAENTZEL (Berlin), who pointed out that Trousseau's dictum upon the indications for such interference remained good at the present day. In the case of sero-fibrinous effusions such indications were (1) imminent danger to life, and (2) a large amount of effusion—viz, when in the sitting posture the upper level of the fluid reaches at or above the third rib. He advocated postponement of paracentesis until pyrexia had moderated or disappeared, delaying usually to the end of three weeks, occasionally to the end of a fortnight, but rarely resorting to it earlier, these latter cases being mostly of unfavourable prognosis. At the same time he recognised the evil of delay beyond three weeks. He objected to the dorsal puncture, owing to the thickness of the chest wall and the tendency for fibrine to accumulate posteriorly, but preferred a site midway between the mammillary and axillary lines, in the fifth interspace on the left side, and fourth on the right. Aspiration rendered the operator independent of the influence of lung-pressure in regulating the amount of fluid withdrawn; but not more than 1500 cubic centimetres (i.e., about 50 oz.) should be taken. He described the various precautions necessary, and stated that he had never seen a case of sudden death during paracentesis, nor the supervention of acute pulmonary œdema (the "albumineuse expectoration" of the French), and he attributed the absence of these results to the limitation in the quantity of fluid removed. He has frequently tapped for hæmorrhagic effusion, with good result, even in tubercular subjects; but if there is much blood he does not aspirate, and never removes more than 500 cubic centimetres. In purulent effusions, if no absorption take place after aspiration, a free opening must be made, the site of election being the same as that for aspiration given above. In most cases rib-resection is necessary. After evacuating the sac it is washed out with a solution (½ per cent.) of common salt, and a drainage-tube or metal cannula inserted, the thermometer being taken as the guide for further interference. He spoke also of the treatment of pneumothorax.—Dr. WEBER (Halle) followed, stating that paracentesis was absolutely indicated in cases where the intra-thoracic pressure hampered the circulation, as well as in all purulent and putrid effusions. In complicated cases operation could only be palliative. He would not delay interference too long; formerly, in cases of sero-fibrinous effusions, he waited for subsidence of inflammatory symptoms, but found greater risk of encountering such sequelæ as pulmonary compression, &c., and therefore resorts now to puncture within six or five days with far better results. In serous effusion it suffices to use simply a long tube to act as a syphon. He insisted on the value of exploratory puncture, bearing in mind that the fluid is often clearer and thinner in its upper layers than at lower levels. In empyemata he always employs resection of ribs, and washes out the cavity first with a solution of sublimate (1 in 5000) and then of boracic acid (3 per cent). In children a cure may be obtained in two or three weeks.—Dr. FIEDLER (Dresden) described his hollow needle and syphon-tube, and stated that he had quite abandoned the use of the aspirating syringe. He agreed with Fraentzel that interference should be delayed for three weeks.—Dr. FINKLER (Bonn) pointed out that in less recent effusions it may be absolutely necessary to use the stronger force of the aspirator-syringe, and in certain cases would combine aspiration with washing out of the sac.—Dr. LITTEN (Berlin) agreed with Dr. Weber that paracentesis should be done early, and that the presence of fever was no contra-indication; but he has seen the lung re-expand after an effusion has lasted for twelve weeks. He adopts partial resection of neighbouring ribs in empyema.—Professor JÜRGENSEN (Tübingen) said it was a great advance that all

Digitized by Google

empyemata were now radically treated; but he mentioned the liability to amyloid disease in long-continued cases of drainage. He doubted the statement that tuberculosis does not give rise to simple pleurisy.—Dr. HEUESNER (Bremen) uses a cannula and long tube in preference to the aspirator, owing to the fear of increasing the negative pressure, which may cause too great a flow of blood to the thorax.—In reply, Dr. FRAENTZEL said that in tubercular subjects he would only resort to the radical operation as a final measure. The frequency of injections of empyema sacs varied with the case; sometimes they may be needed two or three times a day, in other cases only every two days. It was often not possible to do without rib-resection.—Dr. WEBER added that, except in hæmorrhagic cases, he allowed as much fluid to flow as possible, and did not regard coughing as an indication for discontinuance. He was, on the whole, so contented with present methods as not to desire anything better.

Dr. BRIEGER (Berlin) read a paper on Ptomaines, asserting that one should rather seek to learn the chemistry of bacteria than to discover new forms. He described and demonstrated a large number of poisonous agents which he had isolated in various infective diseases (mussel-poisoning, staphylococcus aureus and pyogenes, typhus, &c.).

Dr. FICK (Wurzburg) read a paper on Variations in Ventricular Blood-pressure in Morphia Narcosis, as estimated by means of an apparatus he has devised. In a dog deeply narcotised by morphia he found a peculiar change from the normal, where the curve suddenly rises in systole, remaining high until the end of systole, when it as suddenly falls to the abscisse, where it remains throughout diastole. Instead of this, in morphia narcosis there is during diastole a slight rise; and this must be attributed to a secondary incomplete systole. Sometimes the diastole is interrupted by several such irregularities of the curve. The phenomenon is explained by morphia interfering with the systole so as to render it abortive; and as these abortive contractions do not suffice to open the valves, they are not registered in the arterial pulse.—Dr. BINZ (Bonn) welcomed the paper as a valuable contribution to pharmacology and as opening the way for other researches. It showed also that morphia is a cardiac poison.—Dr. RIEGEL (Giessen) pointed to the analogy of the phenomena with the pulsus bigeminus and alternans.—Drs. v. Busch and Auerbech also spoke.

Dr. STINTZING (Munich) read a paper on Methods of Electro-diagnosis, in which he advocated the use of Edelmann's galvanometer and his own "unit-electrode" for the purpose of more completely estimating the results of faradaic and galvanic reactions.

Professor ZIEGLER (Tübingen) contributed a paper on the Inheritance of Acquired Pathological Properties. He contended that acquired deformities and diseases are not inheritable, and in support of this referred to the process of impregnation, wherein there is a union between nuclei of the paternal and maternal organisms. Since these nuclei must be regarded as the carriers of inheritable properties, it is very unlikely that acquired properties could be transmitted. Just as difficult is it to accept Weisman's notion of development of generations of germs from an inheritance of acquired disease. It is a fact that a mental disease acquired by traumatism or intra-uterine disorder is not transmitted by an individual to his posterity. Brown-Séquard, in his experiments on inheritance, produced epilepsy in guinea-pigs; but these animals are specially predisposed to nervous disease on the slightest irritation, and it is possible that infection played a part in these experiments. According to Ziegler, malformation and acquired disease are to be referred to primary variations in the germ. These may arise by the union of ill-adapted sexual germs, by derangement of the process itself, and by injury of the sexual germ proceeding from the organism (as in alcoholism, old age, &c.)

(To be continued.)

THE GERMAN HOSPITAL.—On the 5th inst., the forty-first anniversary dinner of the friends and supporters of this institution was held, under the presidency of Prince Christian. It was stated that during last year the number of in-patients at the hospital was 1721, and the total benefited during that period was 25,353. The guests numbered 220, and during the evening subscriptions and donations amounting to £3672 were announced by the secretary.

INDIAN HEALTH STATISTICS.

No. II.

THE average number of prisoners confined in the gaols of India during 1884 was 85,496, a number estimated to be in the proportion of 4·3 per 10,000 of the general population. The admissions into hospital among them were 1025, the deaths 29·11, and the daily sick 36·9 per 1000 prisoners. This shows an increase in the cases, but a decrease in the deaths, compared with the preceding year. The prisons of Bengal were the most unhealthy; those of Madras showed much the lowest death-rate, amounting to only 20·55 per 1000; and those of Bombay furnished the lowest ratio of admissions and daily sick. The great excess of cases in Bengal was from fevers, dysentery, and diarrhœa, and the same diseases, with those of the respiratory system, were the causes of the high rate of mortality in Bengal and Bombay. In the latter the death-rate from respiratory diseases was as high as 9·58 per 1000, while in the Madras Presidency it was only 2·44.

Although there has been a decrease in the general mortality of the prisons, some of them still show an enormous death-rate. Thus, omitting all prisons with an average of less than 100 prisoners, we find that in Bengal, at Rungpore it was 256·5 per 1000, at Banda 156·8, at Jalpaiguri 156, at Mymensingh 148·9, at Chybassa 121·6, at Rajshahai 109·5, at Bogra 107·1, at Purneah 104·2, and at Almora 102·8, the principal cause of death in all being dysentery and diarrhœa. In the Bombay Presidency, the only gaol in which the rate exceeded 10 per cent. was at Nara, where it was 108 per 1000, half of the deaths being from respiratory diseases, and the other half equally divided between fevers, dysentery, and diarrhœa. In British Burmah the mortality in the Akyab gaol was 129·2, and in that of Tavoy 107·8, the high rate in the former being due chiefly to cholera, dysentery, and anæmia, and in the latter to cholera and dysentery. In the convict establishment at the Andamans the death-rate was only 15·75, the most fatal disease being phthisis, the deaths by which amounted to 3·79 per 1000. The troops on duty there also appear to have enjoyed excellent health, the admissions among the Europeans having been only 688 per 1000, with no death, and among the Native troops 826 admissions and 6·52 deaths per 1000. The sanitary sheets received from the gaols, while showing that much has been done to improve some of them, afford abundant evidence of the existence of overcrowding, defective water-supply, imperfect ventilation and drainage, unsatisfactory dietary, and in several of them insufficient clothing.

Although there has been a marked improvement in the registration of births and deaths of the general population in some of the Provinces, it is still so very imperfect as to prevent any reliance being placed upon the recorded results. It would be useless therefore to enter upon any detailed examination of the information on these subjects in the Report, or to constitute any comparison with the results of previous years, when the data were still more inaccurate. The returns show that fevers were by far the most fatal diseases, for of 5,230,756 deaths registered, they were returned as the cause in 3,306,285, or 63 per cent. of the whole. October, November, and December were the months in which the mortality from this cause was highest. Small-pox was very prevalent during the year throughout India, but especially in the North-Western Provinces and Oudh, the Madras Presidency, and British Burmah; the registered deaths by it amounted to 332,904, or 6·7 per cent. of the total mortality. Although every exertion is made to promote vaccination, it is to be regretted that a large proportion of the population remains unprotected. The returns show the numbers vaccinated at the special vaccination establishments and at the dispensaries to have been 5,104,185 in a population estimated at about 184 millions. Cholera was returned as the cause of 287,609 deaths. It was most fatal, in proportion to the population, in Assam, Bengal, Madras Presidency, and British Burmah. In Assam it was very generally prevalent, but was most severe in Nowgong. It broke out in March, reached its maximum in May, and then declined till October, when it was rekindled, and gave rise to many deaths. A very interesting history is given of cholera among the immigrant coolies, who appear to have escaped to a remarkable degree

Digitized by Google

compared with the general population. This is attributed to the improved arrangements at the depôt at Dhubri; to the avoidance of overcrowding on board the steamers; to the increased speed of transport, by which the passage has been reduced from sixteen to a little under five days; and to the improved general sanitary arrangements on board, more especially with regard to cook-houses, latrines, general and hospital accommodation. The Sanitary Commissioner remarks that "of the various explanations which have been offered to account for the diminished prevalence of cholera among them of late years, ... that an improved water-supply is the chief cause cannot be accepted, for Dr. Eteson, the present sanitary commissioner [of Assam] writes:—'The coolies, who alone are provided with protected and filtered water, alone get cholera; other passengers, who always draw water over the side and at landing places where the steamer stops and pollution is most probable, never get it. The crews of all the steamers use unprotected water, and are never attacked.'" In the province of Bengal the disease was widely prevalent, but it was most fatal in Orissa. In the Madras Presidency, Tanjore, Tinnevelly, Trichinopoly, South Arcot, and Madura suffered most severely. The greatest number of deaths occurred in January, the disease then subsiding till April; a second outbreak occurred in July and lasted till October; and it again appeared with considerable violence in December. "The cause of the continued prevalence of cholera in the Tanjore district was most probably owing to the peculiarly contaminated water-supply upon which the people are dependent," and of which some details are given in the Report. The question of the removal of persons from buildings in which cholera has broken out is one of so much importance that we must give the results obtained in India as detailed in the Report. "The effect of movement of affected bodies into other, though near, localities was, as usual, most beneficial. Among British troops cholera appeared in twenty-six communities, and in fifteen of these movements were made into camp, in three to different barracks, and in eight the disease occurred in an isolated form, and no movement was considered necessary. In ten of the fifteen movements into camp no further case occurred after movement. At Allahabad, where nineteen cases occurred in all, only one man was attacked after the affected community moved into camp. Only at Meerut was the result of the movement not so strikingly apparent. In this station the affected men were broken up into five parties, which moved into separate camps. In one party nine cases occurred in three different camps, and in another four cases in two camps, but the three remaining parties escaped without further attack. Amongst Native troops nine of twenty-one affected communities moved into camp, and in only one of them a single case occurred after movement. Amongst prisoners movements were made only at Meerut and Akyab. In the former place only two cases occurred after movement." At Akyab a reference was made to the Inspector-General of Prisons, who directed that "no delay should take place in the matter of removal, but that two-thirds of the prison population should, as soon as possible, be moved into camp. The result justified the expediency of this decision, for no sooner had the removal been commenced, and the gaol population thereby thinned, than the disease began to abate, and speedily became altogether arrested; while of the prisoners who were camped out not one was attacked."

The number of deaths from injuries registered during the year amounted to 76,583, and of these 23,028 were caused by snake bites or by wild beasts.

DR. RICHARDSON'S LECTURES ON ANIMAL OR VITAL MECHANICS.

ON Monday last Dr. B. W. Richardson delivered the first of a series of Cantor Lectures, at the Society of Arts, on "Animal or Vital Mechanics." After a brief introduction, in which he defined as natural or vital mechanics those mechanisms which are produced by nature without the interposition of man or any animal inferior to man, the lecturer placed before his audience a series of photographic and diagrammatic illustrations of numerous natural mechanical parts — the valve, the lever, the camera, the pouch, the screw, the tube, the vesicle, the column, the cord, the pulley, the muscle, and the joint. He then drew a comparison bearing on originality of design between natural and human genius for invention. On this subject there were two views: one, that natural and human inventive skill are independent of each other, though alike in character; the other, that human inventive skill is an imitation or copy from the natural—an idea which even men of scientific attainment had supported.

The lecturer, in treating on these two hypotheses, while admitting that man could not be said to have invented anything that did not exist in nature, and therefore only re-created the created, and while also admitting that in many mechanical works of nature man might find many copies, maintained, nevertheless, that the human faculty for mechanical invention is quite independent, and that man in invention as often recopied from himself without intention, as he did from nature, also without intention. As an artist man is an imitator; as an inventor he is original; the phenomena included in mechanical problems being to him abstractions, like good and evil, space and time. In support of this view, Dr. Richardson urged the following reasons: 1. That if man in his inventions were a mere copyist, he would rank lower in this respect even than insects, which were mechanics, but certainly from no studied imitation from natural objects. 2. That if man had learned all his inventions from the inventions of nature he would have been a naturalist first, and a mechanician afterwards. But, in fact, he is a wretched naturalist; a splendid mechanic. 3. That the attempts of man to copy from nature in mechanical work had been amongst the least successful of his mechanical results, as shown in his attempts from and even before the time of Borelli to make a flying machine. 4. That the skill of man in all his great mechanical results is cumulative, has its origin in smallest beginnings, and progresses step by step onwards by human skill alone. This was illustrated in the development of electricity, from the first experiment of children rubbing pieces of amber up to the telephone and microphone, in the whole of which mighty development, although the phenomena and their causes might have been found in nature, man stood alone as the inventor, without going to Nature for any copy of her designing. 5. That if man had been a direct copyist from Nature, in his mechanical work, he would not have produced such perfect mechanisms as those which he has constructed, since it is one of the most remarkable of facts that many of the most important natural instruments (for example, the eye-ball) are imperfect in details of construction, unfinished, to use a workman's term, and liable to deviation in action. On the whole, the evidence is in favour of the belief that man is endowed with independent powers of invention. This, however, does not take away from the study of Nature as a teacher. Her apparent errors may be guides; she may reveal secrets if she be carefully followed; she may certainly suggest economy of power and of adaptation; and she is ever deserving of consultation as the omnipresent and primitive mechanical organiser and worker.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Wem Rural District.—It is satisfactory to note that according to the report of Dr. R. F. Giles not a single death resulted in 1885 from any one of the specific infectious fevers, and this in a population of 10,565. But it is stated that there were one or two isolated cases of diphtheria, and under these circumstances 2 deaths from "non-spasmodic croup" may be regarded with some slight suspicion. In the general sanitary improvement which is going on, we would note that the town of Wem has received an abundant supply of good water, and the house connexions with this public service are steadily increasing. Action is also being taken in the same direction under the Public Health (Water) Act, and wells which are polluted are being closed. Clive and Shawbury call for similar activity on the part of the authority. Bye-laws are also wanted to regulate the construction of new buildings. It is often felt that because a district is not yet very populous, such regulations are not needed; whereas it is hopeless to prevent the evils of bad

Digitized by Google

building when places ultimately do become populous, in which building has been proceeding without any adequate restrictions. It is in the early stage that bye-laws do the most good. The death-rate for 1885 was 18·45 per 1000; it was much the same in 1884, and for a rural district this can by no means be regarded as being as low as it should be.

Willesden Urban District.—Dr. Branthwaite has the satisfaction of pointing out that in this district, with a population which has increased with immense strides till it has nearly reached 39,000, whereas the death-rate was 21·7 per 1000 at the beginning of the decade, it is only 16·2 at the present time. During the year 1885, small-pox was somewhat prevalent, 31 cases coming under notice. Of these, 13 were treated at home and 18 were removed to the hospital. But something of a permanent character in the way of hospital provision is much needed for this district. In the meantime disinfection is carefully carried out in all houses where infectious diseases have been known to exist. The infantile death-rate of Willesden is a very unsatisfactory feature, for the deaths of children of one year and under are as 17·2 per cent. of the births. Dr. Branthwaite again urges the need of a crèche in South Kilburn, and in the district abutting on Willesden-lane. In his opinion it would lead to the saving of many lives.

Helmsley Rural District.—Routine work continues to be made in this district and to disclose matters calling for continued activity. The risk of well-pollution has been shown to exist in Harome as the result of last year's systematic inspection, but in the case of Helmsley this question has been most satisfactorily dealt with. It is now four years since a case of enteric fever came under Dr. Low's notice in the district, and in this special instance it was regarded as due to the recrudescence of a poison ten years old. The death-rate for the district during 1885 was 16·15 per 1000 living.

Bedford Rural District.—During 1885 the general death-rate of this district on a population of 23,666 was 18·5 per 1000. Scarlatina and diphtheria were the two infectious diseases which most called for notice. As regards the latter, Dr. Prior quotes extracts from a large number of reports of the medical inspectors of the Local Government Board, and he concludes that the main outcome of the investigations referred to has been to show how strong is the evidence in favour of contagion as the great means of propagation of diphtheria, and how weak and unconnected by comparison is the evidence as to other causes. Hence he urges that it is only in the organisation of a proper system of disinfection and of isolation that safety against the diffusion of the disease can be found.

Barnsley Urban District.—Although the death-rate for 1885 was considerably below that for the preceding two years, it reached 21·9 per 1000, and as such was in excess of that for England and Wales. A serious effort has been made by the Town Council to deal systematically with infectious disease, and a fee has been offered to medical practitioners for reporting such cases. This system, to be complete, needs, as Dr. Sadler says, a well-ordered fever hospital; but we think his views as to securing the removal of first attacks are involved in difficulties which are somewhat imaginary. In other districts the same fears have been expressed, but the anticipated drawbacks have tended to disappear when adequate provision has been made. Barnsley has the advantage of an abundant and excellent water-service, of a good system of sewers and sewage disposal, and of a system of refuse removal carried out by the authority's own officials. It is also now required that in all new houses a disconnecting syphon-trap shall be provided, cutting off the chance of the passage of sewer air into house drains, and additional means of sewer flushing are to be provided. Advance in such directions should, before long, lead to a still further reduction in the rate of mortality.

Barnsley Rural District.—In this district the year 1885 was marked by a lower death-rate than any experienced since 1881; but still it cannot be regarded as a really low one, reaching as it did to 17·8 per 1000. Certain cases of enteric fever were associated with foul effluvia from sewers which, by reason of the drought, lacked sufficient flushing. Scarlet fever was also somewhat prevalent; but it is stated that, in the absence of information as to its occurrence, it was not possible to do much to check it. In several parts of the district the sewage arrangements are unsatisfactory, and the river Dearne remains very foul. When faulty sanitary conditions are met with in connexion with disease, they are, according to Dr. Sadler, remedied by removal or otherwise.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5688 births and 3518 deaths were registered during the week ending May 1st. The annual death-rate in these towns, which had been equal to 20·3 and 19·8 in the preceding two weeks, rose again last week to 20·2. During the first four weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 3·7 below the mean rate in the corresponding periods of the ten years 1876–85. The lowest rates in these towns last week were 16·1 in Brighton, 16·3 in Hull, 17·1 in Bradford, and 17·5 in Birkenhead. The rates in the other towns ranged upwards to 26·8 in Blackburn, 27·3 in Preston, 27·9 in Portsmouth, and 29·2 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 367 and 382 in the previous two weeks, declined last week to 364; they included 138 from whooping-cough, 104 from measles, 39 from diarrhœa, 29 from scarlet fever, 28 from diphtheria, 23 from "fever" (principally enteric), and 3 from small-pox. No death from any of these principal zymotic diseases was recorded last week either in Norwich or Halifax; whereas they caused the highest death-rates in Plymouth, Preston, and Portsmouth. The greatest mortality from whooping-cough occurred in Bolton, Cardiff, and Newcastle-upon-Tyne; and measles showed fatal prevalence in Birmingham, Blackburn, Preston, Plymouth, and Portsmouth. The 28 deaths from diphtheria in the twenty-eight towns included 20 in London, 2 in Birmingham, 2 in Liverpool, and 2 in Oldham. Small-pox caused 2 deaths in Bristol, 1 in Liverpool, and not one either in London or in any of the twenty-five other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased in the previous four weeks from 8 to 17, had further increased to 19 on Saturday last; 3 cases were admitted to these hospitals during the week, against 6 in each of the preceding two weeks. The Highgate Small-pox Hospital contained 2 patients on Saturday last, two cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 362 and 319 in the preceding two weeks, further declined last week to 296, and were 94 below the corrected weekly average. The causes of 89, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Blackburn, Derby, and Plymouth. The largest proportions of uncertified deaths were registered in Salford, Sheffield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 20·5 and 20·7 per 1000 in the preceding two weeks, further rose to 23·1 in the week ending May 1st, and exceeded by 2·9 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·4 and 18·5 in Dundee and Leith, to 25·4 in Glasgow and 26·0 in Paisley. The 571 deaths in the eight towns showed a further increase of 60 upon the numbers returned in the previous week, and included 21 which were referred to whooping-cough, 15 to measles, 6 to scarlet fever, 6 to diarrhœa, 2 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one to small-pox; in all, 51 deaths resulted from these principal zymotic diseases, against 34 and 46 in the preceding two weeks. These 51 deaths were equal to an annual rate of 2·1 per 1000, which corresponded with the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 10 and 15 in the previous two weeks, further rose last week to 21, of which 18 occurred in Glasgow. The 15 deaths from measles showed a further increase upon recent weekly numbers, and were all returned in Edinburgh. The 6 fatal cases of scarlet fever, of which 4 occurred in Glasgow, also exceeded the numbers in recent weeks. The 6 deaths attributed to diarrhœa, on the other hand, showed a decline, and were 3 below the number in the corresponding week of last year. Both the deaths from "fever" were returned in Glasgow, and the fatal case of diphtheria in Greenock. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 122

Digitized by Google

and 100 in the previous two weeks, rose again last week to 123, and were within 1 of the number in the corresponding week of last year. The causes of 74, or 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 33·0, 25·0, and 27·3 per 1000 in the preceding three weeks, declined to 24·4 in the week ending May 1st. During the first four weeks of the current quarter the death-rate in the city averaged 27·4 per 1000; the mean rate during the same period did not exceed 19·1 in London and 18·8 in Edinburgh. The 165 deaths in Dublin last week showed a decline of 20 from the number in the previous week, and included 13 which were referred to the principal zymotic diseases, against 16 and 8 in the previous two weeks; 5 resulted from whooping-cough, 2 from scarlet fever, 2 from "fever" (typhus, enteric, or simple), 2 from diarrhœa, 1 from measles, 1 from diphtheria, and not one from small-pox. These 13 deaths were equal to an annual rate of 1·9 per 1000, the rates from the same diseases being 2·4 in London and 3·7 in Edinburgh. The fatal cases of whooping-cough, which had been 11, 5, and 4, in the three preceding weeks, were again 5 last week. The deaths from "fever" showed a decline from recent weekly numbers. Six inquest cases and 4 deaths from violence were registered; and 50, or nearly a third of the deaths, were recorded in public institutions. The deaths of infants were fewer than those returned in any previous week of this year, and those of elderly persons also showed a decline. The causes of 19, or nearly 12 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

FOREIGN GRADUATES AND THE MEDICAL BILL.

To the Editor of THE LANCET.

SIR,—Before the proposed Medical Bill becomes law will you not raise your always liberal voice on behalf of foreign graduates? It is proposed to admit to the Register only foreign degrees which grant the right to practise in their respective countries. This will be a great injustice to all holders of German, Dutch, Swiss, and Brussels degrees, which are quite as honourable as those of America, France, Austria, and Italy, although they do not grant a licence to practise, the State Boards performing this function in Holland, Germany, and Switzerland. The precaution of admitting to the Register only such degrees as are licences to practise may be a useful one for future purposes, but it must be a serious injustice to those who have obtained foreign degrees in the past. To admit an American M.D. to the Register and to refuse a Berlin M.D. will be to bring social obloquy upon the holder of the latter, perhaps even amounting to professional ruin, for the unthinking public will naturally believe that the State recognises the one and stamps the other as inadequate. Surely the least the Government can do is to register all existing foreign degrees properly acquired by already registered practitioners. This is not granting the licence to practise to men holding such degrees, for their British diplomas give them already that privilege; it is merely protecting them from grave injustice, annoyance, and serious professional loss.

I am, Sir, yours truly,

Sheffield, May 4th, 1886. H. J. HARDWICKE, M.D.

TWO CASES OF SPINA BIFIDA.

To the Editor of THE LANCET.

SIR,—In the number of the *Dublin Medical Journal* for March last, I find this remark regarding spina bifida: "As a prognosis is nearly all a surgeon can offer to many spina bifida patients, &c." Perhaps it is too much to expect that by this time, after repeated notices in the journals and the issue of the report of the London Clinical Society, all surgeons ought to be aware that the great majority of such can now be saved both from a fatal prognosis and termination, so far as the malformation itself is concerned. Permit me, then, to mention that since the beginning of this year two cases have been sent to me by other medical men, both of which have been successfully treated. The first of these, a lumbar case aged four weeks, was operated on on Feb. 12th, and required only one injection of the iodo-glycerine fluid. The second, aged three weeks, was injected on March 16th, again on March 30th, and again on April 16th. This is a sacral case. In each the tumour is now shrivelled and flat, and the children are now safe from the risk of death due to the deformity. Further details of these cases may be given along with many others, at an early date.

I am, Sir, yours &c.,

Glasgow, May 3rd, 1886. JAMES MORTON.

SYNCOPE IN ADOLESCENTS.

To the Editor of THE LANCET.

SIR,—Can you afford me a little space to call attention to a clinical fact of some moment, which is not sufficiently known, or, if known, not sufficiently acted upon in the interests of science and for the welfare of our patients.

An adolescent was sent to me with the statement that he had nearly fainted on three different days, but he did not become insensible. He came with the request that I would ascertain the cause of his faintness. Cases of the kind have happened to me under similar circumstances so many times, and their relief at first has been so unsatisfactory and difficult, that my experience may be of value to others, for I have established a fact. I have already incidentally referred to this fact in a former communication, but not so clearly or with such certainty as I wish to do now.

When such cases come under my investigation, I immediately and invariably examine the urine, instead of the heart, and generally find it loaded with albumen. It is therefore highly important that the urine should be examined and the kidneys treated by nitro-glycerine, rather than the heart auscultated and tonics prescribed, "because of the patient's extreme debility and feeble action of his heart, &c." as is usually the case. I have sometimes found, on examination of the heart and pulse, that, besides the marked albuminuria, there exists a heaving heart and somewhat rigid arteries—conditions incidental, I believe, in adolescents, more to the "age of puberty" than to the state of the kidneys. But often, as in a case at present under my care, the heart is really feeble and the pulse totally devoid of the signs of a kidney pulse; and had it not now been my invariable rule to examine the urine in preference to the heart, I should doubtless have prescribed a tonic regimen, to the detriment of my patient. The treatment for the two conditions is so opposite that I do not hesitate thus to call special attention to it: a feeble heart and pulse being relieved by tonics, good food, and stimulants; while congested kidneys are alone cured by a hot bath, nitro-glycerine, an aperient, and milk only as a diet. With such treatment this syncope of adolescents is usually cured in a few hours, and with daily prudence for some time there will be no return of syncope or albumen, and the patient will express himself as vigorous again.

I am, Sir, yours obediently,

CLEMENT DUKES, M.D. Lond., &c.,
Rugby. Physician to Rugby School.

THE USE OF COCAINE IN SURGERY.

To the Editor of THE LANCET.

SIR,—If you are not tired of publishing notes of the various merits of cocaine, the following may perhaps be of interest.

I recently had occasion to stitch up a ruptured perineum some weeks after labour. The first step was the insertion between the edges of the tear of a pledget of cotton-wool soaked in a 20 per cent. solution of cocaine. This was at 12.30 P.M. I then proceeded to get the operating table in order and arrange my instruments, which took twenty minutes. At 12.58 P.M. the patient took up her position in the lithotomy attitude, and I was able to inject two minims of the same solution into either side of the rent painlessly. Leaving that to take effect, I occupied myself with other matters, such as threading needles, &c. At 1 P.M. I was able to pare the edges and insert deep sutures without any pain. The operation took

Digitized by Google

some time owing to the irregularity of the rent, and at about 1.25 I had to inject one drop here and there. This enabled me to finish the operation, during the whole of which the patient felt no pain. She conversed freely throughout, and I had the great advantage of her intelligent obedience, instead of the usual restlessness of a patient under chloroform. Thus, in time cocaine is economical, as while it is taking effect the surgeon can be attending to matters which, with chloroform or ether, must be seen to beforehand; and there is also a saving in money, as no assistant is required, and the actual cost will bear comparison with that of chloroform. This operation cost me twenty minims of a 20 per cent. solution, or four grains, which, at 1¾*d.* a grain (the present price), comes to 7*d.*

I have also performed circumcision on a young man at a cost of five minims, or one grain, = 1¾*d.* The operation, including the arrangement of the patient and instruments, occupied twenty minutes only. Of course, in this case the original injection of the cocaine—one drop of a 20 per cent. solution into four separate parts of the prepuce—was painful, but if a very fine needle is used the discomfort is trivial.

Another advantage of cocaine (though a decided disadvantage sometimes) is that, whereas œdema coming on after an operation often strains the stitches more than can well be calculated upon or allowed for at the time, the injection of the drug rapidly induces this swelling; and the tension put upon the sutures in tying them will be found suitable to the subsequent condition of the parts.

I look upon cocaine as a special boon to the general practitioner who has to work single-handed or with inefficient assistance.

I am, Sir, yours faithfully,

Tottenham, May 3rd, 1886. A. OGIER WARD, M.B. &c.

"THE PRIZE SYSTEM."

To the Editor of THE LANCET.

SIR,—Your correspondent, "F.R.C.S.," sends you an interesting extract showing Sir Benjamin Brodie's opinion of giving prizes to medical students. In his autobiography he is still more emphatic, and the opinion of a surgeon so successful in the highest sense of the term must carry weight. He says: "I had leisure to make my own observations, to think and reflect. Nor was this style of education peculiar to myself. I remember when Mr. Abernethy complained that Lawrence would not attend lectures. My friends and contemporaries, Jeffreys and Lawrence, took the same course; and so it had been with Nicolson, who was some years in advance of us. I can easily conceive that, if I had been compelled to sit on the benches of a theatre four or five hours daily, or tempted to compete for prizes as students are, and to get crammed for various examinations, my position in life afterwards would have been very different from what it has been in reality."

I am, Sir, yours &c.,

Wimpole-street, May 2nd, 1886. G. BUCKSTON BROWNE.

TRAINED NURSES IN INFECTIOUS CASES.

To the Editor of THE LANCET.

SIR,—The now numerous institutions for the supply of trained private nurses meet a great public want, and I believe that upon the whole they are well managed and deserve the success which they have attained. Having recently had occasion to make inquiries as to the precautions observed by some of them with regard to infectious cases, I find that there is a considerable difference in their practice in this respect. The rules of the Nottingham and Notts Nursing Association—to quote an example—require that a nurse upon leaving an infectious case shall not only undergo a thorough disinfection of person and clothing, but shall remain in quarantine for two weeks before taking charge of another patient. This is as it should be; and similar rules are enforced at Sheffield, and no doubt at many, if not most, other centres. Recent experiments tend to make us very sceptical as to the entire trustworthiness of many of the ordinary processes of disinfection, and in view of the possibility of a nurse herself acquiring the disease or conveying infection in spite of disinfectants, the period of quarantine must be regarded as a wise and necessary precaution. It is, therefore, with some surprise that I find it ignored by at least one institution, nurses being sent, after ordinary disinfection, to new patients immediately after returning from infectious cases.

In one instance which came to my knowledge recently, a nurse returned from a fatal case of diphtheria and was next day sent to take charge of a case at a distance. This second case also subsequently proved to be diphtheria, and ended fatally. The nurse, being questioned as to the nature of the illness of her former patient, asserted that it was "croup." The diagnosis of diphtheria was made within a few hours after the arrival of the nurse, so that it seems highly improbable that the infection was brought by her, but the possibility of this led to inquiries, and thus to the discovery of the facts already stated. How far other nursing institutions share this custom I cannot say, but such laxity is a source of danger, and is unworthy of an institution which appears to enjoy the confidence of the medical profession and the public. Most practitioners would, I think, hesitate knowingly to expose their patients to the risk of being attended by a nurse fresh from an infectious case, especially where they have no means of judging of the efficacy of the safeguards adopted. In the absence of any provision for obtaining the consent of the responsible medical attendant to such a course, it is incumbent upon the managers of nursing institutions to recognise their full responsibility and to take all reasonable measures of precaution.

I am, Sir, yours faithfully,

B. A. WHITELEGGE, M.D., B.Sc.,

May 3rd, 1886. Medical Officer of Health, Nottingham.

"ON THE RATIONAL TREATMENT OF HYDROPHOBIA."

To the Editor of THE LANCET.

SIR,—The medical profession will be under great obligation to Mr. Richards for the timely warning he has given of the dangerous or fatal dose of the snake poison which was advocated in my paper on the Rational Method of Treatment of Hydrophobia in your issue of January last. Unfortunately for my critic, he has set up a phantom to enjoy the self-satisfaction of seeing it knocked down by his missiles, for he ascribes to me a dose which I am innocent of. In my paper referred to above I suggested one drop of the poison, which my critic has transformed into one grain, which is equivalent to three minims or five or six drops of the liquid poison. Thus, having magnified my dose five times, like the true valiant knight of the fable he has hurled down his weapons of assault for my demolition.

My personal thanks are due to him also for the gratuitous offer of enlightening my knowledge on woorara having been used in hydrophobia, but I would not injure his self-esteem by assuring him that I had the fullest consciousness of the fact. Then, in a spirit of *nonchalance* as it were, he kindly passed over "the crude and incorrect physiological action of the poison," as enunciated in my paper, to attack the most important and vulnerable portion he found in it—the dose. Like other critics of his class, he evidently rejoices in finding fault with the tail of a horse to the exclusion of its body and limbs. But perhaps Mr. Richards, who is superintendent of coolies in Goalunda, is not aware of the fact that in diseased states of the system there is a toleration for medicines with opposite physiological actions. Thus, in delirium tremens and diarrhœa a quantity of opium will be admissible which will be poison in a healthy state. Taking, therefore, my recommendation of dose as one drop and in a diseased condition of the body, I do not think I have overshot the mark and suggested to the profession a fatal remedy, with which I have been charged by him.

I am, Sir, yours truly,

Burdwan, April 13th, 1886. G. C. ROY, M.D., F.R.C.S.

LIVERPOOL.

(From our own Correspondent.)

THE SCHOOL OF MEDICINE.

THE Summer Session of the Medical Faculty of the Liverpool University College commenced on the 3rd inst. The staff of lecturers has been augmented by the recent election of Dr. Edward William Hope, assistant medical officer of health to the City and Port of Liverpool, as lecturer on

Digitized by Google

Hygiene. Dr. Hope possesses an eminently practical knowledge of the subject, which his appointment gives him daily opportunities of increasing. Mr. Paul, the lecturer on Medical Jurisprudence, has been called upon to make necropsies and to give expert evidence in several recent important trials, and it is hoped that this course of lectures will be made as practically interesting and instructive as similar courses have been in Edinburgh, Aberdeen, and elsewhere. The anatomical rooms are well supplied with subjects, and this class is fairly well attended. The entries of new names is equal to that of former years, which is very satisfactory, as the depressing influences so often alluded to at the present time must have an effect on medical schools.

DRUNK OR DYING.

Another case has been added to the many in which severe injuries to the head have in their symptoms so closely resembled those of alcoholism as to be mistaken for them. An inquest was held on Saturday on the body of a man, forty-seven years of age, who was found at the bottom of some cellar steps on the evening of the 20th ult. When lifted up he was unable to speak, was very sick, and smelt strongly of drink, but showed no signs of any injury whatever. He was removed by the police as drunk and incapable to the nearest bridewell, where he was seen by the surgeon, who certified that he was fit to remain there. Later on he was transferred to the main bridewell, the surgeon of which also saw him and recommended his removal to the workhouse hospital. He was, however, taken before the magistrates, who permitted his removal home by his friends on condition that they would take him home in a cab and procure him medical attendance. He lingered until the 29th, when he died; and on a post-mortem examination being made by Dr. Powell, it was found that the skull was fractured, but that there was no external sign of this whatever. A witness stated before the coroner that he had seen the deceased a short time before he was discovered, and that he was then quite sober. The jury found that the deceased died from fracture of the skull, though how caused there was no evidence to show, and exonerated the police from all blame.

'WATCH AND WATCH."

The recent loss of the *Oregon*, though happily unattended by loss of life so far as she was concerned, was accompanied by the total loss, with all the crew, of the vessel with which she collided. The present time seems opportune for again calling attention to the dangers which must exist so long as the "watch and watch" system continues. The meaning of the latter is that from the time of leaving one port until arrival at another the officers can never have more than four hours' continuous sleep. The natural consequence of such an arrangement must be that they arrive on the "bridge" in a physical condition the very reverse of that wide-awake state in which they ought to be if lights are to be quickly sighted and collisions avoided. The remedy is a very simple one, and has been for a long time adopted in the engine-room generally, and on the bridge in some steamers. It is by having three watches instead of two, and thus enabling the officers and crew to have four hours on duty with eight hours off. By this means sufficient sleep is procured and greater vigilance guaranteed. The continuance of the "watch and watch" duty cannot be justified, and entails an amount of physical strain which might almost be termed cruelty.

THE APPROACHING ROYAL VISIT.

In view of Her Majesty's visit to this city, which now draws near, the Committee appointed by the City Council to make arrangements for the reception of Her Majesty have wisely issued a notice warning all owners and occupiers of property along the line of route to carefully inspect and secure all projecting balconies and all projections upon which people are likely to congregate. The city engineer is authorised to give all reasonable assistance and advice, and thus by this precaution many accidents may be averted. At the last meeting of the Select Vestry it was resolved to give the inmates of the workhouse a substantial dinner of roast beef and potatoes on Wednesday next in honour of the Queen's visit; and also that they should have some pleasant entertainment in the evening of that day.

ELECTION OF A LANCASHIRE CORONER.

Dr. Joseph Bray Gilbertson has been duly elected coroner for the Hundreds of Amounderness and Leyland. This gentleman, who has acted as deputy-coroner to his late brother, graduated M.D. at Aberdeen in 1859, became a member of the Royal College of Physicians of Edinburgh in 1878, having taken the qualifications M.R.C.S. and L.S.A. Lond. in 1849 and 1850. He is a Justice of the Peace for Preston, and Physician to the Preston and County of Lancashire Infirmary.

Liverpool, May 4th.

MANCHESTER.

(From our own Correspondent.)

THE VICTORIA UNIVERSITY.

THIS University may, ere long, expect to have its affiliated colleges increased by the addition of the Yorkshire College at Leeds. On the 14th ult. a special meeting of the Board of Governors of that College was held, for the purpose of considering the recommendation of the Council: "That steps should now be taken to secure the admission of the College to the Victoria University." It was stated that the capital of the College had increased during the past ten years from £13,276 to £146,000. A resolution was passed: "That the Council be authorised to take steps to secure the admission of the College to the University so soon as the capital funds of the College shall have been increased to such an extent as will provide a sufficient income to cover the increased expenditure to be entailed upon the College by the affiliation." It was estimated that the increased expenditure will amount to only £250 a year, so that this sum should soon be secured. Old Owens College students will regret to hear of the death of one of the oldest of its teachers, Professor Theodores. His name was associated with the College in its earlier and humbler days, long before the handsome pile of buildings had arisen in Oxford-road. Few men in this country had a more intimate knowledge of Oriental languages, and it is stated that he was acquainted with upwards of forty modern languages.

THE MEDICO-ETHICAL SOCIETY.

Among the objects for which this Society ostensibly exists is "the promotion of good-fellowship among the members of the profession," and it has during the past session very successfully prosecuted this part of its *raison d'être*. Last week it held the second social meeting, at which business was soon disposed of to make room for more convivial matters. Judging from the attendance, these social nights are appreciated by the members.

MEDICAL OFFICERS OF HEALTH.

Amongst the many topics brought forward by the Manchester and Salford Sanitary Association for consideration and attention has lately been that of the *locus standi* of medical officers of health, and the committee have forwarded a petition to the Local Government Board pointing out the disabilities which those officials at present labour under, and asking the Board to take steps on certain lines indicated by the Association to secure the appointment of properly qualified men for this work throughout the country, and to render their tenure of office more secure.

THE ROYAL INFIRMARY.

The Board of the Royal Infirmary have sanctioned, on the recommendation of the Medical Committee, the formation of a new appointment—viz., a chloroformist. Hitherto these duties have been undertaken by the assistant medical officers, or, in their absence, by one or other of the house-surgeons. The new post is to be a non-resident one, and have attached to it a stipend of £50 per annum.

PIT-BROW WOMEN.

Much local interest has been caused by the proposals in Parliament to make illegal the employment of women on the pit-brow of coal mines, and much correspondence, both for and against, has taken place in the local papers on the subject. Judging from what one sees and hears, the desire of the women themselves is strongly in favour of being allowed to continue at the work, and although, to a stranger passing, for instance, on the railway through the Wigan district, the first sight of these women attired in semi-masculine costume is likely to produce a strong feeling against such an employment, yet a closer acquaintance with the workers and inquiries into their living and habits show that it com-

Digitized by Google

pares favourably with that of female mill hands and factory operatives, while for health and physical vigour the advantage is undoubtedly on the side of the colliery women.

HOSPITAL SATURDAY AND SUNDAY.

The total sums received this year from the hospital collections amount to £7484, £4605 11*s.* being from the Hospital Sunday Fund, and £2878 9*s.* from the Saturday Fund. Considering the large number of unemployed during the past winter, and the exceptional demands upon the generosity of the charitable part of the community, it is satisfactory that the amount has reached so much.

During the past few weeks measles has become very prevalent in some parts of the district and the adjoining township of Withington, and the schools have, by order of the sanitary authority, been closed until the middle of this month.

Manchester, May 3rd.

EDINBURGH.

(From our own Correspondent.)

OPENING OF THE SUMMER SESSION.

THE summer session in the Edinburgh Medical School was opened at the beginning of this week, and it is satisfactory to learn that the number of students flocking to the city is still constantly on the increase. The number of courses of instruction, both practical and systematic, is also considerably augmented. Amongst these additions may be noted Dr. Berry Hart's course on Midwifery and Diseases of Women, at the Royal College of Surgeons; Dr. Caird's course of Operative and Practical Surgery; and Dr. Barbour's course on Obstetrics and Gynæcology. These, and the large series of other courses to which they are additions, form the basis of the far-spreading system of extra-mural education which is so largely developed in Edinburgh, and which, by its active competition with the corresponding curricula within the University, have done much to maintain the efficiency of university teaching. These valuable additions to the strength of the extra-academical school must, therefore, be looked upon as bearing most favourably and directly upon the maintenance of a high standard in our medical education.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE banquet given last week by the President, Sir Charles Cameron, was a magnificent success, and 186 guests sat down to dinner, which was sumptuously served. The toasts were numerous, and included "The Municipality," proposed by the Vice-President of the College, Mr. William Stokes, and "The Medical Licensing Bodies," by Mr. Macnamara. The latter toast was responded to by Sir George Paget, K.C.B., the Provost of Trinity College, the President of the College of Physicians, and the Governor of the Apothecaries' Hall. The *ménu* cards were very elaborate, and, besides bearing the name of each individual guest, had three engravings—viz., the Pole Gate Guildhall of Dublin Surgeons, sixteenth century; the Royal College of Surgeons, Ireland, in 1810 and 1886. The statue of Mr. William Dease erected by his grandson, Mr. O'Reilly Dease, D.L., which was unveiled last week, is placed, as has been previously mentioned, in the entrance hall of the College. It bears the following inscription:—"William Dease, one of the Founders of this College, and afterwards its President, and first Professor of Surgery. Obiit 1798. Sir Charles A. Cameron, Knt., President; William Stokes, Vice-President; William Colles, Secretary. April, 1886."

CARIES OF THE SPINAL COLUMN.

Mr. William A. Elliott, of this city, has had more experience in treating deformities to which the human frame is liable than almost any other surgeon practising in Dublin, and therefore reference to a monograph lately published by him on caries of the spine may be considered as worth mentioning. As Mr. Elliott truly remarks, in no department of surgery has there existed more discrepancy of opinion than respecting the general treatment of spinal caries, but the greatest preponderance of opinion is in favour of the adoption of some form of local counter-irritation, and the use of some mechanical appliance to afford support to the diseased spine. The local treatment Mr. Elliot recommends is the application of small blisters applied at each side of the spinous process of the affected part, and left on only to allow the skin to be reddened, and not intended to produce vesication. As regards abscesses connected with the disease, he adopts the method for opening them recommended by Abernethy—that is, a valvular incision. He considers that mechanical support should be used early, and he points out that the most difficult portion of the spinal column to retain motionless is that which extends from the first cervical down to about the sixth dorsal vertebra. The mechanical appliance he adopts in caries of the cervical vertebræ is made of thick leather, known as "tanned," but not curried, which, before using, is soaked in warm water, so as to make it pliable. The leather is then cut so as to pass well over the shoulders, chest, and back. It may then be made to pass upwards and round the neck, and sufficiently high to allow the occiput and lower jaw to rest upon it. A bandage is then applied over the entire surface of the leather, on the removal of which an accurate mould will be made of the parts; and, when perfectly dry, the instrument should be lined with thick chamois leather, with straps and buckles to keep it firmly on the patient. When the disease is situated in the upper dorsal vertebræ, the appliance can be made available by attaching to its lower and back part a piece of the same description of leather sufficiently long to pass down to the lower part of the dorsal vertebræ, round the body, and made to lace in front; while the corset for cases of caries of the dorsal or lumbar region should nearly close in front, and should extend from the axillæ downwards over each crista ilii.

CORK HOSPITAL FOR WOMEN AND CHILDREN.

The new building was opened last August, and the number of applicants for admission since the new hospital has got into working order shows that the extra accommodation has been taken advantage of by the public. During the past year 203 intern patients were treated in the wards, and the average cost of each bed came to £39 5*s.* Towards the expenses of the building the necessary amount has been subscribed, with the exception of about £400, while Mr. Crawford has generously assisted the board by a donation of £440 towards the furnishing of the new institution.

THE RIVER LIFFEY.

A member of the Dublin Corporation has given notice that at the next meeting he will move for a committee of twenty members to report to the Council on the practicability of carrying out a scheme of intercepting sewers, at a cost not exceeding £120,000.

Dublin, May 4th.

BELFAST.

(From our own Correspondent.)

JOHN WOODS BECK, M.D.

IT is with regret I have to announce the death of Dr. Beck, which took place at his residence in Belfast on May 2nd. Dr. Beck studied at the University of Glasgow, where he graduated in 1839, and since that time he has been engaged in practice in Belfast, so that he was one of our oldest medical practitioners. Prior to the establishment of the Irish dispensaries in 1852 he was one of the Poor-law officers, and during the severe epidemics of cholera which visited this town he took an active part. Although very well known in local circles, Dr. Beck came little before the public. He was most popular among the poor and enjoyed a good reputation as an obstetrician, and was much consulted by them in reference to children's ailments. Dr. Beck had been unwell for the past three months, and died in his sixty-seventh year. One of his sons, Dr. F. E. Beck, is engaged in active practice in Belfast.

THE RIVER LAGAN NUISANCE.

A very influential deputation appeared before our Town Council on Saturday in reference to the Lagan nuisance. This deputation came, first, to express dissatisfaction that no direct provision had been made in the Main Drainage

Digitized by Google

Bill for the purpose of cleansing the river; secondly, to urge the Town Council to carry out immediately the connection of the Ballynafeigh sewer with that of the Lagan village in accordance with the original plans; and, next, to protest against Clause 75 of the Main Drainage Bill, which, it was contended, throws upon the borough at large the expense of completing certain sewers, the cost of which should fall on the owners of property in the immediate locality. One of the deputation referred to the triumphant return of Dr. Graham, Alderman in Cromac ward, against the formidable opposition of a gentleman who had been Mayor of Belfast, as one of the proofs of feeling which existed on this subject among the inhabitants. The deputation having been heard, it was proposed to refer their views to a committee, when Alderman Graham, who was returned on the Public Health platform, moved an amendment that orders be given for the immediate completion of Ballynafeigh and Lagan district sewers, and that the executive sanitary inspector be instructed to examine into and report on the sanitary state of the river Lagan, also as to the best means of affording immediate relief, and the probable cost of so doing. Dr. Graham pointed out that, even if the new works should be completed in seven years, the greater part of the sewage now discharged into the river would still remain, and that vast quantity of filthy sludge and fæcal matter would be a source of disease for twenty years after. In the debate which followed, one of the speakers advocated a plan of removing the nuisance—viz., to narrow the stream and put on two sets of floodgates to keep the water always at high level, and then, when the gates were opened to admit lighters, the scour would be so great as to carry the offensive matter out to sea. Dr. Graham's amendment was defeated by twenty-five votes to six, and the matter now stands referred to the Improvement Law and Public Health Committees. It is to be hoped that our municipal fathers will give some real attention to this intolerable nuisance, which is yearly getting worse, and which is certainly a disgrace to a town of such size and prosperity as Belfast.

HEALTH OF BELFAST.

Dr. Browne, officer of health, states that since his last monthly report the medical officers of health of the several dispensary districts have returned only four cases of zymotic diseases as having occurred among the poor—viz., two of typhus and two of scarlet fever. The total births registered in the four weeks ending the 25th ult. amounted to 541, the total deaths to 450, showing a natural increase in our population of 91 individuals. There were 77 deaths among infants under one year of age, and 78 of persons at or above sixty years of age. The average death-rate from all causes in the month was 26·1, from lung disease 11·9, and from zymotic diseases 1·8, in a population estimated at 221,000. The death-rate in children under one year of age was 4·5, and amongst persons at and above sixty years 4·6. The deaths from zymotic diseases show a death-rate of 1·8, a very low figure.

THE VACANT CORONERSHIP FOR SOUTH ANTRIM.

Dr. M'Ninch (Ballyclare), Dr. Spearing, Dr. Taggart, and Dr. J. J. Adams (Antrim) are candidates for the vacancy caused by the death of Surgeon-Major Taggart. Their election addresses have appeared, and a very active canvass of the voters is being made.

PARIS.

(From our own Correspondent.)

THE ASSOCIATION GÉNÉRALE DES MÉDECINS DE FRANCE.

THE twenty-seventh annual meeting of the Association Générale des Médecins de France, which took place on Sunday in the large ampitheatre of the Assistance Publique, was unusually well attended, not only by the Paris members of the Association, but also by a great number from the provinces. There were two circumstances that probably formed the attraction of the meeting: the election of a President and the promotion as Commander of the Legion of Honour of M. Henri Roger, whose tenure of office as President of the Association had just expired. M. Roger has, however, been almost unanimously re-elected for another period of five years, and as soon as he was proclaimed he returned to the seat he had just vacated. He had on his right Baron Larrey, and on his left the celebrated Ricord, who, notwithstanding that he is in his eighty-sixth year, was looking hale and vigorous." He certainly has not changed much in features during the last twenty years; and were it not for a slight stoop and a little slowness in his gait, he would never be credited with his weight of years. He has scarcely a wrinkle on his face, and his hair is still luxuriant, being of an auburn colour, and almost entirely unmixed with white. In reading his report for the past year, Dr. Foville, the General Secretary of the Association, took the opportunity of congratulating M. Roger, not only on his re-election as President, but also on his promotion to Commander of the Legion of Honour. In referring to this latter circumstance, he drew the attention of his hearers to the fact that any Government, of whatsoever character, would in honouring such a man honour itself. The General Secretary, as well as two or three other speakers who followed him, also attested to the prosperous condition of the Association in every respect. Its great utility has been pointed out, and as it possesses a capital amounting to a million and a half of francs, or £60,000, the Association will now be enabled to extend succour to a greater number of applicants (who are, unfortunately, on the increase), which is the principal object of the Association.

M. PASTEUR.

I have had an opportunity of revisiting M. Pasteur's laboratory in the Rue d'Ulm, under the following circumstances:—A young lady, a daughter of Mr. Morisini, the well-known banker of New York who was said to have been bitten by a mad dog, was brought to Paris to undergo M. Pasteur's anti-rabic treatment. The young lady was accompanied by her parents and by Dr. Bulkley, the celebrated dermatologist of New York, who asked me to introduce him to M. Pasteur. This I gladly consented to do, and on Monday morning, the 3rd inst., the day after their arrival in Paris, the young lady was inoculated with the anti-rabic fluid. But before the operation was performed M. Pasteur, as is his wont, inquired particularly into the circumstances of the case. Dr. Bulkley furnished the necessary information and produced a certificate from a well-known veterinary surgeon testifying to the dog having been really affected with rabies. The young lady was bitten on April 14th on the space between the root of the nose and the inner angle of the right eye, which was soon after freely cauterised with the nitrate of silver by Dr. Bulkley. Nineteen days had therefore elapsed between the accident and the inoculation. During my visit at the laboratory it struck me that the hydrophobia scare had not lessened, for the place was crowded with applicants from all parts of the world. M. Pasteur is as zealous as ever, and I learn that the Emperor of Brazil has conferred on the eminent biologist the Order of the Rose.

Dr. Ranvier has been elected Member of the Academy of Medicine, and M. Chauveau Member of the Academy of Sciences in the Veterinary Section, in the room of M. Bouley, deceased.

Paris, May 5th.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Samuel Fuller, to be Deputy Surgeon-General, vice J. O'Nial, C.B., promoted; Brigade Surgeon Thomas Norton Hoysted, to be Deputy Surgeon-General, vice W. Skeen, M.D., deceased; Surgeon-Major John James Chappell, M.D., to be Brigade Surgeon, vice S. Fuller; Surgeon-Major William Cherry, to be Brigade Surgeon, vice T. N. Hoysted.

ADMIRALTY.—The following notice is substituted for that which appeared in our columns on the 17th ult.:—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Connolly, M.D., has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointment has been made:—Thomas S. Morley, to be Surgeon and Agent for the districts of Burton-on-Humber, New Holland, and Ferriby.

ROYAL NAVAL ARTILLERY VOLUNTEERS (BRISTOL BRIGADE).—William Edwd. Pountney, M.D., to be Surgeon.

THE Leicester Board of Guardians on the 4th inst. passed a resolution, by twenty-six to eight, forbidding prosecutions under the Vaccination Acts.

Digitized by Google

ROYAL COLLEGE OF PHYSICIANS.

AT the ordinary Comitia of Fellows of the College on the 6th inst., Sir W. Jenner, Bart., President in the chair, the following gentlemen were elected to the Fellowship:—Edward Seaton, M.D. Lond.; Heinrich Port, M.D. Erlangen; Edwin Rickards, M.B. Oxon.; John Abercrombie, jun., M.D. Camb.; James Kingston Fowler, M.D. Camb.; Nestor Isidore Charles Tirard, M.D. Lond.; Donald McAlister, M.D. Camb.; George Gulliver, M.B. Oxon. Dr. Dyce Duckworth, Treasurer of the College, was elected Representative of the College in the General Medical Council, in the room of Sir H. Pitman, resigned.

The Murchison Scholarship was awarded to Mr. John Stuart Hutton, of St. Thomas's Hospital. There were eleven candidates, all of high order of merit. The President, in making the award, referred to the character and work of Dr. Murchison, in whose memory the scholarship was founded.

A communication from the Association of Persons holding Sanitary Science Certificates, requesting the aid of the College in procuring for the holders of such certificates a right to registration, was referred to the Medical Bill Committee. A communication was also received through the Foreign Office on behalf of a proposed International Congress in Hydrology and Climatology to be held at Biarritz in October.

The Medical Bill Committee presented an *ad interim* report, which was adopted. It pointed out that the 3rd clause of the Bill would deprive the College of its privilege of granting licences to practise medicine, surgery, and midwifery, and recommended that a deputation should be sent to Sir Lyon Playfair on the subject, and that Sir R. Webster, M.P., Sir H. Holland, M.P., and Dr. Farquharson, M.P., be requested to watch the progress of the Bill.

The proposals of Dr. West that standing committees should be appointed upon (1) educational matters, (2) matters of professional interest, and (3) matters of public interest, were then discussed; and the report of the Council, which was unfavourable to the scheme, was carried by a large majority.

MEDICAL NOTES IN PARLIAMENT.

Medical Acts Amendment Bill,

IN the House of Commons, on the 3rd inst., in moving the second reading of the Medical Acts Amendment Bill, Sir Lyon Playfair said that since 1870 twenty-one or twenty-two Bills upon the same subject had been brought before the House, but owing to the interests affected, and the jealousies of the different medical bodies, those Bills had all failed. He trusted that the present Bill would settle all the difficulties which had so much disturbed the minds of medical men. There were 16,000 medical men throughout the country. Those men went upon the Register and practised medicine through the means of nineteen bodies. Those bodies were partly universities throughout the kingdom, but they were also licensing corporations, such as the College of Surgeons, the College of Physicians, and the Apothecaries' Company. At present, through any of those bodies, medical men might go upon the Register and practise, and receive fifty or sixty titles to practise, and a bewildered public had no idea whether those titles signified an efficient qualification for a medical man. A surgeon might attend medical cases, such as measles and scarlatina, without having passed a medical examination at all; or a medical man might go and cut off a leg without having passed an examination in surgery. A surgeon might practise medicine, and a physician surgery, without knowing anything about midwifery. That was the state of the law, and it was a very bad state. In England the College of Physicians and the College of Surgeons had combined to have one qualifying examination both in medicine and surgery. That was a voluntary and not a statutory combination. In Scotland the same thing had been done; but in Ireland no combination had yet been effected. The leading principle of the Bill was this—no man in future could get upon the profession without a qualifying examination, which meant that a man must pass a thorough examination in medicine, surgery, and midwifery. The universities might, under this Bill, continue to give the qualifications they now bestowed, but the corporations, if they desired to form a qualifying combination, must combine together, so that the College of Surgeons would unite with the College of Physicians, and both give a qualifying examination over the area necessary for the medical profession. The Bill provided that the Medical Council, which was established in 1858, should have the power of adding a sufficient number of examiners in order that they might get a qualifying examination. By this Bill four popular representatives, two from England and one each from Scotland and Ireland, would be elected to the Council by the medical men themselves. The Medical Council would also have power to send inspectors to see that the examinations were sufficient and efficient, and if they found a body not doing its duty, they might, with the consent of the Privy Council, disqualify that body from giving qualifications. The Bill further provided that properly qualified colonial medical practitioners should be received on the Register, provided that there was reciprocity between ourselves and the colonies in this matter. He believed that the Bill would settle a long and vexed question, and would enable only those to get upon the Register who were qualified by education and examination in the three great branches of the medical profession.—Sir H. Holland expressed his regret that it had not been thought opportune to make a consolidation of the Acts.—Dr. Foster said that he supported the second reading on behalf of a large body of medical practitioners, but they did not support it so cordially as they would a larger measure of medical reform. For twenty-eight years they had been struggling to amend the Act of 1858; they had seen the failure of many attempts at legislation; and now they were naturally disappointed that the Bill was not wider in its provisions and more sweeping in its reform. For twenty-eight years the profession had been taxed to keep up a Council which had thwarted their desires, and now the representation that was given was inadequate. The three parts of the United Kingdom were disproportionately represented in the proposed Council, having regard to the medical population of each part. England, with 16,978 practitioners, was to have only two directly elected representatives; Scotland, with 2372, one representative; and Ireland, with 2501, one representative. England ought to have four and the other countries one each. Altogether, including the corporate bodies, as the Bill stood, Ireland would have seven and Scotland eight representatives out of the twenty-eight.—Dr. Farquharson said that he was of opinion that many of the charges which had been brought against the medical corporations, particularly in Scotland, had not been borne out by the facts. It was certainly an anomalous state of things that nineteen examining bodies should be allowed to compete for the right of conferring a qualification on a practitioner. He concurred generally with the remarks of the previous speaker as to the constitution of the General Medical Council. It had been a great grievance on the part of the medical profession that they had had no direct representation on this body. The Council might be cut down one-half with great advantage.—Sir H. Roscoe supported the second reading of the Bill. In one respect it had a distinct advantage over its predecessors. It did not suggest any cut-and-dried examination, but by the influence of the Medical Council it endeavoured to bring all the various medical examining boards into harmony, and to raise and establish a standard in each. He was pleased to find that the universities were to have a fair share of representation. It was important to bear in mind that it was teaching and not examination which created the medical man, and every advantage ought to be given to the university in which these subjects were taught according to the highest modern standpoint. While he was sure that the Bill would be received with great satisfaction, he felt that the medical profession was not so fully represented as it deserved to be.—Mr. Addison pointed out that under the present law any man could practise both medicine and surgery if he did not assume a qualification. The Bill before the House did not propose to deal with such a person, and therefore he considered it was defective.—Mr. Bryce ex-

Digitized by Google

pressed his belief that the Bill would receive the support of every member of the Commission which inquired into the subject a short time since. With regard to the remarks of Mr. Addison, he pointed out that the Bill did not propose to deal with such a case as that to which he had referred. The Government had not thought it wise to load the measure with such a controversial provision.—The Bill was then read a second time.

The Vaccination Laws.

On the 4th inst., Mr. Robinson asked the Secretary of State for the Home Department whether it was true that Charles Hawyard, mechanic, of Ashford, Kent, had been summoned before the magistrates of that town fourteen times within twelve months, and fined seven times by them for neglect to vaccinate one and the same child; whether he would remit the seventh penalty of 20*s.* and 12*s.* costs imposed on April 13th; and whether he would lay upon the table of the House a letter, dated March 18th last, addressed to the Lord Chancellor by Mr. Baker, who was counsel in the case on the 13th summons, calling attention to the illegality of the proceedings. Mr. Childers, in reply, stated that, as far as any remission of penalty was concerned, he saw no reason to recommend the indulgence of the Crown in favour of any person who persistently refuses to comply with the law. He would ask the Lord Chancellor whether he had any objection to lay the letter referred to upon the table, but doubted whether his doing so would be in accordance with custom.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on April 29th:

Blacker, Edward Spencer, Brighton.
East, Charles Harry, L.S.A., Tittering.
Hains, William Robert Hall, L.R.C.P.I., Plymouth.
Hall, William George, L.S.A., Swindon.
Hubbard, Daniel Lovett, L.S.A., The Grove, Clapham.
Jones, George Burnett Mander, L.R.C.P. Lond., Sydney, N.S.W.
Leech, Arthur Herbert, L.S.A., Woolpit, Suffolk.
Morgan, James Campbell, L.R.C.P. Lond., Blackheath.
Noyes, Alexander Wellesley Finch, L.R.C.P. Lond., Melbourne.
Paine, William Henry, L.S.A., Lewisham.
Paul, George W. Frederic, L.R.C.P. Lond., Ladbroke-grove-road.
Pearson, George Kenneth, L.R.C.P. Lond., St. Peter's-park.
Reddall, Osborne Henry, L.R.C.P. Lond., Denmark-park.
Spiller, Walter Charles, M.B. Edin., Trinity-square.
Stubbs, Percy Belford Travers, L.S.A., Canonbury.

Admitted on April 30th:—

Alexander, Sidney Robert, L.S.A., Upper Norwood.
Anderson, Reginald Beam, L.S.A., Bodmin.
Dimmock, Augustus Frederick, L.S.A., Ely.
Drukt, Arthur Barthold, L.S.A., West Kensington-park.
Ellis, William McDonogh, L.R.C.P. Lond., Lee.
Evans, Charles Silvester, L.S.A., Fentiman-road.
Fletcher, Thomas Johnson, M.B., Northwich.
Gilbert, Clarence Edwin Lloyd, L.R.C.P.I., Paddington.
Haydon, Hillyard William, L.S.A., Highgate.
Pope, Henry Alexander Lepthairia, L.S.A., Donegal.
Pugh, John Williamson, L.S.A., Llabon.
Simpson, George Augustus Garry, L.S.A., Warwick-road.
Toogood, Frederick Sherman, L.S.A., Southampton.
Wilson, John Robert, Caistow, Lincs.

Admitted on May 3rd:—

Buckland, Sydney Charles, Wimbledon-park.
Gage-Brown, Charles Herbert, M.B. Edin., Sloane-street.
Hildyard, Robert Loxham, L.S.A., Newcastle-on-Tyne.
Peake, Solomon, L.S.A., Coventry.
Potts, Walter Alfred Beevor, L.S.A., Amersham.
Shackleton, Thomas Francis, L.S.A., Catford Bridge.
Smith, Henry Craven, L.R.C.P. Lond., Torquay.
Sealy, Francis Marmaduke, L.S.A., Godberton.
Turner, Henry Sweetman, Wandsworth-common.
Williams, David, L.S.A., Carmarthen.
Wright, Alfred John, L.S.A., Mackfield-terrace.

Admitted on May 4th:—

Baumgartner, Henry Spelman, L.S.A., Newcastle-on-Tyne.
Bullen, Frederick St. John, L.S.A., Dulwich-road.
Gaston, Harry Percival, L.S.A., Nettlebed.
Gaudin, Francis Neel, L.S.A., Staines.
Locke, George, L.S.A., Kingsland-road.
Lucy, Reginald Horace, M.B. Edin., Worcester.
Norris, Edwin John, L.R.C.P. Lond., St. Peter's-park.
Ozzard, Albert Tronson, Southsea.
Vernon, Arthur, L.S.A., Macauly-road.
Wheatley, James, L.S.A., Huddersfield.

There were 265 candidates for this examination, of whom 90 obtained their diplomas; 72 were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members; 35 candidates were referred for three months, 60 for six months, 4 for four months, and 4 for twelve months; 67 candidates, having previously passed in Surgery, and having passed in Medicine and Midwifery, were also admitted Members.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on April 29th the degree of M.D. was conferred on

Henry Roxburgh Fuller, Gonville and Caius.

And the degree of M.B. on

George Turner, non-collegiate.

UNIVERSITY OF DURHAM.—At the recent examination for certificates of proficiency in Sanitary Science, the following satisfied the examiners:—

Arnold, Ernest Charles, M.R.C.S.
Codd, Arthur Frederick Gambell, M.R.C.S.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the examiners the following candidates have been admitted Licentiates in Surgery:—

J. W. Kenrick, W. C. Leitch, Murdoch Mackenzie, and M. M. Williams, Glasgow Medical School; Joseph Robinson, Edinburgh Medical School; J. W. Lichfield, Charing-cross Hospital; Fred. Stephenson, Owens College; G. F. C. Gardiner, Bristol School.

The following candidates have been admitted Licentiates in Dental Surgery:—

Matthew H. Nisbet, Glasgow; J. Spotswood and F. Dale, Sheffield.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on April 29th:—

Gaudin, Francis Neel, Clydesdale, Staines.
Lewis, Philip King, Adelaide-road.
Wright, Alfred John, Markfield, Leicester.

ON the 3rd inst., a Fancy Fair was opened in aid of the funds of the North-West London Hospital, Kentish-town-road.

THE guardians of the Lewisham Union have been recommended by the Local Government Board to purchase land for building an infirmary.

BERLIN CHARITE HOSPITAL.—The building of the new clinic for children's diseases in connexion with the Charité Hospital in Berlin is about to be commenced.

THE Councils-General of the various French Departments have voted sums of money for the establishment of the proposed Pasteur Institute for the treatment of rabies.

THE death is announced of Dr. C. H. Huxtable, of Auckland, New Zealand, from the effects of chloroform which he had inhaled, as was his custom, for the purpose of procuring sleep.

AT a meeting held at Hastings on the 4th inst., it was reported that a sum sufficient to warrant the committee in formally taking over certain premises, which had been presented for the purpose, as a convalescent home, and opening them as such, had been received.

ON the 4th inst., Mr. D. E. Jones, L.R.C.P., F.R.C.S. Ed., Mayor of Cardiff, turned the first sod of the new series of great waterworks to be constructed in the Taff Valley, near Brecon Beacons, at a total cost of over £300,000.

TESTIMONIAL TO DR. TUCKWELL OF OXFORD.—On Wednesday, April 28th, at the Radcliffe Infirmary, a testimonial was presented to H. M. Tuckwell, M.D., F.R.C.P., by the medical men of Oxford and the surrounding district, together with a few of his old fellow-students and friends, teachers at St. Bartholomew's Hospital. The testimonial took the form of a very handsome gold minute repeater watch, with a choicely-bound presentation volume, containing a short address in the names of the seventy-three medical men who had subscribed. The address ran as follows:—"We,

Digitized by Google

the undersigned members of the medical profession, desrei to convey to Dr. Tuckwell an expression of the regard we have for him as a physician, whose generous and straightforward conduct has done much to elevate the tone of our profession. We wish to express our sincere regret at his retirement from practice, and more especially for the ailment which has necessitated his doing so. We beg his acceptance of this watch as a token of our esteem and sympathy."

WESTMINSTER HOSPITAL MEDICAL SCHOOL (Winter Session).—The following prizes have been awarded: Treasurer's Prize, Mr. L. Lewis; President's Prize, J. R. Plant; Prizes in Chemistry, L. Lewis and E. J. Pritchard; in Medicine, H. B. Brackenbury; in Surgery, C. Burt.

METROPOLITAN FREE HOSPITAL.—The Prince and Princess of Wales have consented to open the new building for the Metropolitan Free Hospital now approaching completion in the Kingsland-road. The ceremony will take place during the ensuing summer, at a date to be fixed by their Royal Highnesses.

ON the 17th and following two days, it is intended to hold at Prince's Hall, Piccadilly, a bazaar in aid of Morley House Workman's Seaside Convalescent Home. The sum needed to remove the debt on the purchase of the building is £1600, which amount it is confidently anticipated will be obtained.

TRICHINOSIS.—It is stated by a Bavarian medical journal that more than thirty persons have been attacked by trichinosis, in consequence of eating infected meat. In Wandsbeck also there has been an outbreak of the same disease, two persons having died of some thirty who have shown symptoms of trichinosis.

HOSPITAL SATURDAY FUND.—At a meeting of the board of delegates of this fund on the 1st inst., it was announced that the ladies' outdoor collection would be held on July 17th next, the third Saturday in the month, as last year the earlier time of the street collection and an increased number of collectors resulted in a large increase in the total amount realised.

OLD AGE IN ST. PETERSBURG POORHOUSE.—According to the *Novosti* a man has just died in the St. Petersburg poorhouse at the age of 122; he had been an inmate since 1818. He retained his senses to the last. Indeed, it was only about four years ago that he seemed to fail at all, having till then enjoyed excellent health. There is still living in the poorhouse a soldier's wife, who is shown by documentary evidence to be fully 110 years of age.

ST. JOHN AMBULANCE ASSOCIATION.—A course of ambulance lectures (first aid) for ladies was commenced in Sunderland some time ago, and has just been concluded. The class has been conducted by Mr. W. Percy Blumer, F.R.C.S. Edin., and has been attended by a very large number of ladies, who have so enthusiastically entered into the work that upwards of fifty will present themselves at the examination which is about to be held. At the close of the last meeting Mr. Percy Blumer was presented by the ladies with a case of eye instruments as a token of their respect and esteem and as an expression of their gratitude.

TEMPERANCE CONGRESS AT CROYDON.—This congress was opened on the 4th inst., when, after the inaugural address by Canon Ellison, Dr. Alfred Carpenter delivered an address, in the course of which he detailed the teachings of science as to the true chemical and physiological action of alcohol, and pointed out from authoritative statistics that those who abstained altogether suffered less from ill health and had longer lives than moderate drinkers. Dr. James Ridge read a paper entitled, "Is Total abstinence Reasonable?" and Dr. Norman Kerr followed with a paper on "What we know about Alcohol." Amongst the speakers in the evening was Dr. B. W. Richardson.

THE RECENT VISIT OF THE PRINCESS OF WALES TO TORQUAY.—In reply to a communication on the subject of the proposed public commemoration of her visit to Torquay, the Princess of Wales has stated that she is extremely gratified at this expression of goodwill on the part of the people of Torquay, and that if her own wishes were consulted she would like the memorial to take the form of a ward in the hospital, or of any movement which would prove generally beneficial to the people. Her Royal Highness, however, prefers that whatever is done should emanate from the inhabitants themselves, and that they should do what they consider will be best for the welfare of the town.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the annual meeting of this institution, held on May 1st, the annual report of the Committee of Visitors for the year 1885 was read and adopted. The real and funded property now amounts to above £85,000, entirely derived from the contributions and donations of the members. Twenty-six new members paid their admission fees in 1885. Sixty-three lectures and nineteen evening discourses were delivered in 1885. The books and pamphlets presented in 1885 amounted to about 354 volumes, making, with 464 volumes (including periodicals bound) purchased by the managers, a total of 818 volumes added to the library in the year. The election of officers for the ensuing year terminated the proceedings.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen have been elected Examiners for the ensuing year:—Anatomy and Comparative Anatomy: John Barton, F. A. Nixon, Wm. Thornley Stoker, and Robert L. Swan. Surgery and Surgical Pathology: Charles Ball, E. Stamer O'Grady, William Thomson, and Richard Francis Tobin. Physiology and Histology: E. Dillon Mapother and John A. Scott. Medicine and Therapeutics: M. A. Boyd and R. Hayes. Physics, Chemistry, and Medical Jurisprudence: J. D. Pratt and Samuel H. Webb. Materia Medica, Pharmacy, and Botany: P. C. Baxter and C. H. Robinson. Midwifery and Gynæcology: J. J. Cranny and Henry Croly. Ophthalmology: Arthur Benson and Henry R. Swanzy. Diploma in Midwifery: J. J. Cranny, S. Mason, and Wm. Roe. Preliminary Examination in General Education: F. Davys, Robert Morton, and H. C. Tweedy. Licence in Dentistry: A. W. Baker, Daniel Corbett, jun., Henry Gray Croly, R. Hazelton, Edward Stamer O'Grady, and Henry G. Sherlock.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

AGANOOR, M. S. P., M.B., C.M.Ed., has been appointed House-Surgeon to Gray's Hospital, Elgin, N.B.

CHILD, HERBERT, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the North Bierley Union, Yorks, vice J. H. Naylor, resigned.

GRAHAM, ARTHUR, L.R.C.P., M.R.C.S., has been appointed Third Attending Medical Officer to the Free Dispensary and Provident Medical Institution, Pimlico-road, vice T. H. Battye, M.D., &c., appointed Second Honorary Consulting Physician.

HIRD, THOMAS A., M.B., C.M.Ed., has been appointed Medical Officer for the First District of the Coventry Union.

MURRAY, JAMES, M.B., C.M.Aber., has been appointed Assistant Medical Officer to Murray's Royal Asylum, Perth.

ROBINSON, C. H., F.R.C.S.I., has been elected an Examiner in Materia Medica and Botany to the Royal College of Surgeons in Ireland.

ROBINSON, FREDERICK, L.R.C.P., L.M.Ed., has been appointed Medical Officer for the Eleventh (Thornhill) District of the Dewsbury Union.

ROWLEY, R. J. L., L.K.Q.C.P.I., has been appointed Medical Officer for the Penryn District of the Falmouth Union.

THOMSON, HENRY ALEXIS, M.B.Edin., M.R.C.S., has been appointed House-Physician to the Royal Hospital for Sick Children, Edinburgh.

TRATMAN, FRANK, M.B.Lond., M.R.C.S., L.R.C.P. (late House-Surgeon to the London Hospital), has been appointed Government Medical Officer for the Gascoyne District of Western Australia.

WATSON, THOMAS ALFRED, M.B., C.M.Edin., has been appointed Resident Medical Officer to the Rochdale Infirmary and Dispensary.

Births, Marriages, and Deaths.

BIRTHS.

BARKER.—On the 29th ult., at Harley-street, Cavendish-square, W., the wife of Arthur E. Barker, F.R.C.S., of a son.

CUFF.—On the 4th inst., at 22, Huntriss-row, Scarborough, the wife of Robert Cuff, M.B.Lond., of a son.

MURPHY.—On the 28th ult., at the Barracks, Tipperary, Ireland, the wife of F. H. S. Murphy, Surgeon, Army Medical Staff, of a son.

Digitized by Google

WEBSTER.—On the 28th ult., at Bewdley, the wife of Trevor Webster, M.R.C.S., of a son.

WILLIAMS.—On the 29th ult., at Rose Lawn, Kirkdale, Sydenham, the wife of Albert Williams, M.D., of a daughter.

WILSON.—On the 1st inst., at Sparrows Herne, Bushey, Herts, the wife of Daniel Wilson, M.D., of a daughter.

MARRIAGES.

DARLING—COLE.—On the 27th ult., at Innishannon Church, co. Cork, Quintin Richard Darling, L.R.C.S.I., &c., youngest son of the late Richard Sisson Darling, Esq., of Trinidad, to Letitia Victoria, elder daughter of the Rev. John Harding Cole, A.B., of Woodview, Innishannon, co. Cork.

FRASER—HODGSON.—On the 29th ult., at St. Mary's Church, Beverley, John Joynor Fraser, F.R.C.S.Ed., to Edith, fifth daughter of Colonel Hodgson, of Westwood Hall, Beverley.

GODDARD—SKELTON.—On the 5th inst., at St. John's Church, Wembley, by the Rev. Canon Francis Goddard, M.A., uncle of the bridegroom, assisted by the Rev. A. M. Maynard, B.A., Vicar, Charles Ernest Goddard, L.R.C.P.Lond., M.R.C.S.Eng., A.K.C.Lond., second son of the late Lieut. Colonel Goddard, of Kilburn, to Eleanor Lucy (Nelly), eldest daughter of Samuel Skelton, Esq., of Wembley Orchard, Middlesex.

IRVING—SOUTHEY.—On March 1st, at St. Thomas's Cathedral, Bombay, Surgeon-Major L. A. Irving, youngest son of the late Major-General Irving, C.B., R.A., to Ethel, youngest daughter of the late Colonel Southey, M.S.C.

JONES—CODD.—On the 29th ult., at Christ Church, North Brixton, by the Rev. Canon Hussey, D.D., F. Felix Jones, Surgeon, of Llanfyllin, North Wales, youngest son of the late Dr. Jones, of Llanfyllin, to Ada Louisa, second daughter of A. Codd, of Suffolk Lodge, Brixton.

MATTHEWS—GARLANT.—On the 28th ult., at St. Margaret's, Westminster, by the Ven. Archdeacon Farrar, D.D., Valentine Matthews, of 11, Suffolk-street, Pall-mall, to Maude, elder daughter of the late J. H. Garlant.

MAURICE—CROOME.—On the 29th ult., at St. Philip's, Kensington, William James Maurice, M.R.C.S., of Reading, to Frances Margaret, youngest daughter of the late Rev. Thomas Boys Croome, Rector of Siston, Gloucestershire.

MORITZ — WISE. — On the 5th inst., Siegmund Moritz, M.D., M.R.C.P.Lond., of 155, York-street, Cheetham, to Amelia (Milly), eldest daughter of Emanuel Wise, of York House, Cheetham, Manchester.

ORR—GRAHAM.—On the 30th ult., at Brighton-place, Govan-by-Glasgow, William Alexander Orr, M.B., C.M., eldest son of the late Rev. John Orr, of Kilbirnie, to Katherine Harrison, only daughter of the late Rev. William Graham, of Lochwinnoch.

POOLER—JOHNS.—On the 26th ult., at St. Nicholas' Church, Carrickfergus, by the Rev. Canon Pooler, D.D., father of the bridegroom, assisted by the Rev. Lewis A. Pooler, brother of the bridegroom, Edward Leslie Pooler, M.D., of Newtownards, to Emma Margaret, only daughter of Alexander Johns, of Sunnylands, Carrickfergus.

QUILL—GUNN.—On the 28th ult., at St. Peter's Church, Rochester, Surgeon-Major R. H. Quill, M.D., Army Medical Staff, eldest son of the late Jerome Quill, Esq., J.P., co. Kerry, to Marion M., only daughter of William M. Gunn, M.D., Deputy Inspector-General, Royal Navy.

SHAW—CAVE.—On the 29th ult., at the Parish Church, Kingston-on-Thames, Surrey, Harry Charles Costello Shaw, L.R.C.P.Lond., M.R.C.S., eldest son of F. G. Shaw, Esq., H.M.I.S., of Shedden Hall, Ootacamund, Madras, and Heathburn Hall, co. Cork, to Annie, second daughter of E. J. Cave, Esq., of Norbiton Hall, Surrey.

SKIPPER—GAZE.—On the 29th ult., at St. Augustin's, Highbury New-park, Edward Skipper, M.D., of Tollington-park, N., to Emily Elizabeth, elder daughter of Robert Gaze, Esq., of Mundesley House, Highbury New-park.

SMITH — SHEPPARD. — On the 27th ult., at Holy Trinity Church, Paddington, Herbert A. Smith, M.R.C.S., L.R.C.P., L.S.A.Lond., of Ealing, second son of the late Thomas Smith, Surgeon, of Wheatley, to Myra Dixon Sheppard, eldest daughter of W. Sheppard, Surgeon, of Ealing (formerly of Ashford).

DEATHS

CALDWELL.—On the 27th ult. (from paralysis), Joseph Caldwell, R. Staff Surgeon, R.N., M.R.C.S.

CHAWNER.—On the 3rd inst., at Clay-cross, Derbyshire, Emily Sophia Laird, the beloved wife of Alfred Chawner, L.R.C.P.Lond., M.R.C.S., and daughter of William Clowes, Esq., of 86, Holland-road, Kensington (Chancery Registrar), aged 28.

CUMMING.—On the 27th ult., at Ainslie-place, Edinburgh, William Cumming, M.D., F.R.C.P.E., aged 74.

GARDINER.—On the 21st ult., Arthur Gardiner, M.D., M.R.C.S., of London, late of Belfast and Dublin, aged 68.

MUDGE.—On the 3rd inst., at Middleham House, Ringmer, Sussex, John William Mudge, M.D., Deputy Inspector-General of Hospitals, late of H.M.'s Indian Army, Madras, J.P. for Essex, aged 69.

THOMPSON.—On the 5th inst., at Matheson-road, West Kensington, W., James Thompson, M.D. (formerly of Avenue House, Leamington).

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, May 10.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Dr. B. W. Richardson: Animal Mechanics (Cantor Lecture).

Tuesday, May 11.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
SOCIETY OF ARTS.—8 P.M. Mr. Ernest Hart: Japanese Art Work.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Messrs. Ballance and Edmunds: The Ligature of the Larger Arteries in their Continuity, an Experimental Inquiry.—Mr. Jonathan Hutchinson: Congenital Absence of Hair, with Atropic condition of the Skin and its Appendages, in a Boy whose mother had been almost wholly bald from alopecia areata from the age of six. A series of Microscopic Specimens illustrating the first paper will be on view at 8 P.M.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Mr. Francis Galton: Notes on Permanent Colour-Types in Mosaic.—Prof. Flower: Exhibition of a Nicobarese Skull.—Prof. Macalister: (1) On some African Skulls in the Cambridge University Museum; (2) On a New Ireland Skull.

Wednesday, May 12.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. Buchanan: Certain Alleged Injuries by Vaccination in North Germany.—Dr. Longstaff: Statistics of Hydrophobia in England.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Dr. G. M. Sternberg: Micrococcus Pasteuri (Sternberg).—Mr. F. H. Evans: Photo-micrography by the Woodbury Type Process.—Mr. C. D. Ahrens: New Polarising Prism.
SOCIETY OF ARTS.—8 P.M. Mr. J. W. Bund Willis-Bund: The Proposed Fishery Board.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Mansell-Moullin, Fenton-Jones, and others.—Dr. Arthur Edis: Serous Peritonitis.

Thursday, May 13.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Alkaloids.
PARKES MUSEUM OF HYGIENE.—8 P.M. Mr. R. Warrington: Recent Investigations on Well Waters.
SOCIETY OF ARTS.—8 P.M. Prof. R. Meldola: The Scientific Development of the Coal Tar Colour Industry.

Friday, May 14.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
QUEKETT MICROSCOPICAL CLUB.—7.30 P.M. Exhibition of Micro-photographs with the Lantern, by Mr. F. H. Evans, in the Mathematical Theatre.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Churton (Leeds): Aortic Aneurysm (arch); galvano-puncture five years ago; formation of subcutaneous outgrowths (recent); galvano-puncture; death twenty minutes after last puncture from rupture of first aneurysm into bronchus; soft clot only in sac.—Dr. Carrington: A case of Rheumatic Hyperpyrexia.—Dr. Percy Kidd: Aneurysm of the Aorta; extravasation of blood into the posterior mediastinum, compressing the œsophagus and vagus nerves, and rupture into the abdominal cavity, associated during life with frequent vomiting.—Mr. Pickering Pick: Impaction of Stone in one Ureter, Atrophy of the Kidney of the opposite side.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. John Millar Thomson: Suspended Crystallisation.

Saturday, May 15.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Ernst Pauer: How to Form a Judgment on Musical Works.
SOCIETY OF ARTS.—3 P.M. Prof. George Forbes: Electricity.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

BONE-SETTERS AND THE PROFESSION.

THE *Hexham Courant* lately published a letter in which the writer praised bone-setters and the work they did, concluding by lauding a medical gentleman of the neighbourhood, who not only tolerates the bone-setter, but assists and co-operates with him. This is a little further than we can go. It is not necessary for us to deny that bone-setters have occasionally been of use—from their very ignorance, perhaps. If persons with injured bones think fit to go to them rather than to those who know something about the joints, be it so. But a medical man is mistaken when assisting and abetting a bone-setter.

Morpeth.—We can only refer our correspondent to the Act, 7 & 8 Vict., c. 15, s. 8, or to the Medical Directory, which contains a summary of the duties of the office.

C. L.—The letter is too long for insertion.

AN INCIDENT IN A CASE OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In reference to diphtheria the following occurrence may be of interest.

We have had a rather serious epidemic in an adjoining village, with some very sudden deaths. In the family I am writing about the baby died after less than twelve hours' illness. Two days after three of the other children were attacked; but after some weeks of treatment they all recovered. One of them (James W——, a boy of about eighteen years) went out of doors, and next day was in bed suffering from a subacute pneumonic bronchitis. One day he complained of pain and tightness in the left side, and on coughing a few times he exclaimed, "Mother, it is gone," at the same time spitting up what I now send you in the bottle. I have not examined it, but put it into a solution of carbolic acid, as when I got it in the evening it was far from savoury. This was ejected about three weeks ago. The lad showed a tendency to phthisis, but has been gaining strength and flesh lately. I am indebted to my senior partner, Dr. W. S. Gervis, for a good deal of the above information, he having chiefly attended the lad. Will you please examine and report on the specimen, and oblige,

Yours truly,

Ashburton, Devon, April 15th, 1886. WILLIAM FRASER, M.B.Dub.

*** The cylindrical mass, measuring about two inches long and one-third of an inch in thickness, and one inch in circumference, was found on examination to consist of a coagulum, in which were thickly embedded oil globules, swollen epithelial cells, a few partially digested muscular fibres, and remnants of vegetable tissue. These characters suffice to demonstrate its true nature, which is not a morbid product, but a mass of partially digested food, mainly milk.—ED. L.

SPANISH MEDICINE.

DON LUIS COMENGE has recently published a Spanish work, entitled "Medical Curiosities, preceded by a Discourse on the Flourishing Condition of Spanish Medicine in the Sixteenth Century and its Subsequent Decadence." Though entitled "Curiosities," there is much serious medical history which, as a reviewer in *El Genio Medico Quirurgico* says, deserves to be read and pondered over, such as descriptions of those who have contributed in past ages to the advancement of medical knowledge, and accounts of their doctrines and works. One chapter is devoted to the history of variolous inoculation, which was commenced in Spain by Dr. O. Scanlan, and a parallel is drawn from the arguments of the anti-inoculationists of those days and the anti-vaccinationists of the present time, together with the opponents of Ferran's anti-cholera inoculations. With regard to decadence of Spanish medicine since the sixteenth century, the reviewer referred to remarks: "Until instruction undergoes a complete change, we shall not advance a step in the direction of progress. Medicine has for some years been in the stage of pure experimentalism, and we Spaniards experiment but little or not at all. In the professoriate there are, it is true, many men of profound knowledge, who are an honour to contemporary medicine; but there are still others who talk to their students about the pathogenetic importance of phlegm, and lecture on typhus, cholera, and other infectious diseases just as teachers at the commencement of this century might have done." With such elements in the professorial staffs, the author and reviewer agree that but little progress is to be hoped for.

R. L., M.D.—We have explained our position, and must decline to open our columns to a discussion of the facts, or fictions, of religious belief.

Simon G.—The coroner has absolute discretion in such a case. Our correspondent does not state the circumstances in which A handed the case over to B.

SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—Having had some sea experience within the last few years, I would fain join the multitude who have something to say on the vexed question of sea-sickness.

First, then, I want to insist that sea-sickness is simply a form of migraine which is caused by jarring of certain medullary centres and of the membranous semicircular canals by a peculiar external motion. Considered from this point of view, many symptoms which otherwise seem inexplicable are easily accounted for, and its treatment may be rationally conducted very successfully. The sea migrainal-nerve disturbance principally affects the liver chologenetically, but it also increases the secretion of saliva and gastric mucus. The quantity of bile secreted in each individual case is at first very large; but as the case becomes chronic, it is naturally lessened, the secreting cells becoming exhausted. Hence the congested, jaundiced eyes, the bile-stained urine, the bilious vomiting and occasional bilious diarrhœa, in cases of *mal de mer*. The distressing paroxysms of qualmishness are caused principally by the regurgitation of bile into the stomach, and are invariably relieved by emesis. Just before the emesis of bile takes place the heart's action often becomes irregular and depressed. I have seen a lady nearly dead from cardiac failure in sea-sickness. The cause of this, probably, is as follows. The gastric nerve-endings of the pneumogastric, if I may so speak, become irritated by the regurgitated bile, thereby causing cardiac reflex inhibition through the inhibitory branches of the same nerve.

Now, as to treatment. All the much-vaunted specifics, such as bromides, &c., are worse than useless. Common-sense treatment which is palliative I have found answers admirably. First, let the patient lie down on his (or her) right side, with the head low. This has a twofold effect. It relieves the irregular tensive action of the semicircular canals, and to a great extent prevents regurgitation of bile into the stomach. The sufferer should abstain from stimulants, except with food, as the blood is already loaded with bile excreta. A little effervescent citrate with hydrocyanic acid may be taken occasionally (the latter only if the pulse be not depressed, as it has itself a cardio-inhibitory action). If there be much cardiac depression, a minute hypodermic injection of atropia will be found useful. The dry-food *régime*, so popularly believed in, is probably a mistake, as the stomach rejects such food before the assimilation of any of it can have taken place. A bowl of plain soup, a little dry toast, and a glass of port wine taken quickly in the position recommended will often be found successful. If that fail, iced chicken jelly and a glass of iced champagne will frequently be retained. The patient, it is needless to state, should have plenty of fresh air.

I am, Sir, yours truly.

China. M.D. SURGEON, R.N.

EPISTAXIS.

To the Editor of THE LANCET.

SIR,—A young gentleman (a farmer), otherwise apparently in perfect health, suffers great inconvenience from epistaxis, occurring almost every morning and during the day on the slightest irritation to the nose, which is somewhat painful in frosty weather. I have tried every remedy I know of in vain, and shall be very thankful for any suggestions as to treatment. I am, Sir, yours faithfully,

St. Mary Cray, Kent, May 3rd, 1886. ALEX. SHANNON.

DIGITALINE.

M. LAFON, having examined various specimens sold under the name of digitaline, finds that a number of these occurring in commerce in France, both as amorphous and crystalline powders, are innocent of even a trace of the alkaloid, but M. Nativelle's digitaline, though amorphous and yellow, is, chemically speaking, identical with Merck's digitoxine.

Dr. Waldemar-Marian Phillipowitch (Odessa).—We regret we are unable to comply with the request of our correspondent.

Dr. Vasity (Bucharest).—We cannot extend our exchange list.

F. A. W.—We do not give medical advice.

HYDROPHOBIA: FRESH SUGGESTIONS.

To the Editor of THE LANCET.

SIR,—At the present time, when the greatest minds of the medical and scientific world are likely to be in a special manner directed to the problem of successfully dealing with hydrophobia, we have good reason to hope that something of real, lasting, practical benefit to suffering humanity will be the result of their investigations. I confess to a sanguine expectation that the method of treatment suggested and adopted by M. Pasteur will be found ultimately to succeed; and if such should be the case, we shall all ere long no doubt be placed in a position enabling us to "Go, and do likewise." Meanwhile, this method must be looked upon as being *sub judice*, and while it so remains it behoves each and all of us to exercise our best knowledge and judgment in such a matter, seeing that from the unusual prevalence of the disease in many parts, it is not unlikely we may have to deal with it. Fortunately for us in these northern parts, hydrophobia is of so rare occurrence as to be almost unknown (a single case has not been seen by my senior principal, Dr. Manson, in the course of a busy practice extending over fifty years); but in order to be prepared, should an undoubted case of rabid poisoning present itself, I have resolved upon the following line of treatment.

Local Treatment.—Locally, if seen on the instant, and if possible, complete arrest of circulation in the part by a tight ligature above the wound. After ligature and careful washing, as speedily as possible freeze a circle of skin at some distance from the wound by means of Richardson's ether spray, and, if practicable, excise the part, encouraging hæmorrhage to a judicious degree. When the wound is situated in a part where the application of a ligature would be impossible, a thin-edged tumbler, or other similar contrivance wide enough to include the wound, and firmly pressed down, would serve the purpose of arresting the circulation. The skin might then be frozen around the outer edge of the tumbler, and excision effected. The effect of the ether spray, besides anæsthetising the part for the knife, I presume, would be to interfere with the activity of the absorbents, and so delay general infection. After excision, I propose making a thorough application to the wound of a strong solution of chloride of zinc (℥ii. to ℥i.), which is capable of permeating the tissues for a considerable depth, and is well known for the property it has in rendering wounds incapable of putrefaction for several days, even when in contact with septic material. Should excision of the part prove impracticable, reliance should be placed on the other measures—viz., arrest of circulation by the means above stated, thorough washing of the wound, freezing of the surrounding parts, encouragement of bleeding (by cupping-glasses, &c.), and the subsequent use of chloride of zinc.

General Treatment.—In view of the fact that profuse secretion of a very viscid saliva constitutes a prominent symptom of hydrophobia, with the fact that it contains an abundance of the virus, and the probability that it is the only secretion that does contain it, it has frequently suggested itself to my mind that pilocarpine (from its very decided influence on the salivary secretion) might reasonably be conceived capable of eliminating the virus in the undeveloped disease, by imitating in its action what appears to be the chief effort of nature to rid itself in the developed disease. I suggest that it should be administered by the hypodermic method, and that its physiological effects be kept up for a period of forty-eight hours, or longer, immediately succeeding inoculation. The diaphoretic action of the drug (probably also beneficial) might be increased by the ordinary vapour or blanket bath, with the free use of diluents. In the treatment of the developed disease I would adopt the general measures as above stated, hoping thereby to assist the natural efforts at elimination of the poison, and so tend to the relief of symptoms by removal of the cause. In addition I should depend on bromide of potassium and chloral hydrate as sedatives—bromide of potassium, from its undoubted action in lessening the irritability of sensory nerves, being, I think, particularly indicated.

I am, Sir, yours faithfully,

Banff, April 14th, 1882. JAMES BARRON, M.B., C.M.

TREATMENT OF GONORRHŒA CHRONICA BY MEANS OF GROOVED BOUGIES.

To the Editor of THE LANCET.

SIR,—Referring to the letter of Dr. Atkinson in your issue of April 17th, page 769, I beg to state that there is no doubt that some cases have been cured by injections applied by a suitable catheter. But, on the other hand, I accept Dr. Atkinson's confirmation of that many cases of healing are taken place with my grooved bougies. This is all I maintain. Some cases are better for one method, others for the other.

I am, Sir, your obedient servant,

Berlin, May 2nd, 1882. DR. LASSAR-CASPER.

UNQUALIFIED MASSEUSES IN VIENNA.

A VIENNA medical journal complains bitterly of the patronage afforded to quackery in the form of massage by medical men of the highest position—professors, lecturers, and others—who assist in setting up their female relatives or servants in business for themselves as masseuses. Massage is not a treatment which can safely be trusted to a lay person. It requires a knowledge not only of normal anatomy, but of the nature and course of the disease from which the patient is suffering. As these persons frequently practise without reference to a medical man, it is not surprising that they sometimes go on "massiring" a malignant tumour or a case of tuberculous periostitis for weeks or months, and so do a great deal of harm. "It is a great pity," continues the journal referred to, "that people have taken it into their heads that it is undignified for a physician to practise massage. Men like Mosengeil in Bonn, Busch in Berlin, Bergmann in Stockholm, Johnsohn in Copenhagen, &c., have not been above practising massage. It is greatly to be desired that the medical authorities may see their way, in the interest of the suffering public, to bring this new form of quackery within narrower bounds."

Medicus.—Witnesses are not generally paid for evidence before a Select Committee.

SEVERE CASE OF URTICARIA.

To the Editor of THE LANCET.

SIR,—The following case may be of sufficient interest for insertion in your journal.

R. B——, a man about forty years of age, came to me a week or two ago, complaining of an acute swelling about the groin and penis. On examination, I found the penis very much swollen, and presenting a condition of phimosis. The cellular tissue of the scrotum was also largely infiltrated with serum. The groin on both sides and the upper part of both thighs presented a brawny, erysipelatous appearance, with the skin tight and angry-looking—indeed, at first sight the whole appearance seemed alarming. The other parts of the thighs were more or less covered with wheals and an erythematous rash, as were also the front of the abdomen and the loins. The rash and wheals did not extend above beyond the level of the umbilical line, nor below beyond the knees; the chest, legs, and arms presenting no abnormal appearance. He had a furred tongue, and a quick, full pulse; the temperature was about 100°. It was evidently a case of urticaria, and to all appearance a very severe one. Within twenty-four hours, after complete rest in bed, the administration of a five-grain pill of colocynth and hyoscyamus, and an alkaline mixture, with light diet, the whole thing had cleared away. The patient had partaken very freely of mackerel at supper the previous night.

The peculiarities of the case appear to me to be the localisation of the rash and swelling, its alarming appearance, and the rapid subsidence of the severer signs. I have in my description rather understated the general appearance and the extent of the swelling. The patient had been the subject of acne vulgaris; and I would say in connexion with this that I have noticed that all, or nearly all, patients who suffer from medicinal rashes, or rashes produced by errors of diet or chill, are, or have been, the subjects of acne of sufficiently severe character to leave a few pits or scars as evidence of its past severity. I have lately seen the iodide rash in a lad of eighteen, and a slight rash from atropine (⅛₀ gr. hypodermically) in a woman about forty. The former had severe acne at the time, and the latter showed old scars of it on the shoulders. (The woman, as a result of the dose of atropine mentioned, also suffered from marked delirium and dimness of sight, with some dilatation of the pupils, but had no thirst or dryness of the fauces.) I think the consideration is worth noting, as no doubt the subjects of severe acne must at all times suffer from a certain mal-assimilation of food, with an accompanying deterioration of the quality of the blood; therefore I shall in future advise such subjects to be careful in their diet, and be careful myself in the administration to them of certain drugs.

Believe me, Sir, your obedient servant,

Pangbourne, Reading, May 1st, 1882. W. T. FREEMAN.

A RUSSIAN VIEW OF THE BERLIN M.D.

THE Berlin correspondent of a Russian medical journal makes merry over the mediævalism still lingering in Prussian universities, and especially over the ceremony of the disputation for the doctor's degree, with the dean in his red robes merely playing propriety with classical Latin phrases, and the candidate with his three "friend opponents," who have settled with him about the subjects to be discussed beforehand. All this, says the correspondent, is very different from the procedure in Russia, where there are no traditions handed down from the Middle Ages to be attended to, and the professors are much stricter about allowing candidates to pass, besides which, the young aspirant has, instead of friendly opponents as youthful as himself, masters of the art of wrangling to contend against. Altogether, the writer seems to think it hard that the title of Doctor can be obtained on so much easier terms abroad than in Russia. Comparisons are proverbially odious. It would be instructive to see what Berlin graduates acquainted with the proceedings at Russian universities have to reply to the criticisms of their Russian visitor.

L.S.A.—So far as we are aware, registration only is required

PREVALENCE OF ANEURYSM AMONGST FOREIGN RESIDENTS IN CHINA AND JAPAN.

AT a recent meeting of the Sei-I-Kwai, Dr. Eldridge, in reporting a case of aneurysm, called attention to the fact that, for some reason as yet unexplained, residents of European blood in the Chinese and Japanese ports are perhaps more subject to this disease than are any other people on earth. In Yokohama, during seven years, aneurysm ranked fourth amongst the causes of death, every case included in the return being undoubted, and nearly all submitted to post-mortem examination.

A Student has not enclosed his card.

Mr. Cantlie is thanked.

"KISSING THE BOOK."

To the Editor of THE LANCET.

SIR,—As all medical men who do not belong to the Society of Friends are expected when giving evidence in England to kiss the Bible, I would suggest that when taking the oath they should simply apply the thumb which holds the Bible to their lips, and not the Bible itself; or they might only bring the Bible within an inch or two of the mouth. The former method, for obvious reasons, is preferable. I may state that the Scotch oath is administered by the judge, the witness holding up his right hand and repeating the words of the oath after him. Dr. Gresham therefore need not cross the Atlantic to take a leaf from our American cousins' book.

I am, Sir, yours truly,

May 3rd, 1886. DANIEL MOWAT, M.B., C.M.

SKIN GRAFTING FROM THE FROG.

Inquirer.—So far as we know, the practice of skin grafting from the frog was first practised in this country by Dr. William Allen of Leadgate, Durham. See his letter in THE LANCET of Nov. 15th, 1884, p. 875.

Dr. John Roberts.—We agree with our correspondent, and shall be prepared to support the amendment he refers to. We should be glad to publish a letter from him on the subject.

A Constant Reader.—Roscoe.

"THE SUPPLY OF THE PROFESSION."

To the Editor of THE LANCET.

SIR,—In the list of medical schools with more than twenty entries published in your journal of last week, I beg to point out that you have omitted the Middlesex Hospital.

I remain, Sir, your obedient servant,

W. CAYLEY,

May 5th, 1886. Treasurer, Middlesex Hospital School of Medicine.

*** The figures are those officially given in the Register of Medical Students, and they do not in every case correspond with the actual number of entries, since many students are registered prior to joining a school.—ED. L.

THE MORPHIA HABIT.

To the Editor of THE LANCET.

SIR,—Could any of your readers give me any information that would prove of use in the following case?

A lady about sixty years of age has taken morphia (1 in 25) hypodermically for some years. During twenty-four hours she will have five or six injections, varying from three to five minims, and occasionally to eight minims. She is now very anxious to give it up, as the forearms and some distance above the elbow are a dense cicatrix, and an eczematous condition of both hands is developing. Would cocaine be useful? Any suggestions would be gladly received by,

Yours obediently,

May 4th, 1886. YOUNG PRACTITIONER.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Address
ON
MEDICAL SURGERY,
OR THE
RELATIONSHIP OF MODERN SURGERY TO PRACTICAL MEDICINE.

Delivered before the Manchester Medical Society.

BY JAMES HARDIE, F.R.C.S. ENG.,
PRESIDENT.

GENTLEMEN,—Medicine, in the usual acceptation of the word, is that branch of the healing art which deals with disorders of the viscera of the three cavities of the body, and surgery is that which deals with affections of the limbs and the parts of the body external to those cavities. This very crude distinction is not, nowadays at least, literally correct; neither does it attempt to indicate their essential characteristics, nor the real relationships which exist between the two. I fear that it can scarcely be claimed for the art of surgery that it occupies an equal platform to that of medicine, as might be inferred from this definition. Is it not the case that surgery, in reality, apart from its concern with the accidents of life, is but a last resource, after the failure of medicine? Take the surgery of the limbs if you will—the surgical diseases of the limbs. What are they? Are they not the outcome of the failures of medicine? What of strumous joints, of tubercular diseases of the bones? Is it not the case that they are the result of a failure of the art of medicine? They are the outcome of a depraved condition of the body generally, which it is the province of medicine proper to deal with and prevent, as much as it is its duty to foresee and prevent, in the same cases, the formation of tubercle in the lungs. As surgeons, the tubercular constitution meets us at every turn, when it has passed the stage of a mere condition of the blood-forming organs, or whatever else its ultimate pathology may be.

> "Strangely visited people,
> All swollen and ulcerous. Pitiful to the eye,
> The mere despair of surgery."

Or take rickets. Why should the surgeon have his cases of genu valgum, or bent tibiæ, or twisted spine, had medicine been powerful enough to have arrested the disease, while it could only be spoken of as a disorder of nutrition? What, again, of aneurysm? A man comes to us with an aneurysm of his popliteal artery. Who will deny that it was the province of medicine to have prevented that man's arteries from becoming atheromatous, and to have kept his tissues healthy, until he dropped, like an autumn leaf, sere and yellow, into his grave? I will even take the cases of congenital deformities and tumours. I am not now going to discuss the pathology of either the one or the other; but when the time comes when it shall be fully known, I doubt not, and I think we cannot doubt now, that it will be traced to an evident departure, in one generation or another, from the laws which regulate the perfect formation and development of the healthy frame.

I do not know that medicine will ever be greatly successful in *curing* disease. We can cure syphilis; and, if cured sufficiently early, it may do no harm to the organism. Perhaps it is that we can cure hydrophobia; and if so, it may be that we shall be able to cure zymotic fevers. But these are cured by killing them and getting rid of them, as we cure a tape-worm with a dose of filix mas. We may cure a disease which attacks the body by killing it before it has done much or any harm. But medicine, so far as we can tell at present, must concern itself chiefly with prevention. Most men may not go on drinking whisky without serious damage to their liver and kidneys; and this medicine cannot prevent. The antidote cannot be taken in alternate glasses; the whisky must be locked up, or the morbid impulse towards it must be restrained. So with constitutional disease. As some men are born with an organism so constituted that they are the victims of vicious habits, a fact which the physician has to recognise and deal with, so others are born with organisms so constituted that they are prone to, or become the prey of, tubercle, or of rheumatism, or of gout, or of rickets, or of a carcinoma, or of a sarcoma. This it is the business of the physician to detect, and to direct such a man so to live that the exciting cause of the development of any of these things shall not come in his way. Once developed, the *cure* of his disease is another and much more difficult matter; and so it happens that in time the surgeon has to be applied to to relieve him of his deformity, of his stone, or of his tumour.

Surgery, then, in its relationship to medicine consists in dealing with the gross results of diseased processes; and it will be interesting to us now to survey the progress which it has made in helping medicine to deal with such morbid results. For this purpose I shall revert to the old distinction between medicine and surgery, which I discarded at the beginning of my address, and leave out of consideration altogether the surgery of the parts of the body other than the three great cavities, inasmuch as, from the beginning of medicine, these have been claimed by surgery proper, without regard to the pathological cause of the maladies affecting them.

When surgeons began to extend their domain from the orifices of the body, where diseased structures might be seen with the eye or felt with the finger, the operation of lithotomy was that to which their attention was first directed. In the case of a stone in the bladder, the painful character of the symptoms, while urgently calling for relief, at the same time proclaimed, in many cases at least, the nature of the complaint, which was established beyond doubt when the sound was introduced into practice. In this operation, the accessibility of the organ from the surface, without implicating important parts, and the free drainage from the incision, would no doubt make it quite a successful one, even in the days of rude surgery; and if the case turned out to be one of cystitis instead of stone, it is to be supposed that relief may sometimes have been accidentally afforded.

The same considerations of pain and urgency of symptoms, while the diagnosis was also certain, would lead to the Cæsarean section being undertaken *in extremis*. But here the circumstances of the operation were much more grave. The opening of the peritoneal sac alone—a dangerous vortex to be engaged in, to say nothing of the complications entailed by emptying the uterus—renders this an operation demanding all the resources of the surgery of the present day to offer even a slight chance of success, and one can therefore imagine how timorously it would be engaged in. Compare with this the case of a patient suffering from internal intestinal obstruction. Here, again, there are great urgency of symptoms and grave danger. On the other hand, however, besides the dreaded peritoneum, there lay the doubtful diagnosis, and the possibility that, by waiting, the symptoms might pass off and recovery take place. Thus, while urgency of symptoms and danger to life might impel the surgeon to undertake an operation on the abdominal cavity, yet the grave results to be apprehended from opening the peritoneum barred the way, and the operation could only be justified, in the minds of most, by certainty of diagnosis. This impotence of surgery in dealing with the peritoneum undoubtedly reacted unfavourably on medicine, in so far that it afforded no encouragement to refinement of diagnosis. The operation of ovariotomy did much to deprive the peritoneum of its terrors. The nature of ovarian disease began to be studied, and through the work of Clay in our own town, more than by anyone else, it began to be the recognised duty of the surgeons to attempt to give relief. Thus, something began to be known of the causes which induce peritonitis, and of the methods of preventing it. Much information was gained, and the way paved for the further developments which have occurred under our own eyes. In the case of the colon and kidneys, abdominal organs which might be reached from behind without opening the peritoneum, their depth from the surface, and the danger of infiltration of pus in the surrounding cellular tissue, were considerations almost as repellent as the danger of peritonitis by the abdominal incision.

As regards the thoracic cavity, up to a few years ago nothing surgical was attempted beyond tapping the pleura, or, it might be, in the case of an enterprising physician, the pericardium. The eminently satisfactory result of the

Digitized by Google

former at least of these operations when the fluid was simply serous, was sufficiently evident—a literal carrying out of the figurative language of Shakespeare:

> "Canst thou not .....
> Cleanse the stuffed bosom of that perilous stuff
> Which bears upon the heart?"

In the case of purulent effusion, however, surgery remained for long blind and halt, so that in such a case recovery was due rather to happy accident than to an intelligent perception of the difficulties to be overcome and the method by which this was to be accomplished.

Of surgical assistance in disease within the cranial cavity up to the last two or three years the record is almost a blank. On their own account, indeed, as in the case of fractures of the vault, surgeons had been accustomed to deal with injuries to the brain; but with the single exception of tapping the fontanelles in chronic hydrocephalus, I can recall no operation by which an attempt was made to render service to medicine.

And so, sometimes by improved means of diagnosis, sometimes by greater surgical skill, we might have gone creeping on along the fringe of medicine proper, when nineteen years ago Lister, for the first time in the world's history, by applying to surgery the masterly researches of Pasteur on the phenomena of fermentation and putrefaction, enabled us to understand how the various disasters which barred the progress of surgery occur, and some years earlier Chassaignac introduced his drainage-tubes into practice. The peritoneum is opened now without Listerian details, and with marvellous success. Why not before the time of Lister? I am not concerned to uphold the *manner* of Lister's work, but this I do hold, that it was Lister who first taught us that it was by the injurious action of ordinary air on dead organic matter that the host of calamities which hovered around the path of the surgeon was to be accounted for. We thus know the vast importance of the utmost cleanliness in opening a serous sac, and of the protection of it from the entry of foreign material. Thus was Marion Sims able, in 1877, to cut down on the gall-bladder, and by carefully stitching the edges of the incision into it to the wound in the abdominal wall, to prevent the escape of foreign material into the peritoneal sac. This was the first of a large and important series of operative proceedings on the abdominal cavity; and although his patient died, yet to Sims undoubtedly belongs the merit of having shown how to deal, not alone with such cases, but with the similar ones of hydatids of the liver, adherent cysts, chronic abscesses, and so on. But what if foreign or dead material does enter, in spite of our precautions? We may prevent, in ordinary circumstances, the contents of an ovarian sac, or of a gall-bladder, or of an abscess from gaining access to it, but we cannot always prevent the access of blood. It is only now that we are beginning to assess at its true value the invention of Chassaignac. The advantage of draining the peritoneal sac when blood or serum happened to collect in the pelvis was fully demonstrated by Keith, who, if the temperature began to rise in his ovariotomies, boldly incised the pouch of peritoneum forming Douglas's space, with the result of withdrawing a quantity of bloody serum and the immediate amelioration of the condition of his patients. Nowadays, when any fear whatever exists, in these or other operations, of blood collecting in the pelvis, the precaution of inserting a glass tube, on the table, is invariably followed.

Thus, then, the dread of wounding the peritoneum, so long the bugbear of abdominal surgery, has been disposed of, and surgeons are ready, awaiting the summons of the physician. The art of diagnosis has thus been wonderfully quickened, so that diseases which at one time were scarcely ever heard of have become matters of every-day occurrence. The brilliantly successful career of Mr. Tait, in the field of abdominal surgery, must be present in the minds of most of my hearers. His operative successes on the ovaries, on the Fallopian tubes, on the liver, and other parts, show most strikingly the extraordinary advances which surgery has made in this region during the last few years. The kidney and ureters have shared with the other viscera in the general advance. It is no longer necessary for a stone to have reached the bladder before it may come within the reach of the surgeon's art. I well remember—it may be some thirteen or fourteen years ago—a remark made by our distinguished President, Sir William Roberts, in a meeting of this Society, on a case in which a renal calculus was known lying in the ureter by the side of the uterus. The small amount of inflammation had cost the patient his life, and Sir William was acute enough to remark that he thought that, had such a condition been diagnosed, it would have been quite possible for a surgeon to have cut down on the stone, and either to have extracted it or pushed it into the bladder. It is pleasant to recall this incident, for it impressed itself on my mind as a shrewd remark, and it foreshadowed what we are fain to do now. It is scarcely within the scope of my purpose at present to enter into details concerning the operative surgery of the kidney. Nephrotomy and nephrectomy are operations firmly established, and it may be said regarding them that operative surgery has overtaken and is in advance of diagnosis. I fear the happy time has not yet come when the physician shall no longer consider that he has any more to do with the kidney than with the bladder; and therefore we want him to tell us, more precisely than he frequently does, what it is that is the matter. Has the patient two kidneys or only one? Is it an impacted calculus or an abscess? A cyst, or nothing at all?

What of acute intestinal obstruction? To my mind this is still one of the least satisfactory of the medical affections of the abdomen which the surgeon has to deal with. We are called to a patient with a belly swollen and tympanitic; we get a confused history, and are left to grope about as best we can. Nothing comes of it. We know not whether it is a case of ileus, of intussusception, or of strangulation. We perform an operation, and the patient too often dies unrelieved. In this condition there is still much to be done and perfected by the physician in the direction of diagnosis.

The various operations for the amelioration of symptoms in incurable stenosis of the œsophagus and pylorus, gastrostomy, duodenostomy, and gastro-enterostomy, have been attended with a gratifying amount of success. The relief from pain and impending starvation has frequently been so marked that it would be unjustifiable to deny it to a suffering patient, though a respite only from the advance of disease be obtained. This much may, I think, already be affirmed for cases which are at all favourable, though the varying details of operation, as required by the varying conditions to be met with, are points which are still *sub judice*. So, too, let us bear in mind the possibility of digital divulsion of non-malignant stricture of the pylorus and of excision of gastric ulcer.

As regards more grave operative procedures within the abdomen, such as those for removal of malignant disease affecting the pylorus (of which our secretary, Mr. Southam, has recorded a striking case), the duodenum, or other parts of the intestinal canal, the excision of the spleen or of portions of the pancreas, I shall say little. At present I fear we can scarcely regard them as more than bold attempts, with the advantages of modern surgery, to rescue the sufferers from impending death; and when one bears in mind how soon the lymphatic glands become implicated in the case of cancerous disease, I feel that, in that case at least, it is very questionable whether it will ever be worth anyone's while to undergo the immediate risks of such severe operations, with so little assurance of positive future benefit, until we know much more than we do at present of the nature of cancer.

Turning now to the surgery of the thoracic cavity, we find that it is to the use of the drainage-tube more than to anything else that the advances of the past few years are due. Given a case of empyema of recent formation, its complete cure by means of antiseptic drainage is within the power of anyone only moderately skilled in surgical procedures. The lung, being relieved from the pressure of the pent-up fluid, gradually expands and assists in the obliteration of the abscess cavity. But in older cases, in which the expansion of the lung is more or less prevented by thickening of the pleura or the formation of bands of organised lymph, there is a physical difficulty to such a process, and many a one has remained on our hands in a condition of half cure, with a sinus leading into a large suppurating cavity which we were powerless to close. To Estlander belongs the merit of showing how such a state of matters is to be dealt with, and there can be no doubt that his ingenious device of removing portions of the ribs to allow of the otherwise rigid thoracic wall falling in to meet the bound-down lung is a notable addition to the art of surgery. Tapping and drainage of fetid cavities in the lung, and the excision of broken-down and harmful portions of the lung itself, are also operations of which the feasibility has several times been demonstrated.

Much interest has lately been gathered round the medical surgery of the cranial cavity. Gravely to propose to excise

Digitized by Google

a tumour of the brain would, only a few years ago, have been received with a smile. But we have got beyond this now. Tumours of the brain have been excised, and will be excised again. We are now endeavouring to find out how far we may safely go in this direction. The *sine qud non*, in operating on the brain, is of course accurate previous localisation of the lesion, and this the advance of neurological science within the last few years has rendered a comparatively easy task. A careful consideration of the nervous phenomena of the case now enables the expert in neurology to determine with the greatest exactitude both the situation and the probable character of a brain lesion. As regards the former, it can scarcely be anticipated that the boldest surgeon will ever venture beyond the accessible parts of the cortex, but with this limitation enough has already been done to show that brain surgery is destined to occupy an important and legitimate position in the future. It may not yet be possible to predicate, in every case, whether the lesion be situated primarily within the brain substance or on its envelope, nor whether it be inflammatory in character or a neoplasm. I venture to think, however, that the gravity of any case, from a surgical point of view, will depend mostly on the answer which may be given to the former of these two considerations. The latter is probably of less importance, apart from the general question of the comparative curability of inflammatory and neoplastic deposits. Obviously it will be less dangerous to remove an inflammatory thickening of the dura mater or a tumour growing upon it, which simply lies upon, and perhaps has induced some absorption of, the brain substance, than to incise the latter and remove a deposit embedded in its substance. A considerable number of successful cases of the former class of operation have already been recorded, notably by Dr. Macewen, of Glasgow. Of the latter, the original case of Dr. Bennett and Mr. Godlee is the best known, and although unfortunately terminating in death, yet its satisfactory progress for a considerable time showed that the fatal event was due to accidental and preventable causes rather than to anything necessarily inherent to the nature of the case. At the same time, I think I shall be borne out by every surgeon of experience when I say that, while in no department of surgery is a failure of strict antiseptics more likely to be disastrous than when brain matter is exposed, in none is it more difficult to conduct a case through the many pitfalls to which we are exposed to a satisfactory termination. Hence the vast importance of a speedy closure of the wound, which is precisely what cannot be attained in such cases, inasmuch as the cavity resulting from the operation has to fill up by the secondary process of healing.

In connexion with cerebral surgery, I may also allude to the suggestion of Dr. Alexander, of Liverpool, to treat certain cases of epilepsy by ligature of the vertebral arteries. Although his later experience has not quite supported his earlier, yet the proposal, and the partial success which has attended it, afford ground for believing that by surgical means it may be possible to influence materially morbid conditions of the central organ of the nervous system. The employment of nerve-stretching, also, in various forms of peripheral neuroses, is now an established and satisfactory operation, of which you have seen several examples at our meetings.

In thus hastily and imperfectly reviewing the relationship of the surgery of the last few years, considerably fewer than those during which I have been a member of this Society, one cannot but feel that its progress has indeed been a triumphant one. The whole course of the alimentary canal has come within its province, the blood-forming, the secretory, and excretory glands have, every one of them, become the prey of the surgeon's knife. So, to a considerable extent, has the entire circulatory apparatus, and even the seat of the intellect itself. To speculate as to where this will end were vain; for even now the art of surgery is not limited to the mere lopping off and casting away of these failures of the art of medicine. Its influence on the economy is manifest. Can we not cure epilepsy by trephining the skull, and thereby modify the whole future mental state of our patient? Can we not prevent or cure amyloid degeneration by cutting off a suppurating joint, and thereby profoundly alter the whole subsequent nutrition of that child? Can we not prevent the occurrence of the cancerous cachexia and irretrievable ruin by the timely removal of an epithelioma? Can we not believe that in the near future we shall be able to prevent the malignant cachexia of lymphadenosis? Who shall deny that it may be surgery, and not medicine, which shall first show how the development of cancer or of lymphadenosis is to be prevented? May not the spleen be prevented from spoiling the whole mass of blood by a ligature being placed around the splenic artery? Who knows how the congenital predisposition to rheumatism or to gout may not be artificially prevented from declaring itself, and thereby bringing in its train the multitude of secondary ills which its subjects are liable to? How shall "dyspepsia" be treated in the next century? By digesting our food in our stomachs as we do in a test tube, or by a surgical operation on the pancreas? Speculative problems these; but we cannot tell how closely surgery may yet walk hand in hand with medicine and be concerned in the control of the very acts of assimilation and tissue formation.

PRACTICAL REMARKS ON EXTRACTION OF CATARACT.[1]

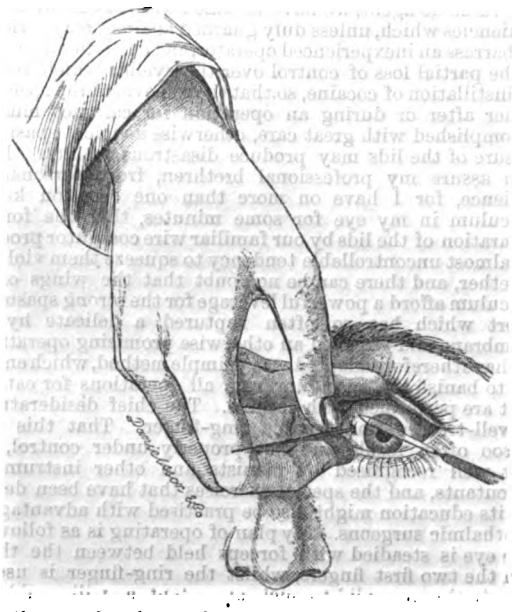
BY ANDERSON CRITCHETT, M.A. CANTAB.,
OPHTHALMIC SURGEON TO, AND LECTURER ON OPHTHALMIC SURGERY AT, ST. MARY'S HOSPITAL.

I BELIEVE that I am not overstating the case when I affirm that before the introduction of cocaine the majority of English ophthalmic surgeons were in the habit of administering an anæsthetic during the operation for extraction of cataract, unless they were able to assure themselves that they had the good fortune to deal with a calm, stoical, and non-spasmodic patient. The advent of the new local anæsthetic has in a great measure broken down our barrier of distrust, and by its aid we are now able to operate successfully on even the most nervous and sensitive of sufferers. But whilst we gratefully recognise the absence of pain which is secured by this valuable agent, we have become aware of certain inconveniencies which, unless duly guarded against, may seriously embarrass an inexperienced operator, and chief amongst these is the partial loss of control over the eyelids which follows on instillation of cocaine, so that the removal of the speculum either after or during an operation for cataract must be accomplished with great care, otherwise a violent spasmodic closure of the lids may produce disastrous results. I can also assure my professional brethren, from personal experience, for I have on more than one occasion kept a speculum in my eye for some minutes, that the forcible separation of the lids by our familiar wire coadjutor produces an almost uncontrollable tendency to squeeze them violently together, and there can be no doubt that the wings of the speculum afford a powerful leverage for the strong spasmodic effort which has so often ruptured a delicate hyaloid membrane and wrecked an otherwise promising operation.

I have therefore adopted a very simple method, which enables me to banish the speculum from all operations for cataract that are performed with cocaine. The chief desideratum is a well-trained and flexible ring-finger. That this digit is too often feeble and not properly under control, is a fact well recognised by pianists and other instrumental executants, and the special exercises that have been devised for its education might also be practised with advantage by ophthalmic surgeons. My plan of operating is as follows:—The eye is steadied with forceps held between the thumb and the two first fingers, whilst the ring-finger is used to elevate the upper lid to such an extent as will enable the operator to make the necessary section. The sensitive natural speculum possesses this great advantage—that it can recognise the commencement of a spasmodic effort on the part of the patient and at once give the necessary relaxation, and as the section is nearing its completion the gradual withdrawal of the finger allows the lids to close gently and without effort. If an iridectomy is to be made, the upper lid should be lightly raised at its edge, with the ring-finger of the left hand, whilst the iris is seized with suitable forceps held between the thumb and the first two fingers. It will thus be seen that the operator is able to dispense with the aid both of speculum and assistant. The above plan is so simple and, with a little practice, so easy of accomplishment, that it may very possibly have been already

[1] Read at the annual meeting of the Société Française d'Ophthalmologie, Paris, April 29th, 1886.

Digitized by Google



adopted; but as I have seen no mention of it, and as I have already operated by it successfully in a considerable number of cases both in private and at St. Mary's Hospital, I think it right to put my experiences on record. The cases where this method is most difficult of application are those in which the eyes are small and deeply seated, but a little extra patience and care on the part of the operator will surmount these obstacles; and, on the other hand, it is specially suitable for prominent eyes, where the use of the speculum has so often proved hazardous. The knife with which I operate differs somewhat in shape from Graefe's original pattern. It will be seen from Fig. 1 that the blade begins to broaden rapidly immediately below the point, which is central; the back of the knife is bevelled and the blade is rounded, so that in this respect it resembles the

FIG. 1.

Beer's knife, and does not permit a too rapid escape of aqueous. My knife is broader than those in general use; indeed, I understand that several of our foremost operators, both here and on the Continent, now prefer an extremely narrow blade. I have tried every variety of pattern, and have finally decided in favour of that which I have above described, because I find that it facilitates the accomplishment of a smooth and rapid section, and that the iris is less liable to fall in front of the edge of the knife than is the case with more attenuated blades. In making my section, I seize the subconjunctival tissue with forceps just below the spot where I intend to make my counter-puncture. I by no means follow the direction given in some of the text-books to make the puncture and counter-puncture exactly at the same level, because the adoption of that method

FIG. 2.

necessitates the immediate commencement of a sawing movement, which drags upon the globe, and must of necessity leave an objectionable serrated edge to the flap. I am careful to introduce my knife at a lower level than that at which the counter-puncture is to be made (*vide* Fig. 2). The moment that the point emerges, an upward and onward sliding movement imparted to the knife will enable three-fourths of the section to be smoothly completed before any backward motion need be employed, and the least possible amount of violence is thus done to the internal economy of the eye. After the capsule is ruptured, I gently depress the upper edge of the section to prevent it from impeding the exit of the cataract, and if the latter should refuse to quit its home after the exhibition of moderate pressure, I am frequently able to rotate it out by applying a curette to the margin of its under surface. These and other equally useful manœuvres are doubtless well known to all experienced ophthalmic surgeons, but I venture to hope that a trial will be made of the plan I have described, in which, in suitable cases, nature's speculum takes the place of that which we have hitherto used.

ON A NEW METHOD OF ESTIMATING THE CONDITION OF THE RIGHT SIDE OF THE HEART.

BY W. PASTEUR, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, AND MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

IN September, 1885, I called attention in the columns of THE LANCET to a distension of the superficial veins of the neck which occurs when, under certain circumstances, pressure is exerted over the liver. I have since then had the opportunity of examining a large number of patients presenting both positive and negative instances of this phenomenon, with results of sufficient interest to be worth recording. The physical sign in question is a distension or over-filling of the external jugular veins, apparently from below, with or without pulsation or undulation, which takes place when pressure is exerted in the right hypochondriac or epigastric regions with the flat of the hand, the direction of pressure being backwards and upwards. Before proceeding to make the examination the patient should be placed in the recumbent posture, with the neck slightly extended and the head turned a little to one side, while care is taken that the muscles of the neck are not in a state of tension. The sign is usually best marked on the right side, but may in almost every case be demonstrated on the left side also. It is essential that the movements of respiration should be normally maintained throughout the examination. I have frequently observed a partial filling-in of the supra-clavicular fossa at the moment when pressure is first exerted. This is especially marked in thin subjects, and may be accounted for to some extent, perhaps, by simple mechanical displacement, but is, I believe, chiefly due to an involuntary arrest or modification of breathing, and almost invariably subsides in a few moments. The amount of pressure required varies in different individuals. In rare cases rigidity of the abdominal muscles renders the manœuvre quite impossible. The presence of moderate ascites is no impediment, but excessive distension of the abdomen with fluid or gas renders the necessary manipulation more difficult and sometimes impossible. The pressure should be exercised gradually and steadily, otherwise an attack of coughing is liable to be induced, particularly in cases of bronchitis. The patients rarely complain of any pain or even discomfort, but on the occurrence of the least pain the manipulation should be at once discontinued. The following case affords a good illustration of the phenomenon.

L. W——, aged thirty, was admitted into the Middlesex Hospital in October, 1885, suffering from intense dyspnœa. The face was cyanosed, the lips very blue, and the breathing very rapid and shallow. There was moderate distension of the external jugular veins, which pulsated distinctly and filled from below. Over the heart's apex there was a short systolic bruit, with a line if conduction towards the axilla. The heart dulness was increased towards the right; the liver was not enlarged. Pressure exerted in the right hypochondriac and epigastric regions immediately produced a very marked alteration in the jugular veins. They became very visibly distended, the pulsation at the same time becoming less obvious, and shifting to a spot higher up the vein. This alteration in the condition of the veins persisted as long as the pressure was maintained, but on removing the hand these at once returned to their former state. The patient was treated with full doses of digitalis. On the third day there was a marked improvement in her general condition. The breathing had become natural and all trace of venous pulsation and distension had disappeared. Firm pressure applied as before was now entirely without effect on the veins. Once or twice a scarcely perceptible filling of them below the valves was observed, which was probably due to a slight modification in the breathing.

With a single exception, to which I shall refer again, this

Digitized by Google

phenomenon has invariably been met with in cases which showed evidence of great over-distension or failing compensation in the right heart. I believe it to be invariably present in well-marked tricuspid incompetence, whether functional or due to disease of the valves. Of this I have had post-mortem confirmation in at least four cases. But besides these there are a considerable number of cases which ultimately recover, in which the sign is present with varying intensity at one period or other of the illness. Such are instances of mitral valvular disease, whether regurgitant or stenotic, and of chronic pulmonary emphysema, complicated with acute or severe general bronchitis. The question naturally arises, whether the distension in these latter cases (emphysema, &c.) should be regarded as evidence of slight tricuspid incompetence or simply of great over-distension of the right heart falling short of failure of the tricuspid valve. It is to be noted that these are precisely the cases in which the question of tricuspid incompetence has to be considered from a prognostic point of view, and is often left undecided. Venous pulsation is generally absent, and often the cervical veins are but slightly distended. Not infrequently there is undulation at the spot where the distension of the vein ceases. This may be systolic only, or double, and synchronous with the heart beats. (I have hitherto failed to observe the quadruple undulations described by Guttmann.) The valves in the external jugular veins are usually competent, and the veins empty completely with each inspiration. The effect of pressure below the ribs varies in these cases with the amount of obstruction to the venous return. 1. In the least marked cases, the vein, although not perceptibly distending under the pressure, is seen, nevertheless, not to empty completely during inspiration. 2. In others a degree more severe, a moderate distension results; the vein becomes visible as far as the anterior border of the sterno-mastoid muscle, more rarely as high as the angle of the jaw. At the same time the spot where undulation was visible becomes shifted higher up the vein, and the character of the undulation is not infrequently modified, the double variety being replaced by a single systolic flicker, the single variety occasionally disappearing altogether. 3. In cases yet more severe, but in which the usual signs of tricuspid regurgitation are not developed, the pressure sign is often elicited with great distinctness, with or without undulation, and is, I think, here to be regarded as indicating early tricuspid failure. In the second class of cases, which differs from the third in degree only, I am inclined to think that there is great over-distension of the right heart, falling short, however, of regurgitation, possibly with excessive strain on the valve cusps.

The exception above mentioned occurred in a man who had a large empyema on the left side, with considerable displacement of the heart to the right. In this patient the sign was fairly well marked for a considerable time, but ultimately disappeared when he recovered, his heart having then returned to its normal position. I have entirely failed to obtain it in other cases of pleural effusion. The following case illustrates the information which may be conveyed by the absence of this sign.

H. W——, about fifty years of age, was admitted into the Middlesex Hospital in December, 1885, presenting the signs and symptoms of severe bronchitis and emphysema. The external jugular veins were distended, filling rapidly from below, but not pulsating visibly. Examination of the chest revealed nothing beyond marked emphysema and somewhat increased resistance, without dulness, over the upper two right interspaces near the sternum. There was slight bronchitis of the larger tubes. Beyond that mentioned there was no clear evidence of obstruction of veins within the thorax. Firm pressure below the ribs produced no change whatever in the external jugular veins. Relying on this evidence of the absence of tricuspid regurgitation, a diagnosis was hazarded of intra-thoracic growth obstructing the superior vena cava, which was completely verified at the post-mortem examination.

The mechanism of the production of this phenomenon is probably complex. Without presuming to offer a complete explanation, I would suggest that the following factors probably enter into it: 1. Compression of the inferior vena cava by the liver, especially in cases where this organ is enlarged. In my original communication considerable importance was attached to the *rôle* played by the enlarged liver in these cases. I am satisfied from observations in the post-mortem room that a certain amount of compression from this cause is possible. But looking at the nature of the cases in which this sign is met with, and in the face of the repeated observation that enlargement of the liver is not a *sine quâ non*, I am disposed to consider the conjunction casual rather than causal. This factor, however, probably acquires more importance in cases of tricuspid regurgitation, with pulsating liver. 2. Lessening of the inspiratory action of the thorax through interference with the movements of the diaphragm. This I believe to be a more important factor. It may be urged against it that, if true, pressure below the ribs should produce the same effect in healthy individuals. But I think it may fairly be argued that, whereas in health the heart and lungs may, and do almost immediately, adapt themselves to slight modifications of pressure, &c., within the thorax, it does not follow that in disease they possess the same capacity. 3. Direct mechanical interference with the proper movements of the right side of the heart. A glance at the anatomical relations of the right auricle and ventricle to the diaphragm and subjacent liver will suggest the possibility, not to say probability, of such interference.

There can be little doubt that the effect of subcostal pressure, whatever the mechanism of its action, is to put increased difficulties in the way of the proper action of the right side of the heart, so that the pressure sign in cases where the tricuspid value is considered to be still competent is to be looked upon as a measure of the capacity still possessed by the right heart to combat increased resistance. In cases where the tricuspid valve is incompetent, the effect of the pressure is to aggravate the conditions under which the heart is already unable to do its work, with a proportionate increase in the signs of that inability. I venture to think therefore that this subcostal pressure sign possesses undoubted value as a means of diagnosis, and may also afford valuable information as to the progress and ultimate prognosis of many cases in which we are now reduced to mere conjecture for want of some definite, tangible index of the condition and working power of the right side of the heart.

Queen-street, Mayfair, W.

ON THE NATURE OF WHOOPING-COUGH

WITH A DESCRIPTION OF A NEW MODE OF TREATMENT INTRODUCED BY PROFESSOR MONCORVO, OF RIO DE JANEIRO, AND ITS PRACTICAL RESULTS.

BY WILLIAM H. BARLOW, M.D.,

CONSULTING PHYSICIAN TO THE DISPENSARY, GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, MANCHESTER AND PENDLEBURY.

(*Continued from p. 871.*)

So much for the irritation and its seat; but what is the cause of that irritation? We all know the extreme sensitiveness of the parts about the entrance to the larynx, and a local irritant in that position being once granted, we have little difficulty in foretelling the train of symptoms that would be produced. But what is the local irritant, and how is it that the irritation is manifested in spasmodic paroxysms with intervals of repose? We shall endeavour to reply to these questions. We find the first trace of an idea that the cause of irritation might be parasitic, in a theory that it was due to the inhalation of the very minute eggs of some species of insect; but it was Rosen de Rosenstein[1] who, after studying with care the epidemics of this disease in Stockholm in 1743 and 1764, remarked that it only affects those who have never previously contracted it, and that it is not subject to return. He continues (I translate the substance): "One sees by this statement that the cause of the disease is the existence of a foreign matter or an injurious principle, which increases and propagates itself, like that of small-pox, among those who have not yet been attacked." He doubts whether we should attribute that cause to insects, but is quite sure that "the morbific principle insinuates itself partly into the chest by respiration and partly into the stomach, where the nerves are very numerous." Remarking that the irritation develops itself periodically with intervals of perfect repose, he goes on to say that "during that time the secretions accumulate, and, becoming abundant, provoke a new access, which, in its turn, terminates by the expulsion

[1] Dissertatio de Tussi (1742); and Traité des Mal. des Enf., trad. du Suédois par Le Febvre de Villebrune (Paris, 1778), p. 323.

Digitized by Google

of the agglomerated mucosities. The nature of the disease," says he, "at this period shows that we ought to destroy the principle in the place where it is seated; and it would be easy to destroy that principle if we knew of an appropriate specific." I have already alluded to the practice of Dr. Watson of Glasgow (see note 24), who applied to the interior of the larynx a solution of nitrate of silver, with, as Dr. West bears witness, sometimes very beneficial effects.

In the year 1867, Poulet,[2] in a communication to the Academy of Sciences of Paris, describes the result of certain researches into the organisms to be found in the respiration of children affected with whooping-cough. "The vapours of the respiration of the little patients," says he, "collected by the method described in my previous memoir, present on microscopic examination a real world of infusoria, in every case identical. The most numerous, which are also the smallest, may be referred to a species described by some under the name of 'monastermo,' and by others under that of 'bacterium termo.' Others, in very small numbers, move here and there on the field of the instrument. They have a rod-like (*bacillaire*) slightly spindle shape; their length is two or three hundredths of a millimetre; their width is scarcely half a hundredth of a millimetre. This is the species that Müller calls 'monaspunctum,' Ehremberg 'bodopunctum,' and that micrographists place among the bacteria, bacterium bacillus. Thus the whooping-cough, by these alterations of the expired air, takes a place in the class of infectious diseases, among which I have already studied, from the same point of view, small-pox, scarlatina, and typhoid fever." In 1870 our own fellow-citizen and honoured *confrère*, Dr. (now Professor) Arthur Ransome, brought before the Literary and Philosophical Society of Manchester a number of original researches upon the "Organic Matter in the Human Breath in Health and Disease,"[3] and "found in a case of measles and one of whooping-cough abundant specimens of a small round-celled conferva, like the penicillium glaucum." These results have also been confirmed, as regards measles, by Braidwood and Vacher. It is, however, since the publication in 1873 of the researches of Letzerich[4] that a clearer pathology has been developed. When we examine the sputum ejected after a typical spasm of whooping-cough, we find it to consist of two distinct parts: a clear, transparent, or semi-transparent glairy mucus, entangling roundish whitish-yellow spots, varying from the size of a millet-seed to that of a lentil. When these spots are submitted to microscopic inspection, they, says this eminent observer, are found to be composed of micrococci disposed in chains. Having submitted certain of these to culture, he found that at the end of five or six days the bacteria increased in volume, and became transformed into vesicles, holding in their interior a large number of spores. "These vesicles finally break up and set at liberty the spores, which afterwards become transformed into bacteria. The culture having been made in solution of starch or of sugar, there is seen the appearance of a mycelium, on which the spores attain their complete maturity. These last were round and of a dark colour." This observer introduced these spores into the tracheæ of different animals, who were each attacked at the end of a few days with laryngo-tracheal catarrh, and afterwards with spasmodic attacks of cough, with lassitude and want of appetite. On post-mortem examination, the writer found the same spores in the mucus of the larynx, the bronchi, and the pulmonary vesicles (*des alvéoles pulmonaires*). These studies of Letzerich aroused the attention of Dr. Henke,[5] who found by an extended examination of the sputa of children affected with whooping-cough that there were always present rounded cellules of from ten to twenty thousandths of a millimetre in diameter, with numerous nuclei and many spores endowed with the power of extensive movement. In simple bronchitis he could never discover any cryptogams such as those always found in whooping-cough, and he consequently considers them as the true cause of the disease. He observed also that the simple addition of a few drops of a solution of quinine to the preparation under the microscope caused the cessation of all movement among the spores. Tschamer de Gratz,[6] having never in numerous examinations found (except, in very rare cases, certain micrococci and bacteria, also observed in a state of health, and especially in the morning expectorations) anything comparable to these in cases of bronchitis, bronchiectasy, and pulmonary tubercle, set himself to examine the expectoration of a large number of children with whooping-cough, and he established the fact of the naked eye characteristics which I have before described. Further, he observed one or two days before the spasmodic or convulsive period, besides epithelial cells and a mycelium reticulated with polygonal meshes, round or ovoid spores, without colour, and variable in number and size. A little later these spores were found to be still further developed, for the most part round, and of a yellowish or even dark-red colour. He also cultivated these organisms in various ways, and introduced them into the tracheæ of hares, with results identical with those of Letzerich. He also found that these corpuscles were analogous to, if not identical with, those that are found in the depressions in the rinds of oranges and citrons in a state of putrefaction, in the form of a black velvety deposit. Carrying his researches to a further point than Letzerich, he abstained for fifteen days from seeing patients with whooping-cough, and carefully examined with the microscope the expectorations which he expelled, without ever finding anything analogous to what we have just described; and at the end of that time he began to inhale the black velvety matter found on the cortex of oranges, previously pulverised. On the *fourth day* he felt a pricking in the larynx which compelled him to cough, and *ten days later* the cough presented all the characters of whooping-cough. At the commencement of the fourteenth day he recognised the spores under the microscope, and the number from that time increased. Similar results also were observed in the case of another person who submitted himself to the same experiments. From these results this writer arrives at the conclusion that whooping-cough owes its origin to the presence of, and the irritation produced by, a cryptogamic parasite upon the mucous membrane of the larynx. The period of incubation he states to be the time necessary for the development and proliferation of those germs, and also to vary with the quantity introduced into the respiratory passages. From the irritation and inflammation caused by their presence on the laryngeal mucous membrane result the primordial phenomena, which precede the period of convulsive cough. He explains the periodicity of the attacks by the necessity that must exist for the effects of the irritation to accumulate before it can produce that reflex action. When the germs are in small number, the constant and abundant expectoration may carry away these cryptogams in numbers exceeding those of their formation, and thus may account for those cases of spontaneous cure which are not unfrequently seen in whooping-cough.

These conclusions, it is but fair to say, have been denied by Professor Rossbach, of Würtzburg,[7] who states that laryngoscopic examination has always shown to him the pharynx, the larynx, and the upper part of the trachea perfectly sound, and without any trace of inflammation. He acknowledges the presence in the broncho-laryngeal secretions of spores and of mycelium, but he says identical with what one observes in ordinary catarrh. But these negative conclusions have not been confirmed by other observers; thus, Meyer Hüm,[8] who made numerous examinations with the laryngoscope in cases of whooping-cough, has always seen inflammation of the pharyngo-laryngeal mucous membrane. Oltramare, of Geneva,[9] comes to the same conclusions as Tschamer as the result of his independent researches. Among many others also, the commentators on the work of the late Professor Steiner, of Prague, have shown themselves fully in accord with the results of the researches of Letzerich and Tschamer. Lastly, Dr. Burger, of Bonn,[10] has supported by new facts the parasitic doctrine of whooping-cough. This author describes a bacillus which he has found in the expectorations of this disease in considerable numbers, and which may be observed with an enlargement of ½ Zeiss. So examined, they are seen under the form of little rods (*bâtonnets*) of variable dimensions, the smallest of them being twice as long as they are wide. When examined by the aid of the apparatus of Abbé, we may easily see that the longest of them present a central constriction, making them resemble somewhat the form of an hour-glass. They were

Digitized by Google

disposed sometimes in chains, sometimes at regular intervals, and again in the form of irregular masses. Coloured with aniline, they showed themselves with remarkable distinctness. They should not, according to the writer, be confounded with the Leptotrix-buccalis, since the spores of the latter, besides their larger size, are accompanied by filaments peculiar to them. From these facts Burger deduces a bond of connexion between these germs and whooping-cough—"first, because one never meets them in any other kind of expectoration; secondly, because they exist in such considerable amount that one cannot doubt their morbific action; thirdly, from the relation that exists between the abundance of the spores and the intensity of the disease."

At this point the inquiry was taken up by Professor Moncorvo, of the Polyclinique, Rio de Janeiro. This gentleman, aided by Professor Silva Araujo, of the same institution, made many microscopic examinations of the matters expectorated, sometimes in the catarrhal and sometimes in the spasmodic stage of whooping-cough; not only in those who had never been treated medicinally, but also in those under treatment and in progress of cure. "In the expectoration rejected immediately before the examination," says this writer,[11] "we discovered a great quantity of little yellowish masses, irregularly rounded, of a size about that of a pin's head, immersed in mucus. These are found in greatest abundance in the expectoration of those children in whom the disease has attained an advanced period of spasmodic cough. When submitted to microscopic examination, without the addition of any reagent or of any colouring matter, we have observed what we are about to describe as the *résumé* of different examinations. We have found pavement epithelial cells, polyhedric, irregular, and provided with a nucleus, globules of pus, more or less numerous small globules (globulins), and a considerable quantity of micrococci; all these elements were immersed in an amorphous matter, strongly glutinous, which constitutes the gangue of that magma. The epithelium cells show themselves under different sizes and diverse forms, and were all provided with a nucleus, and were of a double contour. What we saw of the greatest interest was the infiltration with spores, infinitely small and brilliant, of veritable micrococci, which existed in profusion in the interior of the cells, always keeping the same disposition as in the amorphous substance which surrounded them—that is to say, the disposition in linear series, in chains or chaplets, or in groups, which vary from two, three, four, or more; or, finally, they were isolated and distinct one from another, although close together, on account of their considerable number. That profusion, so that the chains formed by the micrococci crossed each other in different directions under the field of the microscope, became much more marked when the preparation was coloured with picro-carmine or violet of methyl. In all the rest of the preparation the micrococci showed themselves in extraordinary abundance, forming in different points true zoogloea or groups of spores agglomerated by an amorphous unitive matter. The globules of pus were equally filled and infiltrated with micrococci. This element, which predominated in considerable quantity in preparations made with expectoration ejected during the convulsive period of the cough, diminished and became less abundant in those made with the products of expectoration during the latter stages of the disease, principally at an epoch near to that of the favourable termination. They were also in very small numbers in the examinations practised in the catarrhal stage. At the same sitting we have been able to observe the relative proportion between these elements at two different periods of the cough, by examining one after the other the matters expectorated by two children affected with whooping-cough, dating in one case from eight days, and in the other from twenty days. Those of the first, in which the spasmodic phenomena were still vague, contained a number much inferior when compared with that in the second preparation, in which the epithelium cells were extraordinarily infiltrated with spores, and a prodigious number encumbered the field of the preparation. Examined with the naked eye, the matters ejected by the first did not show, as did the second, any great number of the yellowish corpuscles, which were described by Tschamer de Gratz; but we have not met, as did that observer, with mycelium which for the rest we have seen in great abundance in the black powdery matter which develops on the rind of an orange in full putrefaction." He then goes on to say that he has never seen the little rods with central hour-glass construction described by Burger de Bonn, and suggests that he has mistaken chains of spores united two to two in such a manner as to simulate a central constriction for these. "In a great number of our preparations the micrococci were endowed with movement, except when they were made with the expectoration of infants already submitted to the topical application of resorcine. The presence and the proliferation of the micrococci in proportion to the advance of the whooping, and, on the other hand, their diminution and the loss of their movement towards the termination of the attack under the direct influence of treatment, appears to me to constitute indices the most significant of the causal relation between the parasite developed upon the laryngeal mucous membrane and the disease." Even Prof. Rosshach, who was supposed to have contested the parasitic origin of this disease, regards the expectorations as of a nature probably virulent, without explaining in any way the reason of that supposed virulence.

(To be concluded.)

NOTES ON THE CLINICAL VALUE OF THE BACILLUS TUBERCULOSIS.

BY ALEXANDER BLACK, M.B., F.R.C.P. EDIN.

THE experience of the last few years among practitioners as to the value of the presence of the bacillus in the sputum of phthisical patients is varied: some declaring that it is to be detected in almost every case, at least at some period of the history of the disease; others that they have seen it disappear before death; and others, again, arguing against its importance as a factor in diagnosis from its spasmodic occurrence. From an examination of numerous cases, it would seem to me to have a clinical value far beyond what it has hitherto had as an element in diagnosis. The method of detection I have invariably employed has been that of Gibbes, and of this method it can only be said that it has always given uniform results. In every case error in observation was prevented by preparing duplicates. In several cases of undoubted phthisis repeated examination has not discovered any trace of the bacillus, while in other more doubtful cases the finding of the bacillus has at once added certainty to the diagnosis. In the cases of undoubted phthisis where the sputum has been examined and bacilli found wanting, it has been found that the symptoms as apart from the local signs of the disease have been extremely slight, and certainly some of the characteristic symptoms of the disease have been entirely absent—as, for example, the anæmia and night sweats.

In the case of one sputum from a woman aged about forty, who in early years had been the subject of glandular abscesses of the neck, and who at present is suffering from a catarrhal affection of both lungs, as evidenced by the local signs, there has not hitherto been found a single bacillus. This patient complains of nothing save the cough, expectoration, and great debility. An examination of the lungs reveals crackling indeterminate breath sounds over the front of both lungs, with marked impairment of the percussion note at the upper part of the right lung. The patient has no night sweats, and has a remarkably healthy ruddy colour. Her lips are rosy red, as also the interior of the mouth; and the conjunctivæ have their normal appearance. One of this patient's children, aged six, died some short time ago from tubercular disease of the lung, and another, aged eighteen months, died from meningitis. What appears to me the feature of this case is the apparently grave nature of the local signs, and the absence of general symptoms commensurate with the local disease. This, also in connexion with the absence of bacilli in the sputum, is further remarkable.

Another case is that of a man, aged thirty-two, who had a slight pulmonary hæmorrhage. He had formerly been in good health; only one illness can he remember, and that was pleurisy, when he was a lad. For some short time before the hæmorrhage he had not felt well, complaining of

Digitized by Google

cough, emaciation, and general debility. What struck me first of all, on seeing this patient, was his extreme pallor, notwithstanding the small amount of hæmorrhage that had occurred—certainly not more than two tablespoonfuls of blood. His gums, palate, and conjunctivæ had the appearance of extreme anæmia. On physical examination the right side of the thorax was found to expand much less freely than the left side. This may have been the result of the old pleurisy, as it had occurred on this side. Percussion revealed a note of higher pitch and shorter duration at the outer part of the base of the right lung. The vocal resonance was much increased here, and the other auscultatory sounds were a loud apparently friction sound and moist râles. The other parts of the lungs seemed perfectly free from disease. The patient also complained of pain at what I considered the seat of the disease. As has been mentioned above, for some short time before the hæmorrhage he had complained of losing flesh, night sweats, and general debility. An examination of the sputum was made as soon as it was untinged with blood, and the examination revealed numerous bacilli. Here, then, was a case the chief feature of which was the extreme anæmia, emaciation, and night sweats, associated with comparatively slight local signs and coincident with the presence of numerous bacilli in the sputum.

One other case deserves mention, that of a young man, a watchmaker by trade, who came to me several months ago complaining of pain in the left side, cough, and expectoration. On examination, a friction sound was heard about the middle of the left side at the seat of the pain; crackling was also present; but there was at this time no impairment of the percussion note. The man gradually from this time became emaciated and anæmic, night sweats and extreme debility being also present. A few days after, the above local signs continuing, there was superadded to them a very marked impairment of the percussion note. The patient continued going on from bad to worse, and it was determined to send him off to some country town (Peebles), where he could at least have the advantage of fresh air and milk. Unfortunately, at this time his sputum was not examined. While in the country he gradually improved, gained flesh, and got rid of the night sweats. Several weeks' residence in the country improved him so much that he determined to return to town and resume work. On examining him on his return, the left side was found to be even worse than on his removal to the country, showing that, at any rate, the physical signs had not improved. The percussion note over the whole side, back, and front was much impaired, it giving the impression that the underlying lung was almost solid. At the upper part of the lung tubular breathing, without moist râle accompanying it, was heard, and at the middle and lower parts of the lung crackling indeterminate respiration. His sputum at this time showed entire absence of bacilli, and what seems remarkable was that the man complained of nothing save his cough. I regret that this man's sputum was not examined before his removal to the country, as I should have expected to have found numerous bacilli. At any rate, the absence of bacilli and of general symptoms on his return is sufficiently striking.

I think most of us who have examined the sputum for bacilli will admit to having seen a general improvement in the patient coincident with a diminution in the number of bacilli. Why this should be it is easy enough to imagine, if they have a causal relation to tubercular disease. It appears to me to be an explanation accounting for the grave symptoms of phthisis pulmonalis apart from the local signs, if we imagine the bacilli to be the origin of some product which, on admission to the blood system, acts as a poison either on the nervous centres, causing vaso-motor and other disturbances, or perhaps acts directly on the blood itself, destroying its hæmoglobin (pre-tubercular anæmia). At any rate, there seems reason to believe in the following assertions:—1. That in those cases of phthisis pulmonalis with grave constitutional symptoms, unaccompanied by local signs or commensurate local signs sufficient of themselves to account for the symptoms, the chances are that the bacilli are present in greater or less quantity. 2. That in those cases where the constitutional symptoms are slight and the apparent local signs great, the chances are that the bacilli are more or less absent. 3. That the first effect of the diminution of the number of bacilli in the sputum will be an amelioration of the general disturbance. Our aim, then, should be directed towards the destruction of the bacilli when present, and preventing them doveloping when the soil is suitable.

I have not spoken of temperature, as my observations are not yet ample enough to draw any conclusion therefrom.

Edinburgh.

SEQUEL TO A CASE OF MYXŒDEMA IN A WOMAN AGED SEVENTY-SIX.

BY C. W. SUCKLING, M.D. LOND., M.R.C.P.

IN THE LANCET last year I published an account of a case of myxœdema in a woman aged seventy-six. Since then the patient remained in the Birmingham Workhouse Infirmary *in statû quo* until Feb. 26th last, when my attention was drawn to her. I found that she was semi-comatose, could not speak or be made to respond in any way to questions put to her. The pulse was 36 per minute, and very feeble; the respiration 16, stertorous; the temperature was 95°. On the 27th the patient was completely comatose. The pulse was still 36; the respirations 12 per minute. The temperature could not be taken with the ordinary clinical thermometers, which were not graduated below 95°, the mercury not rising to within an inch of the first mark on the glass. A thermometer used for taking the temperature of baths was separated from its iron frame, on which was the graduation, and the bulb was placed under the tongue for half an hour, the level of the mercury being marked on the stem with ink. The thermometer was again placed in its frame, and the registration was 76·5°. The next day the pulse was imperceptible at the wrist, the heart-beats being 20 per minute. The temperature, taken the same way as the day before, was 70°. During the day it was taken several times, and varied from 66° to 70°. The patient died the same night. The bath thermometer, immersed in warm water, at the end of three minutes registered 99°, a clinical thermometer 98·5°, so that we must not conclude that the patient's temperature was exactly as recorded. Still, allowing a degree or two, the temperature in this case must be one of the lowest ever recorded during life. Dr. Barling, Professor of Pathology at the Queen's College, has kindly undertaken to report a full account of the necropsy.

Birmingham.

THE CONNEXION BETWEEN GLYCOSURIA AND BILIARY OBSTRUCTION.

BY W. T. WYATT, M.A., M.D. OXON.

IT has been demonstrated by Dr. Wickam Legg, and confirmed by Von Wittich, that ligature of the bile-ducts causes the disappearance of glycogen from the liver, and that after ligature glycosuria cannot be produced by puncture of the floor of the fourth ventricle or section of the cervical sympathetic. It is presumed that the retention of bile within the liver interferes with the nutrition of the hepatic cells, and so prevents them from carrying on their natural function of glycogen formation.

The following clinical case appears to me to support the conclusions drawn from the above-mentioned experiment. A lady, aged sixty, has for some time suffered from glycosuria, and latterly albumen has been present in addition; the amount of sugar excreted usually ranges from ten to twelve grains per ounce, and no material alteration in this quantity occurred when the urine became albuminous. The urine has been always highly saccharine, even when a strictly nitrogenous diet was enforced, a symptom pointing to the fact that a too rapid metamorphosis of hepatic glycogen was the probable source of the excess of sugar in this case. A short while ago this patient became jaundiced, the urine containing both biliary acids and colouring matters, and with the appearance of the jaundice the sugar diminished from its usual amount to a hardly perceptible trace, Fehling's reagent, the picric acid and indigo carmine tests, giving almost negative results. The disappearance of the sugar could in no way be accounted for by alterations in diet, for the appetite and manner of living remained the same as usual. In this case, however, there was undoubtedly

Digitized by Google

some obstruction to the bile-ducts, as no bile could be detected passing with the stools, so that a pathological condition was here established analogous in its result to the experimental ligature, for in each case the escape of bile was effectually hindered. If, then, it is correct that the retention of bile within the liver prevents the formation of hepatic glycogen, it necessarily follows that the same retention must greatly diminish the amount of sugar in a case of glycosuria of that type in which the disease is chiefly dependent on a too rapid metamorphosis of glycogen into sugar. In making deductions from a single case, it is well-nigh impossible to separate the *post hoc* from the *propter hoc;* but, at any rate, in this case, coincident with the retention of bile, the amount of sugar excreted fell to zero, and remained so as long as the obstruction lasted—speedily, however, regaining its usual amount of ten grains per ounce as soon as bile was again poured into the intestines.

The whole subject of glycosuria up till now has been elucidated more by the experimental physiologist than by the physician. However valuable such experiments may be, the results obtained from them are often very fallacious, the condition under which they are conducted in many cases being far removed from anything existing in nature, so that confirmation of such observations by clinical work is always highly satisfactory. Of course the phenomena of this case may bear an interpretation differing widely from that which I have assigned to them; still, I venture to think that the biliary retention being accompanied by an almost entire absence of sugar in the urine was not a mere coincidence, but that the two symptoms were related to each other as cause and effect.

Stamford-hill.

CASE OF SUPPURATING KIDNEY; NEPHROTOMY AND DRAINAGE.

BY MICHAEL T. SADLER, M.D. LOND., &c.,
HONORARY PHYSICIAN TO THE BECKETT HOSPITAL, BARNSLEY.

E. N——, aged twenty-two, telegraph clerk, consulted me for the first time on Jan. 18th, 1885, on account of a pain in his right side. He had been ailing for about two years, and had felt more or less of the pain for about twelve months. Since November, 1884, he had lost weight and strength rather rapidly, but had not left his work. Sometimes the pain was very violent, striking up into his head and face in the form of neuralgia. There were also frequent night sweats. The pulse was usually 110 to 120, and the temperature, even in the morning, over 100°. On examination, I found a tumour, which he had not noticed, in the right flank, rounded, ill-defined, semi-fluctuating, extending from the liver down within the crest of the ilium, coming in front to within two inches of the umbilicus, and passing backwards behind the dorsal muscles. The urine, on examination, proved to be albuminous, containing much pus; sp. gr. 1014. At times the urine was for a short time clear and free from pus or albumen. There was no distinct phthisical family history. His father and one sister died of heart disease.

Having arranged for his admission into a private ward in the Beckett Hospital, on March 6th I cut down on the kidney by an incision four inches long one inch below and parallel with the last rib on the right side. On dividing the lumbar fascia about a pint of offensive curdy pus escaped, and then the finger could be passed into a cavity roughly reniform in shape, occupying the position of the tumour, apparently about eight or nine inches from above downwards, but the lower end of which could not be reached. No calculus could be felt. The cavity was washed out with carbolic lotion, and a large drainage-tube inserted.

The pain ceased to be troublesome after the operation, the hectic symptoms gradually diminished, and the appetite, which had been very poor, soon returned. The drainage-tube was kept in until the 21st, the cavity being daily washed out with carbolic lotion until the 24th, when the urine became smoky-looking, and sanitas was substituted for carbolic acid in the lotion. On April 6th he was allowed to leave his bed, and on the 19th was removed home. On the 20th he passed a small phosphatic calculus by the urethra, and on May 9th had suddenly an attack of pain in the left calf and foot, with partial obstruction of the left femoral artery. This, however, had quite passed off by the 20th, and from that time his progress, though slow, was continuous, although the urine continued to contain pus, sometimes more and sometimes less. In July he returned to his work and was able to attend the regulation number of hours (eight daily) until March, 1886. Up to Christmas, 1885, he was free from pain, had a tolerable appetite, taking more milk than meat, and had gained flesh. There was still a discharge of pus from the opening in the loin, but the urine was free from any cloudiness. A sample examined on Nov. 11th proved, however, to be albuminous, sp. gr. 1014, alkaline, with a white deposit containing pus-cells and a few crystals of triple phosphate. He broke down under the severe weather of February and March, 1886, and died from uræmia on March 19th. No examination of the body was obtained.

ABSCESS OF KIDNEY TREATED BY FREQUENT TAPPINGS; RECOVERY.

BY THOMAS EDWARDS, M.R.C.S., L.R.C.P., L.M.

ON Dec. 4th, 1885, W. V——, aged twenty-three, of this village, working in London as a gravedigger, returned home complaining of constant pain of a dull aching character in the lumbar region, which he had had for the last eighteen months. He had been treated for lumbago and liver disease. The family history is good. He stated that he had never injured himself to his knowledge, and that he had "shivering fits" continually.

On examination the patient was greatly emaciated, appearing as one in the last stage of phthisis. There was pain on pressure over the right kidney, also pain on fully extending the right leg. There appeared to me deep fluctuation midway between the last rib and the crest of the ilium. Hectic fever and rigors were present; the urine was scanty and high-coloured, albuminous, but free from blood or pus; there was also profuse diarrhœa. I inserted obliquely upwards a trocar and cannula (one I usually carry in my dressing-case) to its full length, midway between the last rib and the crest of the ilium and two inches from the spine, and drew off a tumblerful of offensive pus resembling cream.

For the following two days the patient's condition improved, but soon afterwards all the bad symptoms returned. I again tapped and drew off another half-pint of pus. I repeated this operation five times, drawing off altogether three pints and a half of pus, the last drawn being terribly offensive. On each occasion the small wound made by the trocar healed in a day or two. The patient's condition after this greatly improved; the pain, fever, and rigors disappeared; he could walk, had a good appetite, and was rapidly gaining flesh. I gave quinine throughout, but now added tincture of iron and cod-liver oil. About three weeks after the last tapping the patient complained of an uncomfortable feeling in the old place, but no pain. I again tapped, and drew off three pints of clear amber-coloured fluid resembling urine; this operation I repeated several times, but on each occasion less came away, until it disappeared. The patient has quite regained his health and strength, taking long walks daily. Urine normal.

Harrold, Beds.

LIVERPOOL SOUTHERN HOSPITAL.—On the 11th inst. the Duke of Connaught, who accompanied Her Majesty in her recent visit to Liverpool, visited this hospital, which fourteen years ago he had formally opened. An address was presented to the distinguished visitor, in which it was stated that since its opening 107,000 persons had received at it medical or surgical aid. After inspecting the various wards, the Duke gave the name of the "Margaret Ward" to the apartment occupied by the children, and expressed his great satisfaction with the arrangement and management of the institution.

IN St. Pancras on Sunday last, the fourth annual United Friendly Societies' demonstration and church parade in aid of the funds of the West London and University College Hospitals took place, in the presence of a large number of persons. Collection boxes were exhibited along the route taken by the procession, and a substantial sum is said to have been collected.

ST. GEORGE'S HOSPITAL.

A CASE OF OVARIAN DERMOID TUMOUR IN A GIRL OF THIRTEEN; ROTATION AND COMMENCING GANGRENE OF THE CYST; OVARIOTOMY; RECOVERY; REMARKS.

(Under the care of Dr. CAVAFY and Mr. HAWARD.)

THE following case is one which presents several points of interest: the age of the patient, the character of the tumour, and the twisting of the pedicle, which had produced several attacks of localised peritonitis, from changes in the cyst wall, due to obstructed circulation, and had even caused commencing gangrene at the time of removal. We would refer our readers to the remarks appended to the case. The inflammation of the parotids, which developed six days after operation, does not appear to have been severe, or accompanied by much pain or constitutional disturbance. It may possibly be an example of the parotitis which occasionally develops after abdominal operations, though that is usually limited to one gland, rarely if ever affecting both simultaneously.

Alice A——, thirteen years and nine months of age, was admitted on June 6th, 1885, on account of constipation, vomiting, and abdominal pain. The mother stated that she had for some months past noticed the girl's abdomen to be swollen, and that the child had on three or four occasions during the last four months complained of stomach-ache and sickness; but these symptoms were not severe, and passed off without treatment, so that she attributed no importance to them. Menstruation had not commenced. During the last week in May a more severe attack of abdominal pain occurred, and though it ceased after a few hours the child had not seemed well since, but had been languid and lacked appetite. On June 3rd the abdominal pain recurred with severity, the child became worse, and lay in bed with her knees drawn up. On the following day vomiting occurred, and continued several times every day, chiefly after food. The matter vomited was said to have become offensive. There had been no action of the bowels since June 2nd. Some aperient had been given, but was vomited. Enemata had also been administered, but brought away only a few very small lumps of feculent material.

Her condition on admission, described chiefly from notes by Dr. Griffiths, the registrar, was as follows:—She was a pale girl of fair growth. Pulse 84, very small and weak; temperature 100°. Examination of the abdomen revealed an elastic tumour of rounded outline, extending downwards from about an inch above the umbilicus, and three or four inches towards each iliac fossa. It was more prominent on the left of the umbilicus, but extended rather further to the right of the middle line. The tumour was elastic, dull to percussion, and movable. Beyond the tumour the abdomen was mostly resonant, though there was slight comparative dulness in the right flank. She was given belladonna and opium, and small quantities of beef-tea and milk.

On June 7th, Dr. Cavafy, having diagnosed the case as one of ovarian tumour, requested Mr. Haward to see the child in consultation. She had not been sick, and was in rather less pain. Temperature 100°; pulse 120, weak. She lay sometimes on her back, sometimes on her side, with the knees drawn up; tongue slightly coated. There had been no action of the bowels. A catheter was passed into the bladder, and a small quantity of urine drawn off; it was high-coloured, had a specific gravity of 1028, and was free from albumen. Examination of the rectum showed the bowel to be empty as far as the finger reached. The uterus could be felt of natural size and position. The tumour was also easily felt through the bowel. There was some abdominal tenderness, chiefly over and in the neighbourhood of the tumour. There was very little resistance of the abdominal muscles. Mr. Haward agreed with Dr. Cavafy's diagnosis of ovarian tumour, which had probably recently risen out of the pelvis.

On June 8th there was more abdominal pain and tenderness. The tumour was now more prominent, especially towards the right side of the umbilicus. Pulse 120, weak. Rather more distension of abdomen; no action of bowels; she looked decidedly more ill. Dr. Champneys now saw the case in consultation, and agreed that the tumour was an ovarian cyst, and that peritonitis was commencing, probably in consequence of a twist of the pedicle. Ovariotomy was decided upon, and was performed next morning by Mr. Haward. Ether was administered and antiseptic precautions observed, but no spray was used. An incision was made in the middle line below the umbilicus, and on opening the peritoneal cavity a considerable quantity of clear light-yellow fluid escaped. The peritoneum was vividly injected. The tumour at once presented, and was seen to be of dark-purple colour, its vessels greatly congested, and some parts of the surface almost black. The cyst was thick-walled, about eight or ten inches in diameter, and very tense. It was tapped and emptied of its fluid, which contained a large quantity of blood. The pedicle was seen to be twisted twice round its vertical axis. The cyst having been drawn out of the wound, the pedicle was transfixed and tied with a double ligature of carbolised silk; the tumour was then cut away and the pedicle returned into the abdomen. The left ovary was ascertained to be healthy. The wound was closed with deep and superficial sutures of carbolised silk and covered with a dry pad of carbolised wool enclosed in eucalyptus gauze, over which strips of plaster and a flannel bandage were applied. The tumour sprang from the right ovary, and within the chief cyst was a smaller one containing caseous matter and hair.

No sickness followed the operation, but the bowels acted several times, the motions being very loose. She was given five drops of laudanum in a teaspoonful of water every four hours. No food was given till the following day, when she was allowed a pint of milk in the twenty-four hours. She went on well, with a natural temperature, till June 13th, when a sudden rise of temperature occurred (102·6°). The wound was therefore dressed, when it was found that she had passed some urine in bed, and that the bandage and pad under her back had thus become soiled. The wound was united soundly, excepting that a little pus had formed round the two lowest superficial sutures. All the stitches were removed. The temperature from this date declined, and on the 16th was normal, after which there was no further rise. On the 14th she had complained of tenderness at the angles of the jaw, and on the 15th both parotid glands were tender and swollen. The attack of mumps, however, soon passed, and from that time she made an uninterrupted recovery. At the end of a fortnight she was well, and after a few days was allowed to get up. On July 15th she was sent to the Convalescent Hospital at Wimbledon.

Remarks.—Mr. Haward, after pointing out the grounds of the diagnosis, said that the surgical treatment was obviously ovariotomy; for the history of the previous attacks of pain, the subsidence of these, and the sudden recurrence of pain and vomiting pointed almost certainly to a rotation of the tumour, with the attendant dangers—hæmorrhage, gangrene of the cyst, and peritonitis. It seemed more probable that the constipation depended upon peritonitis than upon obstruction of the bowel by the pedicle or the tumour, because of the subsidence of the vomiting and the slight amount of distension of the abdomen. The operation was performed with every antiseptic precaution, although the spray was not used, Mr. Haward stating that he had found his ovarian operations were no exception to the rule that obtained with regard to his other operation—namely, that, provided due care were observed in other respects, nothing was gained by the use of the spray. The dressings consisted of a dry antiseptic pad, which was recommended both for comfort and efficiency, not only for abdominal section, but for most recent wounds. Wet dressings are much more apt to irritate the skin and to excite suppuration; dry antiseptic wool, on the other hand, absorbs discharge, protects the wound from external influences, maintains the part at an equable temperature, and by its elasticity gives comfortable support and keeps the wound at rest. The after-treatment was of the simplest kind. No food was given for the first sixteen hours, thirst being allayed by washing out the mouth with warm water in which a little permanganate of potash was dissolved. Small doses of laudanum were

Digitized by Google

given at first because of the looseness of the bowels, and later on, when the urine became loaded, lithia water was ordered. This was all that was needed in the way of medicine. The transient fever which occurred after the operation was probably due to the attack of mumps, which did not, however, materially delay recovery. The importance of examining both ovaries at the time of operation was pointed out and illustrated by the relation of two other cases of ovariotomy in quite young women, in whom Mr. Haward had found both ovaries diseased to an extent requiring removal. The first, a girl of eighteen, had, like the present case, a dermoid cyst of the right ovary; the diagnosis of its character being easy from the fact that hard masses (bone and teeth) could be felt in the cyst through the rectum. This cyst being removed, the other ovary was examined, and found to contain several cysts, one of which was of the size of the fist; it was therefore also excised. The second patient, aged twenty, had a large cyst of each ovary, forming tumours of about equal size. They were both removed. The patients in each instance made rapid and uninterrupted recoveries. The child whose case is related above has quite recently been to report herself at the hospital, and is in perfect health.

BURTON-ON-TRENT INFIRMARY.

A CASE OF "CRUSHED ABDOMEN"; DEATH ON THE THIRD DAY; NECROPSY; REMARKS.

(Under the care of Mr. MASON.)

DAVID T——, aged thirty-three, a porter, was admitted early on April 16th. He walked from the cab into the ward. He complained of great pain in the epigastrium, and said he had been squeezed between the buffers of two trucks, which were wide enough apart for him to get through sideways, but that steam was put on at the moment, and he had been caught and held some seconds. He had been seen and released at once. He had not been unconscious.

On admission the extremities were cold. There was no pulse at the wrist. The body was warm and without marks of violence. No ribs were broken. The heart-beat was regular—100, rather feeble. No abnormal dulness on percussion. The epigastrium was very tender on pressure. No hæmoptysis, hæmatemesis, or melæna. He had passed urine just previously to the accident. Vomits a good deal of greenish bile. He was ordered nutrient enemata every two hours, and nothing but ice by mouth. A soap-and-water enema brought away a healthy motion, but no blood.

April 17th.—Much the same. No pulse. Vomits a great deal of bile; is in great pain. Enemata continued and retained well.

18th.—Seems better to-day. Less pain and no vomiting. Called for food, and was allowed some beef-tea, which he retained some hours and afterwards vomited. Pulse at wrist for first time about 100, regular, small.

19th.—Pulse absent at wrist; hands cold. Sat up in bed twice to-day, once of his own accord, the second time at the request to have his back examined. Some dulness at left base behind. Dulness for two inches below right nipple; resonant below and over front of abdomen; rather dull in flanks; abdomen swollen. Died at 12 noon.

Necropsy.—On opening the abdomen a most fetid smell arose, and a large quantity of fluid blood poured out. The omentum was adherent all over to the intestines, which were likewise glued together by recent lymph. The coils of small intestine lying below the umbilicus were quite black, and had lost their gloss in places. The intestine was ruptured transversely in three places, to the extent of an inch, at a distance of a few inches from one another and about four feet from the cæcum. The liver, which was uninjured, was pushed upwards, and had its lower edge pointing forwards just at the level of the right nipple (hence the dulness), its ordinary position being occupied by distended gut. The stomach, kidneys, and spleen were healthy. The lungs were rather collapsed, especially the left, which was displaced upwards considerably by the blood in the abdomen, corresponding with the dulness observed at the left base behind.

Remarks by Mr. MASON.—The case is remarkable for the length of time the man lived with such extensive injuries, and with such an absence of symptoms, especially that there was no discharge of blood from either the mouth or bowel. I saw him about half an hour before his death, when he was complaining of the nurses because they would not bring him any solid food. After this he fell asleep, and died in his sleep.

WEST BROMWICH DISTRICT HOSPITAL.

A CASE OF RARE INJURY TO THE PELVIS; DEATH; NECROPSY.

(Under the care of Mr. LANGLEY BROWNE.)

THE following notes have been furnished by Mr. E. W. D. Kite, house-surgeon.

E. H.——, aged twenty-six, a powerfully built man, was admitted on Dec. 13th, 1885, in a state of extreme collapse. He had been raising a grindstone weighing nearly two tons, when the crane chain slipped and he was knocked down, the grindstone falling on his left hip and remaining there for some minutes before it could be removed. The left limb was colder than the right; there was pulsation in both tibials; no signs of fracture; swelling above Poupart's ligament extending along the iliac crest; very little bruising; a small wound in the perineum a little to the right of the raphé. When a catheter was passed into the bladder, bloody fluid rose and fell with the respirations, but no urine passed.

There being evidently ruptured bladder, it was resolved to open and clean the abdomen, to stitch up the bladder and drain; but before doing this the perineal wound was enlarged so as to admit an exploring finger. A tremendous gush of clots then took place, followed by very free hæmorrhage. An incision was then made above Poupart's ligament, and the swelling found to consist of blood-clot. The external iliac was then exposed by pushing up the peritoneum, and it was then seen that the epigastric artery was torn off from the external iliac, leaving a hole in the side of the latter, from which the hæmorrhage arose. A ligature was passed above and below the aperture, and all hæmorrhage ceased. The patient died in four hours from shock. After death it was found that both rami of the pubis were fractured obliquely, and that they had been greatly displaced under pressure, returning to their normal position when the pressure was taken off. The upper fractured ramus had torn off the epigastric and had lacerated the bladder; the lower one had torn across the urethra and inflicted the perineal wound. As all the injuries were extra-peritoneal, a long drainage-tube was passed from the iliac incision through the perineal wound, the course which the blood had taken after rising along the crest of the ilium. In this case abdominal section would have been of no use.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. W. VINCENT JACKSON.)

THE following is chiefly remarkable as being the record of surgical work done in a single day by one surgeon in a provincial hospital.

CASE 1. *Perineal Median Cystotomy for the removal of a small Vesical Calculus.*—E. H. J——, aged five years, was admitted with a small stone in the bladder. Chloroform being administered, a small-sized staff grooved on the convexity was passed into the bladder. A small incision half an inch long was made in the median line of the perineum, the urethra being incised at the same time. Along the groove of the staff a director was conducted into the bladder, and the former being withdrawn, a very narrow pair of lithotomy forceps was pushed within the groove of the latter into the bladder; the director being then removed, the stone was caught and brought away; it weighed 26 gr.

CASE 2. *Amputation of the Tongue.*—J. B——, aged eighty-two, was admitted with epithelial cancer of the right side of the tongue far back. Chloroform was administered, and the whole of the tongue was cut away.

CASE 3. *Amputation of a portion of the Tongue for Tubercular Ulceration of the Lip.*—Rachel L——, aged thirty-seven, was admitted by Dr. Malet on account of a very painful ulcer, the size of a sixpence, at the tip of the tongue, and with signs of advanced phthisis at the apices of both lungs. Chloroform was administered, and the front portion of the tongue, half an inch from the apex, was cut away with scissors. Afterwards the mucous membrane covering the two surfaces was brought together by ten points of interrupted suture of very fine silk.

Digitized by Google

CASE 4. *Ligature of Brachial Artery.*—W. B——, aged thirty-three, was admitted on account of an aneurysm of the left radial artery high up, as well as extensive disease of the aortic valves. The left brachial artery was ligatured in the middle of its course.

CASE 5. *Amputation of the Right Leg.*—D. C——, aged forty-six, was admitted with a large epithelial ulcer of the outer side of the right foot. An ulcer had existed for thirty-four years. Ether was administered, and amputation of the upper third of the right leg was performed.

CASE 6. *Trephining the Upper End of the Left Tibia.*—Annie W——, aged thirteen, was admitted on account of constant pain at the upper end of the tibia, which was enlarged, and the periosteum covering it thickened. Chloroform was administered, and the painful spot was deeply trephined.

CASE 7. *Osteotomy of both Tibiæ.*—Sarah G——, aged three, was sent in by Dr. Dingley on account of right genu valgum and considerable anterior curvature of both tibiæ. Chloroform was administered, Esmarch's bandage applied, and each tibia having been sawn across and the fibulæ broken, the limbs were adjusted into a straight position upon proper splints.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Ligature of the Larger Arteries in their Continuity.—Congenital Absence of Hair with Atrophy of Skin and its Appendages.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. BALLANCE and Mr. W. EDMUNDS communicated a paper on the Ligature of the Larger Arteries in their Continuity: an Experimental Inquiry. The experiments were made by the permission of Professor Birch-Hirschfeld at Leipzig. The object of the paper was to show that in the ligature of a large artery in its continuity (1) it was neither necessary nor advisable to tie the ligature so tightly as to rupture the coats of the vessel; (2) the lumen of the vessel must be completely or almost completely obliterated; (3) the round ligature, of small size and possessed of certain qualities, was the best. The authors commenced with a short historical sketch. They then stated the reasons which led them to perform the experiments which formed the basis of the paper. Nineteen carotid arteries of sheep and horses were ligatured, some with catgut and others with kangaroo tendon, and the result in each case was given. The animals were killed and the vessels removed from nine hours to seventy-three days after ligature. The general results of the operations were summarised, and the best material for ligature and the function of the clot discussed. Certain objections which might be raised were considered, and, in conclusion, the authors recommended for the operation of ligation in continuity—(1) aseptic precautions; (2) the small round absorbable ligature; (3) the maintenance of the integrity of the arterial wall. The paper was illustrated by macroscopic and microscopic preparations, and by drawings. It was seen in the preparations that the inner coats, even where included in the ligature, were alive and apparently of unimpaired vitality; that, although the tunics were unruptured, a plastic effusion had taken place, which in the arteries removed latest was developing into connective tissue, permanently occluding the vessel. With respect to the ligatures, leucocytes were thrown out round them, and gradually caused their absorption. In the case of kangaroo tendon, the absorption took place only from the surface; but with catgut the leucocytes insinuated themselves along the crevices formed by the twisting of the gut, and the ligature became absorbed more rapidly. The durability of catgut seemed to vary in different specimens; but it was thought that in wounds that healed by first intention good catgut held for about a month, and kangaroo tendon for two. In the three carotids of horses in which alone suppuration had occurred, it was proved that catgut was rapidly becoming absorbed in fourteen days, and had completely disappeared in fifty-one days, and that kangaroo tendon was but little altered in ten days.—Mr. BARWELL agreed largely with the conclusions of the authors, especially as to the undesirability of rupturing the internal coats. Whether it was preferable to use the round rather than the flat ligature for the purpose was a matter on which he joined issue with them. A small round ligature would more readily tear the inner coat. We ought not to lose sight of the different states in which the vessels are; some were tightly stretched, and others in a lax state. He had formed his own conclusions as the results of experiments on dead subjects and living animals. He considered that a flat ligature could lie smoothly, and the knot was not clumsy, though of large size, which he regarded as an advantage, for a small knot of catgut was more liable to set up ulceration and perforation, as in a case of innominate aneurysm in which Mr. Bennett May ligatured the carotid artery. A large knot obviated that difficulty of ulceration and perforation altogether. Again, a small knot was not sufficiently broad to resist the impulse of the blood current. A good-sized clot in the vessel was also advantageous as a check to the force of the blood current. There was further a general unreliability in carbolised catgut, which at least introduced an element of undesirable uncertainty, for it might be absorbed in a very short time.—Mr. SCOVELL SAVORY considered that the authors had collected an interesting series of facts, but he could hardly follow them in their conclusions that it was neither necessary nor advisable to rupture the inner coats. He failed to see how their experiments proved that it was not advisable; they had made no "check" experiments; their paper abounded in *ex parte* statements; the experiments had all been done in one way. If check experiments had been made they might have had facts which would justify their conclusions. Experimental investigations tended to show that the arterial system of animals differed very much from that of man; it was much more difficult to excite septic processes in animals, as Dr. Jones long ago proved. It was owing to the greater number of mishaps where animal ligatures were employed that made many surgeons hesitate still to employ them in preference to silk ligatures.—Mr. T. HOLMES also congratulated the authors on their industry and on the interest of the facts collated in the paper; but he hesitated to accept their main conclusions. He would not like to trust experiments on animals in guiding him as to what to do in the human subject. In one of Mr. Barwell's cases of ligature without rupture of the internal coats the vessel became pervious not long after the operation. He had been content with the practice at St. George's of division of the internal coats. In one instance Mr. Pick ligatured the femoral for popliteal aneurysm without rupturing the internal tunics, and pulsation recurred, though he felt bound to add that the vessel was afterwards tied lower down as tightly as possible, and then pulsation recurred. In truth, a long period of experience on human subjects would be necessary before we could accept the conclusions of the authors. In division of the internal tunics a greater amount of lymph was thrown out, which in itself would appear to be an advantage, and he asked whether there was a corresponding disadvantage in this excess of lymph. He could not but think that experiments on animals were not entirely satisfactory. It was at one time thought that a powerful barrier to the restoration of the circulation would be found in the employment of silver ligatures, which would produce no irritation. But in one instance in the practice of Brodhurst secondary hæmorrhage occurred. In a paper read before the Pathological Society Mr. Pick also showed how the artery could be occluded without dividing the internal coats by ligatures, which at the end of three weeks had not caused ulceration.—Mr. C. DENT had been engaged in a similar inquiry on the femoral arteries of sheep, using kangaroo tendon prepared in chromic acid, the internal tunics being completely ruptured. He considered that rupture of the tunics made the operation certain and was a better surgical practice. In one case pus formed around the ligature, which had not been rendered sufficiently aseptic. In none of the cases did secondary hæmorrhage occur.—Mr. BARWELL explained that he used the ox aorta ligature in the case referred to by Mr. Holmes, and the failure was purely an error of manipulation, and had nothing to do with the nature of the material employed.—Mr. W. EDMUNDS, in reply, pointed out that even in tying a flat ligature the knot was liable to present an angular projection, and so Mr. Barwell's argument that with a flat ligature the adhesion between the coats was

Digitized by Google

favoured need not always hold good.—Mr. BALLANCE, in reply, admitted that more skill was necessary to apply a round ligature so as not to rupture the internal coats, but a very little practice in the post-mortem room would suffice to show how to occlude the lumen of the vessel, so that no water could be syringed through. On examination it would be found that no damage to the tunics had been done. A long piece of artery was occluded even with a small ligature, as the specimens on the table showed. Dr. Jones's classical work was referred to by Mr. Savory, but at that time it was thought that the question of rupture of the coats had been threshed out. His object and that of Mr. Edmunds was to present a series of observations showing what happened when the coats were not ruptured.

Mr. JONATHAN HUTCHINSON contributed a paper on a case of Congenital Absence of Hair, with Atrophic Condition of the Skin and its Appendages, in a boy whose mother had been almost wholly bald from alopecia areata from the age of six. This paper described the case of a boy three years and a half old, who presented a very withered "old-manish" appearance. His skin was remarkably thin, in some places being not thicker than brown paper. The genitals presented a marked contrast to the rest of the body, being in the state of a normally plump child. He had no nipples, their sites being occupied by little patches of scar. The history of the patient showed that it had been necessary to turn during delivery, but he had had no ailments since teething. He was liable to vary much in blueness from temperature or excitement. The question of heredity in this case was discussed.—Mr. W. SEDGWICK said that the subject of hereditary alopecia was illustrated by Dr. Thurnam many years ago in a paper read before the Society. The grandmother and two grandsons had well-marked alopecia, and the teeth numbered only four in the grandchildren; the microscope showed an atrophic condition of sweat ducts and glands. Sometimes this atrophy was associated with a great development of hair in other members of the family. Among birds, by breeding in-and-in alopecia could be developed. The "top-knotted" variety of canary could also be obtained, and if two such bred together their offspring were frequently bald on the top of the head, and in some cases a deficiency of the skin also occurred.—Mr. J. HUTCHINSON had not described the case as simply one of congenital alopecia. The skin was defective in development also, and the nipples were absent, whilst, strangely enough, there was a perfect development of the skin of the genitals. There was an *acquired* defect in the mother, and a congenital defect in the child; but it would be futile to discuss the possible relationship until further facts had been brought together.

OPHTHALMOLOGICAL SOCIETY.

Exophthalmic Goitre.

AT an ordinary meeting of this Society held on May 6th, Mr. Jonathan Hutchinson, F.R.S., President in the chair, several papers were read on Graves' disease.

Mr. JONATHAN HUTCHINSON opened the discussion and dealt chiefly with the prognosis and treatment. In one case of complete recovery that occurred in a medical man, and which was recorded by Dr. Warburton Begbie in his collected works as recently published by the New Sydenham Society, the disease was in full course ten years ago. The pulse was very frequent, as much as 140 per minute. There was albuminuria for one year. The individual, though very nervous, was now in excellent health. There was, however, an intermittent pulse, the carotids pulsated, and the thyroid was still slightly enlarged; palpitation, too, was easily brought on and the pulse easily accelerated. A variety of remedies had been used, and a sea voyage taken, but it was difficult to say which remedy had done most good. The man himself believed that the bromide of potassium in twenty-grain doses three times a day had most effect in controlling the disease. But aconite, digitalis, and iron were also employed. Mr. Hutchinson related another case in which the coincidence of albuminuria also obtained. (Dr. W. Begbie had first prominently brought forward the occurrence of albuminuria.) It was that of a clergyman, and almost exactly parallel to that of the medical man. Both patients had been also examined by Dr. George Johnson. There was albuminuria every day for a year at least, but it was present on some parts of the day only, after meals, and more after breakfast than at any other time: after 3 P.M. it was usually absent. The extreme uncertainty of the prognosis of the disease, which was sometimes so threatening and prolonged, was referred to. He then said that his own experience was necessarily fragmentary, most of the cases being brought to him for ocular symptoms. He had seen a considerable number improve under the use of such remedies as digitalis, aconite, iron, and bromide of potassium. In one case a medical man pushed the tincture of aconite till twenty minims three or four times a day were given, and the good result was ascribed to that. As to the treatment of the ocular symptom, Mr. Hutchinson spoke very favourably of the systematic application of cold to the temples and forehead by means of ice bladders, and also to the nape of the neck. He had never seen the eyes lost in any case under his own care, though he knew of cases that had become completely blind. With regard to the influence of disturbed sexual and menstrual function, it was to be noted that young women and young men were attacked in preference to those of more advanced age. It was said never to happen to those who were pregnant. He believed that the disturbance of sexual functions must be regarded as the result of a common cause. He could not agree with the statement of Niemeyer that if men were affected with the malady they were of advanced age; his experience was to the contrary. He narrated an interesting case in which there was loss of sight of both eyes due to ulceration of the cornea, with sequent opacity. The patient was a woman aged twenty-five, who had been twice married; the proptosis began in the fifth month of pregnancy and lasted sixteen months. She had the affection for twelve months whilst suckling and for four months whilst pregnant. She did not suffer much in general health, and the case was an exception to the rule that pregnant women never suffer. If males were affected, he did not agree with Niemeyer that the disease was more likely to be more severe and fatal. His youngest case was in a boy and the two oldest were women.

Dr. BRISTOWE explained that he had no statistics to give, but that he proposed merely to place before the Society a group of interesting cases, which were already (when the announcement of the discussion was made) written out for publication, together with two or three additional facts furnished by other cases. He first gave very brief details of a recent case, in which, in a woman aged forty, the symptoms of Graves' disease were distinctly referable to prolonged exposure to cold. He also mentioned one case in which recovery appeared to be complete; and another in which, all signs of proptosis and enlarged thyroid having subsided, the patient still suffered at times from severe palpitation. He referred also to a case of the disease in which exophthalmos was associated with syphilis; and to one in which the patient died from organic heart disease. The cases of chief interest were three in number. Of these, the first was that (which had already appeared in *Brain*) of a young woman, who, about the year 1877, first showed signs of proptosis, enlarged thyroid, and palpitation, which symptoms, after continuing for a few years, became complicated with those of ophthalmoplegia externa. In 1882 she came under Dr. Bristowe's care. She was then suffering from nearly complete paralysis of all the external ocular muscles, ptosis, and proptosis. Moreover, she had complete hemianæsthesia on the right side, with colour-blindness and loss of taste and smell on the same side. Later, fits, apparently epileptic, supervened, with rigid paralysis of the right arm and leg. Also, she suffered from hæmorrhage from the ears. She was under Dr. Bristowe's care for two years, who, not at the time knowing she had suffered from Graves' disease, attributed her proptosis to weakness of the paralysed eye muscles. The thyroid was not visibly enlarged. She had no palpitation, but her temperature from first to last varied daily between 100° and 103°, 104°, or 105°. Finally, she died of an acute attack of bronchitis. At the necropsy no disease was discovered in the nervous centres; the thyroid was a little larger than normal; there was much fat in the orbit, and the ocular muscles were pale. Excepting for the prominence of the eyeballs, the patient appeared, so far as the signs of Graves' disease are concerned, to have recovered. The second case was that of a young married woman who had suffered for three or four years from Graves' disease, and in which the thyroid had become so large as latterly to cause attacks of severe dyspnœa. It was on this account that she went into the hospital. Her breathing was stridulous; but no

Digitized by Google

immediate danger being anticipated, no operative procedure was contemplated at the time. Unfortunately, a day or two after admission, she was attacked with a severe paroxysm of dyspnœa and, before anything could be done to relieve her, died. The third case was that of a young woman who had been suffering from the usual symptoms for some years, but who was also the subject of serious organic heart disease, there being evidence of aortic, mitral, and tricuspid affection. On admission, her breathing was stridulous; and, having regard to the result of the case last narrated, Dr. Bristowe consulted with his colleague, Mr. Sydney Jones, as to whether any operation was feasible. The goitre was unusually large, but fortunately the isthmus was narrow, and it was consequently determined to remove a portion of the isthmus and dissever the two lateral lobes—an operation which Mr. Jones had performed with admirable results in a case of ordinary goitre of Dr. Bristowe's, in which suffocation threatened. The operation was successfully completed in this case, and was followed by dwindling of the lateral lobes of the thyroid body and cessation of stridor. No other definite improvement followed. The prominence of the eyeballs continued, and the cardiac symptoms unfortunately progressed unfavourably, so that at the end of about four months the patient died of the heart disease.

A paper by Dr. Wilks was read by the Secretary (Dr. Sharkey). Dr. Wilks stated that, of the many cases which he had seen, some had recovered, others had died, and others had been lost sight of. He had also seen slight cases, which were probably modifications of the complaint. As to the question, What were the characteristic symptoms? he considered that there were increased frequency of the heart's action, enlarged thyroid, prominent eyeballs, a loud murmur heard in the veins with a thrill, and, in severe cases, great emaciation, with outbursts of sweating and diarrhœa. The increase in the cardiac rapidity he regarded as a primary and necessary symptom; quickened cardiac action, combined with exophthalmos and emaciation, or with enlarged thyroid and emaciation, he would regard as characteristic. The theory which attributed the symptoms to disease of the sympathetic in the neck was not good, and had not been found true in fact; though there was, probably, some disturbance of the sympathetic, giving rise to the extreme relaxation of the bloodvessels; the relaxation gave rise to murmurs which were much larger and harsher than any met with in simple anæmia; the diarrhœa and sweating might also be due to the sympathetic disturbance. Apart from the proptosis and enlarged thyroid, which could not come on suddenly, the symptoms resembled those seen in nervous women, especially at the climacteric. Violent palpitation, clammy sweat, diarrhœa, starting eyes, and choking were the symptoms produced by sudden fright. It was therefore reasonable to look to some relaxation of the sympathetic as a cause of the combination of symptoms seen in Graves' disease. The disease also seemed to have some relations with anæmia and chlorosis. Belladonna was the only drug in which he felt any confidence; he had observed the symptoms, even in severe progressive cases, so speedily reduced, that he could not doubt the value of the drug. After using it for some weeks, it was his custom, as the cases were tedious, to substitute iron, iodide of potassium, or digitalis, but he had observed no good effect attributable to these drugs. He gave the following categorical replies to the series of questions circulated by the Society (see THE LANCET, March 20th, p. 548.) 1. He had performed one necropsy; no lesion was found in the nerves or elsewhere. 2. No cause could be assigned in any case. 3. He had seen several cases in young women where the symptoms were modified. 4. He thought the disease removable (or curable). 5. He had had cases under treatment for two or three years, with great improvement; but relapses occurred. 6. He had never seen a case recover without treatment. 7. In none of his cases had the eye become diseased or vision imperfect. 8. He had never seen a case of simple exophthalmos. 12. He had never seen Graves' disease in conjunction with others (but he referred to Dr. Carrington's case mentioned below). 13. He had only seen two males affected with the disease; they were aged twenty-four and twenty-six respectively. He thought the disease was in some way associated with the reproductive organs; in women, he had seen it generally in those of middle age with families, or in young girls with anæmia and amenorrhœa.

Dr. HUGHLINGS JACKSON attached great importance to Graefe's sign, but had seen well marked cases of Graves' disease in which it was absent, mentioning, in illustration, the cases of two sisters. Again, he had found the sign present in a man who had no Graves' disease. These observations had been confirmed by Mr. Couper. Referring to the cases of the two sisters above mentioned, Dr. Hughlings Jackson remarked that a third sister was said to have the same morbid affection. Dr. Cheadle had seen four cases of Graves' disease in one family. Dr. Hughlings Jackson suggested a comparative study of such cases with some other "family diseases," such as pseudo-hypertrophic paralysis, Freidreich's disease, &c. In all the recent (eight) cases of Graves' disease he had seen, the right lobe of the thyroid was the larger, a fact bearing on the question as to central pathology, as Dr. W. A. Fitzgerald had suggested. The right vagus had, in some lower animals, more inhibitory influence on the heart than the left. Dr. Hughlings Jackson thought the hypothesis of a central pathology the most probable, and, in this connexion, referred to the experiments of Brown-Séquard and Filhene on production of exophthalmos by injuries of the restiform body. He believed that most would be learned as to the seat of changes in Graves' disease, from experiments on lower animals. In all cases of fatal Graves' disease, the medulla oblongata and pons Varolii should be carefully searched microscopically. He referred to so-called complicated cases, mentioning the remarkable case recorded by Dr. Warner and Dr. Bristowe, in which there was ophthalmoplegia externa; and a like case he had seen, a case complicated with asthmatic paroxysms, one with paroxysms of right-sided facial spasms, unlike cortical facial spasm, and a variety he supposed to depend on discharge of facial centres in the pons Varolii. Dr. Pavy had noted the association of Graves' disease with diabetes. In the so-called complicated cases the association might be accidental, but Dr. Hughlings Jackson thought they deserved very careful consideration. He did not remember seeing a case of Graves' disease in a man.

Dr. FITZGERALD (Dublin) said he had never yet seen the visible pulsation of the arteria centralis retina described by de Wecker. Visible pulsation of the veins was very frequently seen. Graefe's sign was not constantly present. In the cases in which a perfect cure occurred some of the ordinary symptoms were absent, or little marked. In some cases only one eye was affected by proptosis. He had seen one well-marked case in a man at the Meath Hospital, under the care of Mr. Foote, a man aged twenty-eight, in whom the affection had come on after an occasion on which he had danced excessively.

Mr. HILL GRIFFITH read a paper on thirty cases of Graves' disease. Twenty-seven were females and three males. The symptoms commenced twice under the age of twenty, sixteen times between twenty and thirty, seven times between thirty and forty, and five times between forty and fifty. Eighteen were single and twelve married. The ocular symptoms were bilateral twenty-three times, the right eye alone affected four times, the left three. Retraction of the upper lid (Stellwag's sign) was present twenty-two times, in four of which the lower lids were also retracted, it was absent three times, and not noted five times. Graefe's sign—a loss of consensual downward movement of the upper lid—was present four times, absent four times, and not noted twenty-two times. There was bilateral goitre fifteen times, and in three of these it was more marked on the right side, and there was increased pulsation of the carotid arteries. Spontaneous arterial pulsation was looked for in every case, and its absence was noted in twenty-six; there were no notes in this connexion of the remaining four. There were acute gastric symptoms at the commencement of the disease twelve times, loss of flesh twice, and minor complaints six times; no illness ten times. As to nervous symptoms, one patient felt as if she would choke sometimes, and then had a distinct hysterical attack; a third was easily frightened; and every morning a fourth was of "fussy" behaviour, and two others often flushed. Mr. Griffith thought the agitation of the patients was very characteristic. There were hæmic murmurs three times, an aortic systolic three times, mitral systolic the same number, and and in two a "thrill" was noted in the swelling; aortic regurgitation once. The right lobe was alone enlarged in two cases; goitre was absent in thirteen cases. Vision was normal seventeen times, subnormal twelve times, and once not noted. Of the twelve subnormal, ten were due to astigmatism; high degrees of myopia with staphyloma posticum. In two there was an amblyopia, and both improved. The refraction was normal twenty-two times, high degree of hypermetropia once, myopia four times, and

Digitized by Google

astigmatism three times. The fundus was normal in twenty-six cases, and abnormal in four; two with monocular myopia and staphyloma posticum, the eye symptoms being symmetrical; "cork-screw" veins were noted once, and once a glistening striated patch at the upper and outer part of one disc. The remainder were probably normal. Glycosuria was observed twice. The menopause began three years before the symptoms in one instance; in another the patient had severe headaches at the periods; and in another the catamenia ceased for six months, dating from the ocular symptoms; twice the catamenia were noted as irregular. As to the order of occurrence of goitre and exophthalmia in the seventeen cases in which both symptoms were present, in three the goitre preceded by two years, one year, and six months respectively; in one the symptoms were synchronous; in another the patient noticed the exophthalmos first. Frequently the patients were not aware of the presence of the goitre.

Dr. SAMUEL WEST read a paper on thirty-eight cases of exophthalmic goitre. About one case in every 1000 out-patients represented, perhaps, the relative frequency of the disease. Two-thirds of the cases occurred before the age of thirty. There were three male cases in a total of fifty-one. The ocular, thyroid, and cardiac symptoms all appeared simultaneously in six cases; the thyroid enlargement occurred first in eight cases; palpitation appeared alone and first in nine cases; exophthalmos came first and alone in four cases. From these and other facts, it seemed that there was great irregularity in the relative time of appearance of the cardinal symptoms. The right lobe of the thyroid was larger than the left, where there was a difference between the two. In one case, a marked decrease in size of the thyroid occurred after an acute attack of pneumonia. Exophthalmos appeared generally to be a late symptom. Graefe's sign was noted only in seven cases. Graefe's statement that the pupils were never dilated was not absolutely true. In one case there was slight ptosis of both eyes; in another there was persistent crossed diplopia and an external squint of the left eye. Attacks of profuse sweating were noticed in four cases. Seven times uncontrollable and unaccountable diarrhœa was observed, and six times paroxysms of vomiting. Diabetes mellitus was present in one case. A bronzing of the skin, suggestive of Addison's disease, was remarked in one case. Inexplicable changes in bodily temperature were recorded seven times; twice there was remarkable pyrexia, recalling that met with in cerebro-spinal disease. Other nervous symptoms noted in some cases were change in manner and character, somnambulism, trembling, fits, megrim, neuralgia, insanity, chorea. In eight cases there was a definite history of rheumatic fever. Considering the rarity of exophthalmic goitre, it was remarkable that rheumatic fever should be so often associated with it; possibly, the severe organic valvular disease noted sometimes may be due to antecedent rheumatic fever. Overwork, severe parturition, blows, fits, and rheumatic fever were causes assigned in a few cases; in the majority no cause was given. No constant relation could be established between the disease and the catamenia. In some cases there was a family history of nervous diseases. The longest duration of the disease was nine years, the shortest two months. In three fatal cases the disease had lasted respectively four years, two years, and three months. The constant application of cold seemed to have undoubted influence for good in the treatment of some cases.

Mr. C. HIGGENS related the case of a woman, aged twenty-nine, in whom the exophthalmos was so extreme that it appeared desirable to attempt to partially unite the margins of the lids; the patient died under the influence of an anæsthetic. The case was fully recorded in the Transactions of the Pathological Society, vol. xxv., p. 240. The main points noted at the necropsy (by Dr. Goodhart) were enlargement of the thyroid gland and thyroid veins, and slight hypertrophy of the heart; thickening of the sympathetic capsule, and of the mediastinal and cervical connective tissue; growth of gland tissue in the region of the thymus, and tendency of the lymphatic glands elsewhere to enlarge.

Dr. CARRINGTON narrated a case of exophthalmic goitre associated with Addison's disease in a woman aged twenty-three. There was a family history of phthisis, and she had suffered from migraine. The symptoms were palpitation and prominent eyes for two years, with vomiting and a feeling of great weakness and exhaustion. For eight months the catamenia had not been regular; there was frequent epistaxis, but no emaciation. The bronzing of the skin was most marked about the eyelids, neck, abdomen, umbilicus, and flexor aspects of the forearms and hams. There was extreme exophthalmos; Graefe's sign was well marked; but she had no paralysis, and no affection of the optic disc or vision. The pupils were widely dilated, and scarcely acted to light or in accommodation. The right lobe of the thyroid was the larger. There were loud murmurs over the heart and in the jugular veins, but the heart was not enlarged, and the pulse was very small and feeble. He had seen three fatal cases; two had acute enteritis, and the third mitral regurgitation.

Mr. FREDERICK MASON spoke of the case of a woman aged thirty-five, in whom the eyeball was dislocated from between the eyelids by any disturbance of the eyelids; sometimes in the same case there was spontaneous dislocation.

Dr. SILCOCK described the necropsy of the case of a female, aged thirty, who died from uræmic poisoning. He found nothing abnormal in the nervous system. The muscles were in a state of fatty degeneration or rather infiltration, as the microscope showed. The cranial nerves and sympathetic ganglia were normal. The thyroid gland was enlarged, and the right lobe the larger. The interstitial connective tissue was increased, and there was overgrowth of the acinal epithelium. Dr. Cheadle had described in one case increased vascularity of the medulla and pons. Electrolysis appeared to have been of value in the treatment.

Mr. LANG read an epitome of six cases observed by Dr. J. J. Pringle and himself, in which unilateral lid phenomenon without proptosis was associated with no other evidence of Graves' disease, except slight thyroid enlargement in two of the cases. In four of these paresis of orbital muscles was present, and in three sensory phenomena (pain, scalding lacrymation, &c.) In none was there cardiac disease or disorder, nor had they ever noticed implication of the lower lid. They were inclined to consider their observations as lending support to the theory of the central origin of Graves' disease, and to regard a tonic contraction of the levator palpebræ superioris as the immediate cause of the lid phenomenon, in opposition to the well-known views of Graefe.

Mr. W. H. JESSOP said that when the eye was brought under the influence of cocaine, the palpebral aperture was widened, and distinct proptosis produced. By dropping cocaine into the eye, in a case of Graves' disease, he had intensified the exophthalmos, and made Graefe's symptom more marked.

OBSTETRICAL SOCIETY OF LONDON.

Elasticity, Retraction, and Polarity of the Uterus.—Serous Perimetritis.

A MEETING of this Society was held on May 5th, Dr. Potter, President, in the chair.

Dr. SAMUEL SLOAN (Glasgow) showed Graduated Uterine Dilators and also Graduated Dilators for the Female Urethra.

Dr. J. MATTHEWS DUNCAN read a paper on Elasticity, Retraction, and Polarity of the Uterus. Retractility has been defined as that property of the uterine tissue in virtue of which the womb emptied of a part, or of the whole, of its contents, acquires a greater thickness of wall at the same time that its volume and its capacity are diminished. It is a function of muscular tissue, and it gets only a little supplementary aid from elasticity. The elasticity of each of the three layers of the uterine wall was discussed, as it exists in healthy and in morbid conditions. Retraction is not merely a condition, it is a force. During pregnancy it is a mere tonic tightening. In labour its action is necessary. In labour there is inhibition of it in the circular fibres of the lower segment of the uterus, and in the whole cervix and vagina. Retraction implies expulsion of contents; but the retraction is not necessarily in proportion to the advance of contents. There is probably an essential difference between contraction and retraction. Each may go on without the other. The usual comparisons of the action of the uterus and of the heart were criticised, and a new comparison suggested between the whole of pregnancy and a diastole, and the whole of labour and a systole. The expulsion of a fibroid was cited in corroboration and illustration. Cases of morbid retraction and of morbid absence of retraction were mentioned. Ergot causes retraction and not contraction, and hence its failures, its injuries, and its benefits. John Williams describes the retraction of menstruation. Uterine polarity, described by Reil, and redescribed by Champneys, was referred to, and illustrations of its action given.—Dr.

Digitized by Google

GALABIN agreed with almost the whole of the author's description of retraction of the uterus. He was surprised to see it stated, however, that ergot produced only retraction, and not contraction. If this were so, then the general opinion that in some cases ergot acts as an oxytocic and hastens delivery or completes it when nature cannot must be wrong. Rupture of the uterus occurs in some cases of obstructed labour after the use of ergot, intense rhythmical pains having preceded the rupture. In such cases he did not think rupture could be accounted for by continuous tension and pressure due to retraction having weakened the vitality of the tissue. Perhaps the explanation was that Dr. Duncan refused the title of contraction to that kind of contraction which was the initial stage of retraction. Such a use of the words could not be maintained. By contraction he understood shortening and thickening of the muscular fibres; by retraction, a similar shortening and thickening, not followed by relaxation and lengthening, but leaving a permanent shrinking after the tension of the contraction had passed off. Retraction was contraction and something more. The contraction itself was identical in the two cases. Thus in post-partum hæmorrhage the contraction was the same whether it was followed by relaxation and renewal of hæmorrhage or ended in retraction and arrest of hæmorrhage. He believed that ergot had the power of intensifying both effects in variable degrees in different cases—both the initial rhythmical contraction and the subsequently persisting tonic contraction which maintained the shrinking produced by it.—Dr. HORROCKS said elasticity of muscular fibre, though nearly perfect, is not sufficient in amount to diminish the size of the uterus after labour; with removal of the stretching force muscular fibre regains its normal size. Retraction means contraction not followed by relaxation. A contracted muscle feels hard, a retracted one does not. Retraction after parturition is probably due to the absence of sufficient force inside the cavity to stretch the fibres to their former length. Polarity of the uterus is merely a part of the great general question of relaxation of opponent muscles. He illustrated this by reference to various groups of muscles; relaxation of the fibres of the cervix during the contraction of those of the fundus is merely one example of the general law. He then discussed reflex tone of muscles, and pointed out that in defecation, micturition, and parturition there is a reflex tonic contraction kept up in the muscular fibres, especially in the sphincters. The contraction of the sphincters can be inhibited, and the nerve-centres for inhibition are closely associated with those for contraction. Defecation, micturition, and parturition can take place independently of volition, or even of consciousness. The will has, however, a modified power over them, and can help to start them. Finally, ergot will cause contraction of muscular fibre, because it has been given successfully many times to bring on premature labour.—Dr. CHAMPNEYS had difficulty in accepting the teaching that ergot produced retraction. He did not believe that it produced true contraction, neither did he believe that it produced true retraction. Ergot often produced a contraction of limited extent, and then tetanus, the organ contracting and then remaining of the same size, but hard and rigid. This was rather tonic contraction than retraction. With regard to polarity, the action of opponents referred to by Dr. Horrocks was exemplified in the uterus by conditions involving a disturbance of the normal condition, in which consentaneous, though opposite, action was observed in the upper and lower poles, such as incarceration of the placenta after pains and some forms of dysmenorrhœa, conditions analogous to colic in other hollow muscular viscera, the pain being due to violent opposition instead of normal yielding of one muscle to another.—Dr. SLOAN (Glasgow) thought it must be admitted that retraction differed from contraction, for after the uterus was quite emptied we found in the intervals of the pains free from tonic contraction the uterus smaller—i.e., retracted. He thought morphia was the exact opponent of ergot in its action on the lower segment of the uterus. It caused inhibition of this segment, and thus accelerated dilatation. He suggested that great mental distress, as in unmarried women, by preventing healthy retraction, favoured absorption and puerperal fever.—Dr. BROWN said that light might be thrown on the question as to whether ergot caused retraction or contraction by noting its action in small doses in threatened abortion, or in preventing habitual abortion. In the former its use stops the uterine contractions if not too far advanced, and in the latter the habitual tendency can be cured. On the principle of the double action of medicines, these facts may elucidate the point at issue.—Dr. ROPER remarked on the difficulty of separating contraction from retraction. Retraction could not occur without antecedent contraction. At the end of a contraction of a uterine muscular fibre there was no return to the original state or to relaxation, as in a voluntary muscular fibre. The first effect of ergot was to cause contraction; then followed traction, according to the potency of its stimulation. Ergot interrupted the rhythm and caused tonic spasm both in the body and cervix. It seemed questionable whether it directly stimulated the fibres of the cervix or whether it interrupted their inhibition.—Dr. PERIGAL remarked that ergot seemed to expend its action on the lower segment and affect the fundus but little.—Dr. DUNCAN, in reply, said he could not recognise in ergot the power to induce labour or abortion except in an indirect and uncertain way. It was common to hear of great pains induced by ergot, but he had not met with them. We much wanted a medicine which had that power; it was a want not yet supplied.

Dr. AMAND ROUTH related a case of Serous Perimetritis. The disease was brought on by a chill during menstruation, in a woman aged twenty-seven, suffering from subinvolution and its consequences. The uterus was fixed and there was bulging downwards of the pouch of Douglas with two fluctuating points. Each was aspirated, 3½ oz. and 1½ oz. of clear serum being drawn from them. The intestines were matted forming a large hypogastric tumour which varied with their distension. The patient speedily recovered after the aspiration, but had a slight relapse at her next menstruation, the temperature rising to 100° F. The researches of Dr. M. Duncan and J. Williams tended to the opinion that these cases were more common than is supposed and were often diagnosed as hæmatocele. The diagnosis between serous and purulent perimetritis was only certain after aspiration.—Mr. BURTON'S theory that these effusions were due to pelvic hæmatocele was opposed to the author's opinion that they were due to physiological congestion of the uterus during menstruation being changed into inflammation (metritis) by a chill, such inflammation spreading by continuity of tissue either along the Fallopian tubes, or through the uterine tissue to the peritoneum. Extreme cases of bulging of the pouch of Douglas were alluded to, caused, as Dr. John Williams has shown, by adhesive lymph fixing the intestines above and so preventing the serous fluid rising up into the pelvis.—Mr. DORAN said the case tended to prove the true signification of the term "serous perimetritis." Some irritant material from the tubes or elsewhere set up peritonitis, the uterine tubes and intestines happened to adhere in such a manner as to cut off a segment of the peritoneum. This was the first essential condition. The inflammatory process not being of a low type, serum instead of pus was poured out into the portion of peritoneum shut off from the general cavity. This was the remaining essential feature in that accidental variety of pelvic peritonitis, conveniently termed "serous perimetritis." He could not understand Dr. Routh's theory about the share which the posterior layer of the broad ligament might take in this disease. He described the actual anatomical relations of the parts, and pointed out that they explained the rapid matting of the ovary tube and broad ligament in such cases, but in some the intestine might displace the tube and come into contact with the broad ligament and adhere to it.—Mr. THORNTON wished to emphasise the remarks that had been made as to the inflammation forming serum instead of pus, and to point to the analogous conditions frequently seen in the pleura. If advantage of this knowledge were not taken and the serum evacuated, then tension would lead to suppuration and its attendant dangers. But in the earlier reports of these cases aspiration and tapping usually led to suppuration and death, just as removal of serum from the pleura used frequently to end in empyema and death. The great fact brought out by Dr. Routh's case was that, properly performed, aspiration of the serum in these cases ended in speedy cure, just as did the removal of serum from the pleura in the present day usually end in cure. The difference in the result was to be found in the careful antiseptic management of the operation. Dr. Routh cleansed the vagina with corrosive sublimate lotion and packed it with iodoform gauze; hence the speedy cure. Had he with his aspirator introduced putridity into the peritoneal sac, suppuration, instead of cure, would have resulted.—Dr. A. ROUTH said a few words in reply, and the meeting adjourned.

EPIDEMIOLOGICAL SOCIETY.

Dissemination of Scarlet Fever by drinking the Milk of Diseased Cows.

A MEETING of this Society was held on Wednesday April 14th, Dr. Dickson, President, in the chair.

Dr. JAMES CAMERON read a paper entitled, "Observations on a certain Malady occurring among Cows at a time when the Milk produced by them disseminated Scarlet Fever," of which the following is an abstract. The author began by stating that he proposed to lay before the Society a short description of a cow disease which had been the subject of investigation by Mr. W. H. Power, Dr. Klein, and himself during a recent inquiry into an outbreak of scarlet fever which occurred in certain districts in London and in Hendon amongst consumers of milk derived from a dairy farm situated within his sanitary district. It was not his intention to discuss the circumstantial evidence which led to the discovery of this disease amongst the cows, or which proved its connexion with the milk. These were respectively in the hands of Mr. Power and Dr. Klein. The disease is certainly not a new one; it has been known to some farmers and cowkeepers, at any rate, as a catching malady under the designation of sore teats, blistered teats, and the like; but it has never hitherto been recognised or described as a specific contagious disease amongst cows, or considered to have any concern with the causation of scarlet fever in the human subject, and has commonly been regarded as a malady of little importance. After giving an account of the farm, and speaking favourably of its sanitary condition, the author stated that the disease first appeared in some newly purchased cows, which had arrived about a fortnight before the first cases of scarlet fever occurred among consumers of the milk. It was subsequently ascertained that one of these cows, which was the first sufferer, introduced the disease into the herd, the malady spreading from shed to shed until the whole herd of 100 cows, with very few exceptions, was attacked; while, coincidently with the spread of the disease among the cows and into the various sheds, scarlet fever made its appearance, and continued to prevail among the consumers of the milk procured from these sheds. Dr. Cameron described the disease generally as a specific contagious disease, occurring usually in the first instance amongst newly calved cows, and capable of being communicated to healthy cows by direct inoculation of the teats with virus conveyed by the hands of the cowman. The disease may continue from four to six weeks, and is characterised by general constitutional disturbance, a short initiatory fever, a dry hacking cough, sometimes quickened breathing, sore-throat in severe cases, discharges from the nostrils and eyes, an eruption on the skin round the eyes and hind quarters, vesicles on the teats and udder, alteration in the quality of the milk secretion, and well-marked visceral lesions. The author then proceeded to discuss the symptoms in detail, and, referring to the eruption on the teats and udder, stated that from five to seven days after the commencement of the illness one or more teats became much swollen, and vesicles or bullæ shortly make their appearance upon them. These vesicles are usually rubbed and broken in milking, leaving sores with raised ulcerated-looking edges; at this period the disease appears to be easily conveyed to other cows. Shortly after the vesicle has been broken a brown scab forms upon the sore, and this may remain from ten days or a fortnight to five or six weeks, a thin discharge escaping from beneath it until the sore is healed. There is a tendency for the milk to become ropy during the illness, but this is not always present, and as a rule this condition is not apparent until the milk has stood for five or six hours; hence the milk from this farm was distributed before this peculiarity had had time to show itself. After describing the differences between cow-pox and the disease in question, Dr. Cameron urged the necessity for the examination of cows and for the removal of all suspected animals from the milk business, and he expressed the hope that the Government would see fit before long to institute some means of more effectually protecting the general public against the recurrence of these disastrous outbreaks of disease which are due to milk.—In the discussion which followed, the President, Drs. Murray, Pringle, Hicks, and Saunders, and Messrs. Barham, Smee, and Shirley Murphy took part.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

THE second annual general meeting of the Medical Officers of Schools Association was held at the rooms of the Medical Society, Chandos-street, on Thursday, May 6th. The chair was taken by the President, Dr. Fuller; and, the minutes of the last meeting having been read and confirmed, the report of the Council was presented, and adopted on the motion of Dr. Alder Smith, seconded by Dr. Brett. The report alluded to the resignation of Dr. Diver, which had been accepted by the Council. Dr. Fletcher's paper on the Management of Athletics in Public Schools had been published by Mr. Lewis, and copies had been sent to each member of the Association and to the head masters of the public schools. Sir Andrew Clark, Bart., consulting physician to the East London Hospital for Children, and William Scovell Savory, Esq., F.R.S., surgeon to Christ's Hospital, had been elected members of the Association by the Council on Feb. 10th.

The following gentlemen were then elected members of the Association:—Dr. Batterbury, medical officer to the Berkhampstead Grammar School; Dr. Hetherington, medical officer to the Ipswich Grammar School; Surgeon-Major Pratt, medical officer to the Royal Military Asylum, Chelsea; Dr. Edward Penny, medical officer to Marlborough College; Howard Marsh, Esq., senior surgeon to the Children's Hospital, Great Ormond-street; and F. W. Salzmann, Esq., medical officer to St. Mary's Hall School for Daughters of Clergymen, Brighton. Dr. George Buchanan, medical officer of the Local Government Board, was elected as an honorary member.

The audited accounts, which exhibited a satisfactory balance in the hands of the Treasurer, were then presented and adopted.

The following gentlemen were elected as officers for the year 1886-7:—President: W. S. Savory, Esq., F.R.S. Vice-Presidents: Sir Andrew Clark, Bart.; Dr. Farquharson, M.P.; Dr. Fuller; Surgeon-Major Evatt. Treasurer: Noble Smith, Esq. Hon. Secretaries: Dr. Alder Smith; Dr. Chas. Shelly. New members of Council: Henry Armstrong, Esq. (Wellington); Brudenell Carter, Esq.; Shirley Murphy, Esq.; Dr. J. Ellison (Eton).

A vote of thanks to the retiring President, Dr. Fuller, was proposed by Mr. Carter, and carried with acclamation.

Dr. Fuller, in reply, briefly reviewed the history of the Association, which now numbered eighty-three members, and quoted instances in which the results of its labours had already proved useful to members of the profession as well as to the public; he was glad to welcome Mr. Savory as his successor in that chair, because he was a man whose position at the head of the Association could not but add prestige to its labours and authority to its conclusions.

Mr. Savory accepted the presidency as a special compliment from the members of the profession who knew him best, and the more gladly because he could thoroughly assent to the purposes for which the Association was founded. He knew that the Association had already done good work, that it was now doing good work, and he believed that it would do still better work in the future by the attention which it directed to the prevention of disease in its endeavours to discover the causes which provoke it.

Dr. Haigh Brown then read a paper on the "Causation of Follicular Tonsillitis." In the course of the discussion which followed the reading of the paper, Mr. H. Armstrong argued against the contagious nature of tonsillitis. Dr. Fyffe, Dr. Brett, and Mr. Statham were not prepared to admit the contagiousness of the disease, while believing that many cases had an insanitary origin. Dr. Alder Smith took a similar view, and considered that it would be a very serious thing if every case of follicular tonsillitis must be isolated on the ground of avoiding the spread of the disease. He agreed with Dr. Fyffe and other speakers in recognising at least three types of the malady, but they were certainly not always easy to differentiate: a persistent albuminuria he should regard as evidence of diphtheria, even in the absence of other specific symptoms of that affection. After Dr. Haigh Brown had replied in detail, the President proposed a hearty vote of thanks to him for a valuable contribution to an important subject, which was unanimously accorded. The members subsequently dined together at the Holborn Restaurant.

ACADEMY OF MEDICINE IN IRELAND.

Villous Disease of Kidney and Rupture of Heart.—Cancer of Liver.—Spontaneous Rupture of Heart.

AT a meeting of the Pathological Section, held on Feb. 12th,

Dr. THORNLEY STOKER exhibited the Kidneys and Heart removed from the body of a gentleman who had recently died at about the age of seventy-two years. For ten years preceding his death he had suffered from occasional attacks of renal colic and hæmaturia. The loss of blood at times had been enormous, and the length of the hæmorrhages had varied from a day or two up to ten or twelve days. A post-mortem examination showed that the immediate cause of death was rupture of the left ventricle of the heart, due to fatty degeneration and hæmorrhagic infarction of its anterior wall, the result of embolism of the anterior coronary artery. This and other diseased conditions of the vascular system were evidently secondary to kidney disease. The left kidney was the seat of chronic nephritis, and its sinus contained two oxalate of lime calculi as large as hazel nuts. The right kidney weighed 1 lb. 7 oz.; its substance had almost disappeared, and was replaced by a number of spaces filled with blood-clots in different stages of formation—some being old and well-formed, while others were recent and scarcely solidified. The pelvis of the ureter was filled with thin stirabout-like matter, which proved to be disintegrated blood. The specimen had then been carefully reported on by Dr. Alex. M'Kee, who discovered in the sinus, infundibula, and calyces of the kidney extensive villous growths, presenting the usual dendritic character.—Dr. JAMES LITTLE said he had watched the patient for the last ten years, although he had not seen him for eighteen months before his death. He had been during ten years subject to the attacks of hæmorrhage. What usually happened was, that when going home in the afternoon from his office he would begin to feel pain, which usually came in the left loin, but sometimes in the right. He used to get into bed as quickly as possible, and the pain usually got worse and worse, and went down towards the groin and into the testicles, and had all the characters—as he was informed, for he never saw him while suffering from one of those attacks—of renal colic. Morphia never relieved him unless it was administered in such quantities as to stupefy him. The only thing that benefited him was a very hot application to the loins. The pain usually lasted twelve hours, and sometimes longer. Whenever he had pain he always had hæmaturia, but occasionally he had hæmaturia without pain.—Dr. J. W. MOORE said the present case proved that renal colic was produced by the passage of blood-clots. An instance of this recently came under his observation in the Meath Hospital. Another point of great interest was illustrated by a case which he saw a year and a half ago. It was that of a gentleman aged sixty-nine, who had for many years suffered from gout in his system, and who had been in the habit of passing quantities of oxalate of calcium in his urine. He was of active habits, and was suddenly laid up with an attack of pneumonia. His convalescence from this was protracted, and he had to give up all active exercise. He was a good horseman, and had been in the habit of taking daily exercise on horseback. When his convalescence was fully established he went out riding one day, and came home with a great desire to micturate. On doing so he was horrified to find that what he passed was almost pure blood. He sought advice, but in a very few hours his urine became perfectly limpid and pure. He (Dr. Moore) examined the bloody and also the pure urine, and found both to contain large quantities of calcium oxalate, the microscope showing them to be full of the calculi. He made a good recovery, and was not troubled with bloody urine afterwards. There was no pain in his case, because the calculi were not large.—Dr. DUFFEY thought they should look for something more than fatty degeneration in order to account for the rupture of the heart. He did not hear whether Dr. Stoker had said that there was fatty degeneration of the muscle of that organ; but if fatty degeneration *per se* had been the cause of this rupture, then they should meet with ruptures of the heart more frequently.—Dr. HENRY KENNEDY said that in cases of this kind hæmorrhages were commonly quite independent of both the kidneys and the heart. He had seen a number of cases of persons subject to fatty degeneration, in which fat existed in large quantities all over the body, and the individuals were subject to terrific fits of epistaxis, and yet afterwards made perfect recoveries for the time being. He looked on it as almost a necessary condition in those cases that hæmorrhages would occur independent of the state of the kidneys. He thought this gentleman must have had the gouty poison in him, and that it was relieved from express determination to the feet or elsewhere by these hæmorrhages.—Dr. STOKER, in reply, said he looked on these hæmorrhages as depending on a male change of life.

Dr. JAMES LITTLE exhibited and discussed a specimen of Cancer of the Liver. On Jan. 1st a lady's nurse-tender, aged forty-four years, was brought to the Adelaide Hospital suffering from profuse hæmoptysis. She had always been a delicate woman, and during the past year particularly so, the chief ailment from which she suffered having been pain in the epigastrium, brought on by eating solid food. The existence for twelve months of the epigastric and interscapular pains, and the circumstances of their having grown worse during the last three months, and of their having been particularly bad on the day preceding the hæmorrhage, seemed to him sufficient to justify the diagnosis of an ulcer in the stomach. Another circumstance tending to the same conclusion was that the blood was very bright in colour, and not of the dark colour that usually came from the stomach. She only lived twenty-four hours after her admission, and had several profuse hæmorrhages before her death. On post-mortem examination the stomach was found to be quite healthy, with the exception of a patch near the lesser curvature, about the size of half-a-crown. The liver weighed 4 lb.; almost the whole of the right lobe was occupied by one large mass, which presented in places a white and in places a yellowish-brown colour, and which was very firm and dense, cutting almost like cartilage. This mass was bounded by an abrupt line of demarcation from the rest of the liver. The remainder of the liver, consisting mainly of the left lobe, was very tough, and presented the characters of cirrhosis. The vena porta was filled with a soft dark thrombus. On microscopic examination the mass in the right lobe of the liver was found to be cancerous in nature, consisting of loculi of firm fibrous tissue, completely filled with polygonal-shaped cells.

Dr. FOOT communicated a case of Spontaneous Rupture of the Heart. The subject of the event was a car-driver, sixty-six years of age, admitted to hospital exactly a fortnight before his death, complaining simply of weakness and shortness of breath. He said he had been only ailing a week before admission. At the time he came under observation his feet and legs were œdematous, the action of the heart weak, slow, and unequal, his colour pale, and the skin of a satiny smoothness. His appetite was good, and urine free from albumen; and under the use of rest, meat, and wine, with tonic doses of digitalis and nux vomica, he frequently said he was daily gaining strength, but never showed any inclination to leave his bed. He slept a great deal, and often had to be aroused when the class came round. His sleep was never of a lethargic or comatose variety. On the morning of Feb. 9th, 1885, he was found dead in bed. There was no indication of any discharge from the stomach or bowels having taken place, nor was there any disturbance of the bedclothes. The distended pericardium, when slit open, gave exit to blood-stained serum, and contained twelve ounces of jet black coagulum, part of which was connected with a longitudinal rent in the anterior surface of the left ventricle, midway between the apex and base and close to the septum ventriculorum. The pale, soft, and greasy muscle of the heart had obviously been the seat of fatty degeneration, the condition which, above all others, predisposes to rupture.—The PRESIDENT (Dr. T. E. Little) remarked that a feature in this case was the very large size of the rupture; and its occurrence under the circumstances described, during sleep and without any muscular exertion, was rather unusual. Ruptures of the heart were generally longest at the inside, and passing obliquely outward towards the pericardial surface until they formed a pretty small rent at the outside: and this was an argument in favour of what Dr. Stoker had, in connexion with his case, indirectly put forward—namely, that rupture of the heart in many cases took place gradually.

Dr. WALTER SMITH exhibited the Viscera taken from a man who died of cardiac disease.

Reviews and Notices of Books.

The Insane in the United States and Canada. By D. HACK TUKE, M.D., LL.D. London: H. K. Lewis. 1885.
Statutes of the United States, and of the several States and Territories, relating to the Custody of the Insane. By C. F. FOLSOM, M.D. Philadelphia. 1884.

DR. TUKE'S book is chiefly composed of the impressions received during a recent tour among the asylums of Canada and the States. He has added thereto much useful information in regard to the existing provisions for the insane, and in a chapter devoted to Dr. Rush, the father of American psychiatry (whose portrait serves as a frontispiece to the work), a history is given of the treatment of the insane in the United States. Of Dr. Rush, who died in 1813, aged sixty-seven, the author records that he used restraint-chairs, privation of food, shower-baths of fifteen minutes' duration, and in extreme cases the fear of death, or terror, &c. He recognised, however, the value of employment, sympathised with Pinel and Tuke, advocated separate establishments for dipsomaniacs, and recognised moral insanity. Rush held that the bloodvessels of the brain were the primary seat of insanity, and consequently used blood-letting extensively as a remedy—in a quoted case to the extent of 200 ounces in fifty-six days.

Pennsylvania appears to have been the first of the States to establish an insane hospital at Philadelphia in 1752; Virginia followed in 1773; yet it was not until 1832 that the provision of treatment for all insane persons was regarded as a State duty, and after this date asylums multiplied rapidly. Dr. Tuke gives a list of ninety-four now existing. The total number of insane in 1880 was 91,950, yielding the proportion of 1 in 369 of native whites, and 1 in 237 of foreign whites above the age of fourteen years. In asylums were 40,992, of whom 5·4 per cent. were reported under restraint by camisole, muff, strap to bench, handcuff, ball and chain, crib bed, &c. The crib bed is probably not regarded as restraint by many physicians, and not recorded as being so. In some asylums no restraint whatever is used, but in illustration of the possible abuse of the crib bed, the author points out that one asylum possessed fifty. Padded rooms are very rare. Suicides formed 1 per cent. of the deaths. Epileptics are not aggregated as a rule. Medical treatment presents little for special comment. Dr. Tuke concludes that English lunatics are more difficult to manage than American, and that general paralysis is less common among the latter. Out-of-door life and employment is less resorted to than in England. The American asylums have the advantage of being of moderate size, so that the possibility of individual interest in the patients and their treatment is ensured, and rendered more probable by the larger medical staff employed, this being 1 to 150 patients, as compared to 1 to 300 in England. Many of the assistant medical officers are married men, and it is asserted with probability that better men are thus attracted to and retained in the service; these assistants are also more liberally paid than with us. In several asylums lady physicians are on the staff. The dietaries strike Dr. Tuke as being more liberal and varied than those of British asylums. Segregation in the care of chronic lunatics is being carried out at Kankakee, and elsewhere, and appears to be satisfactory in regard to comfort and economy.

Dr. Tuke briefly summarises the lunacy legislation in regard to admission to asylums, which is the most important part of Dr. Folsom's dry and uninteresting work. At the same time Dr. Folsom must be credited with having discharged an unthankful office in condensing with perspicuity a heap of very unattractive procedures, only to be regarded as legal experiments on insanity, which is manifestly considered as a *corpus vile*. The simplest admission procedure obtains in Connecticut, where a request by a friend, with a medical certificate, suffices. In other States, as in Pennsylvania, two medical certificates, sworn before a magistrate, are required. In other instances, as in Massachusetts, a judge must *certify* that "*he* finds the person committed is insane and fit for treatment in an asylum." Admissions are, however, permitted on emergency certificates. Lastly, as in Illinois, admission is only possible after *trial by jury*. The sketch which Dr. Tuke gives of this last procedure justifies the illimitable use of expletives in regard to it which one of the alienist physicians of the State applies unsparingly. More revolting inhumanity can scarcely be conceived than the illustration quoted from Mr. Wines, the Secretary of the Illinois Board of Public Charity. Notwithstanding all these precautions, thirteen persons sent last year to the Utica Asylum were declared not insane, an emphatic warning of the imperfect protection afforded by magisterial intervention.

Dr. Tuke records that the managers of one of the State asylums of the highest repute complains of the want of confidence and of the suspicion of the public. The author might have added to this the recent endorsement by an American judge of the quotation from Harrison, that "every superintendent of a hospital desires the wards to be full, and where the inmates are pay patients there exists a temptation to detain them."

Dr. Tuke's book is interesting in spite of its innumerable facts and statistics, and is valuable alike as a book of reference and from its suggestiveness. It will probably be as warmly welcomed across the Atlantic as here, being remarkably free from any prejudice that could offend American critics.

The Mammalia in their relation to Primeval Times. By OSCAR SCHMIDT. (The International Scientific Series, Vol. LIV.) With 51 Woodcuts. Pp. 308. London: Kegan Paul, Trench, and Co. 1885.

THIS work may be regarded as an exposition of the theory of descent illustrated by examples drawn from each of the orders of mammals that possesses a palæontological history. The dominant feeling and idea of the author may be gathered from a single paragraph. He traces the history of the horse and its descent from the Palæotherium, or three-toed horse, through the Anchitherium and Hipparion in Europe on the one hand, and of the parallel, but more perfect, series in America of Orohippus, with four toes; Mesohippus, with three complete and one rudimentary toe; Miohippus, with three toes; Protohippus, with two rudimentary and one fully developed toe; to the horse, with one toe and traces only of the two others, and then remarks that, whilst Owen looks upon this as a providential transformation designed for the benefit of mankind, he looks upon it as an adaptation of the limbs of these animals to the formation of the ground and to the incoming of plains which originated during the Tertiary period. Schmidt assigns the credit to D'Alton of the doctrine of adaptibility generally ascribed to Goethe—the doctrine that "form conditions the life and acts of the creation, whilst each fashion of life with reflex forcible action works on the form." He dwells on the phenomena of convergence whereby animals placed under similar circumstances have a tendency to resemble each other in the modification of their organs; and we need hardly add that he considers in their main bearings the palæontology and embryology of the monotremes and marsupials, the edentata and whales. The work is well worthy of perusal by all those who wish to make themselves familiar with the present aspect of science in regard to the theory of evolution.

The Asclepiad. No. 10, Vol. III.

THE article on the Cardiac Pulmonic Balance is most originally thought out by Dr. Richardson, and well worthy of perusal. "The Poverty of Wealth" is an amusing narrative, showing that the motto of the *Journal of Public Health and Sanitary Review* ought to have been "National Wealth is National Health," and bearing generally on the value of hygiene and sanitation in promoting health. Antonio Scarpa is the subject of the biographical notice and portrait. "The life of Scarpa is eventful only through his labours. He is from the beginning to the end of his career the professor; his genius, observation; his force, industry; his fame, purity—purity in exactitude, patience, exposition, initiative, direction." In the *Opuscula Practica* there is a page or so on a "Proper Temperature for Mental Work." Here it is stated that if the temperature be unequal, study is unequal; and that the best degree of temperature for mental work is 64° F. or 18° C. If the temperature falls much below this, there is a relaxed state of body and mind, which soon leads to fatigue and exhaustion. No doubt Dr. Richardson is right, but we think allowance should be made for idiosyncrasies. We are not all gifted with the perennial energy of the author of *The Asclepiad*, and it is most likely that some of our dull brains are incapable of experiencing the variations in surrounding temperature in the manner above alluded to. Likewise we are disposed to join issue with the author in thinking, *with* the poet Cowper, that composition is rather exhausting in its nature.

New Inventions.

A SOLID CATHETER.

THE instrument shown in the woodcut is intended to combine the weight of a solid metal bougie with the advantages of a catheter. It consists of a silver catheter, into which, in place of the ordinary stylet, a soft metal rod fitting the tube is passed right up to the end (in the woodcut the rod is not represented long enough). The effect of this is to render the catheter practically solid, and the weight is equally distributed through its whole length. After introduction the rod is withdrawn, and a hollow catheter remains. The rod appears straight when

withdrawn; but in the catheter, owing to its softness, it follows the curve as dotted in the woodcut. As an instance of the difference of weight made by the rod, I have weighed a No. 9 catheter, selected at random from my set, which weighs without the rod 6½ dr., and with the rod 15 dr. The rods can easily be fitted to any metal catheter.

VALENTINE MATTHEWS, M.R.C.S., L.S.A.

Suffolk-street, Pall-mall, S.W.

A NEW DISINFECTOR.

WATERCLOSETS should require no disinfection; they should be so constructed that their contents are completely removed, and that they are thoroughly cleansed and filled with clean water. The use, therefore, of a disinfector presupposes a defective apparatus, which should be exchanged without delay for one more perfect; but if circumstances should render this impossible, and the best have to be made of faulty apparatus, the use of a disinfector is then necessary. Mr. H. E. Pollard, of Duke-street, Adelphi, has sent us the Sweet Home Patent Disinfector which is an ingeniously constructed receptacle made of earthenware, and containing permanganate of potash crystals; it is intended to be fixed within the pan as close to the flush as possible, and on each occasion of use of the closet water passes into the disinfector and washes round the pan of the watercloset solution of permanganate. It has the advantage of being very simple in its construction, and gives no opportunity for the retention of dirt, and will be found useful under the circumstances we have mentioned.

HEALTH OF CAVALRY HORSES.

THE very satisfactory condition of the horses, as shown in the Annual Statistical Report of the Army Veterinary Department for the year ending December 31st, 1885, reflects great credit upon the branch of the service so ably and efficiently conducted by Mr. Fleming. It appears that the average strength of the horses employed in the United Kingdom during the year was 11,778; the admissions into hospital from sickness and injury amounted to 589 per 1000; the deaths to 18·7; the number "cast" to 91·0; and the constantly non-effective from sickness or injury to 38 per 1000 of the strength. The admissions and casting were considerably lower, but the death-rate was 1·5 per 1000 higher than in the preceding year. The table showing the average number of days each horse was ineffective is a valuable addition to the return. The reduction in the number of cases was most marked in those from skin disease, sprains and accidental punctures, contusions, contused and punctured wounds, and collar-chain gall. There was a considerable increase in the cases of catarrhal fever, influenza, and strangles. The two classes—diseases and accidents of the locomotory apparatus, and surgical diseases and accidents—furnished upwards of three-fifths of all the admissions, and together amounted to 366 per 1000 of the strength. The increase in the mortality compared with that of 1884 was chiefly due to an outburst of glanders and farcy among the horses of the 5th Lancers after their return to England from Suakim, where the diseases are believed to have been contracted. The regiment arrived in England on June 13th, and on the 15th the first case of glanders was reported; between that date and July 11th 7 cases of farcy and 4 of glanders occurred; since then the regiment has been entirely free from the disease. Mr. Fleming observes that "to the prompt and energetic measures adopted (immediate destruction of the diseased, complete segregation of those presenting any suspicious symptoms, close inspection of every horse two or three times a day, picketing out in the open a horse's length between each horse, and the most scrupulous care with regard to watering, cleansing, disinfection, &c.) must be ascribed the wonderfully rapid 'stamping out' of what threatened to be a most serious invasion of glanders." Only one other case of glanders occurred during the year, in the Royal Artillery at Shorncliffe; it was "due to infection brought into the barracks by an officer's private horse kept in a stable attached to his house." Prompt measures were at once taken, and the disease did not spread. The most fatal class of diseases was that of the respiratory apparatus, which gave rise to 60 deaths, or upwards of a fourth of the whole mortality; and next to it stand diseases and accidents of the locomotory apparatus, by which 58 deaths were caused.

An interesting table is given of the admissions and deaths by ages, which shows that the highest percentage of sickness occurs among the five-year-old, and next to it among the four-year-old horses, while the highest death-rate under fifteen is among the four-year-olds. Among the causes of casting "old age" furnishes much the largest number, 457 out of a total of 997 being returned under that head, but no information is given as to the exact ages of the horses so "cast." We would suggest that the addition to Table G. of a column for the "casting" would add much to its value. The average price realised for "cast" horses was only £9 19*s.* 1*d.*, being £1 6*s.* 1½*d.* less per horse than in 1884, a result probably due to the depression in trade and agriculture. Mr. Fleming has given us a very interesting report, in which he has gone more into detail than previously, and we most sincerely congratulate him and his staff upon the successful result of their labours which he has been able to record.

THE LANCET.

LONDON: SATURDAY, MAY 15, 1886.

WE were pleased to hear from Sir JAMES PAGET on Wednesday, the 12th inst., when addressing the students and their friends after the presentation for degrees, that there was a great hope of such modifications being introduced into the University as would fairly meet the views of those who pressed for the establishment of a Teaching University in London, and who were not content with a mere metropolitan examining board. He indicated, as we think quite rightly, that such alterations must be by way of addition to the present system, rather than by fundamental changes therein. The programme of the University has been steadily maintained as an institution for the chosen few from everywhere during an existence of fifty years; for next year will be its jubilee, and, as Sir JAMES PAGET pointed out in his able and interesting speech, it has justified its existence as an examining board and by its indirect effect on education so completely that it would be unwise, and indeed impossible, for it now to make a complete change of front and become a local university only. Local teaching institutions might be more closely affiliated to it, and local teachers more closely identified with it, without altering the world-wide influence it now exercises through its examinations. The fear of lowering its standard of merit is always put forward as the one argument against reform; but it is absurd to suppose that it ever can become, or is expected to become, an institution whence all who desire degrees, medical or otherwise, are to obtain them on easy terms. Average degrees for medical students in London must be granted by the corporations. But increased facilities for obtaining degrees, internal reforms giving a substantial recognition and power to teachers are still demanded from the University authorities, and are quite beside any question of lowering the standard. We may refer to one or two examples to show their necessity. The fixing of two preliminary scientific examinations in a year was only obtained after years of agitation, and was brought about by the influence of the teachers only, and in the teeth of a strong opposition led by the examiners in science, and encouraged by most of the then members of the Senate. Indeed, if the Vice-Chancellorship had not fallen to such a man as Sir J. PAGET, on the death of the late Master of the Rolls, we doubt if the additional examination would have been in existence now. Yet on its first institution in January last, 34 students presented themselves for the entire examination and 17 passed; 31 took two subjects and 22 passed; whilst 21 out of 33 candidates passed in one subject only; that is to say, 98 candidates altogether were examined, of whom 60 passed. A very large proportion of these 60 could not have spared the time and money to proceed to the degree if there had been only annual examinations. But the Senate must not stop at this; 155 candidates at the Intermediate M.B. Examination last year with a rejection of 59 call for a similar change in this examination. There is no reason whatever why these 59 should not be re-examined before the end of another year. Two Preliminary Scientific Examinations in the year must be followed by two Intermediate M.B. Examinations in the same period, and were teachers fully represented on the Senate this would quickly be arranged. Another imperative reform is a reconsideration of the regulations of attendance on lectures and hospital practice for the Final M.B. Examination, which in the present form are frequently quite prohibitory to the candidate. To pass from our own profession, we find teachers urging the institution of a degree in Engineering Science, and even hinting at a necessary modification of that almost sacred fetish, the Matriculation Examination, whilst others request complete revision of the regulations for the LL.B. degree. No such suggestions ever come from within; every change is initiated from without, and is only granted after long delays and wearisome agitation. This is simply because the authorities have lost touch with teachers and students, and we can only hope that the election of Sir EDWARD FRY and the new Senators will prove to be the first step towards the uprooting of this feeling, which has done so much to hinder the due development of the University in adapting itself to modern requirements. The position of infallibility assumed by many of its founders and older Senators cannot be too quickly abandoned.

IN a recent number we referred to an interesting paper by Dr. JAMES CAMERON, the Medical Officer of Health for Hendon, which had been read before the Epidemiological Society, and which gave account of a disease occurring amongst the cows on a farm in his district at a time when the milk which they produced disseminated scarlet fever amongst its drinkers. The Local Government Board have just published a Report by their inspector, Mr. W. H. POWER, showing the relation of this cow malady to the human disease. There has probably not been issued for many years a paper on a subject of greater importance, for upon the proof that a human disease which destroys every year thousands of lives in this and other countries has its origin in an affection of the cow must depend the means to be taken for its prevention. Until now, inquiries made into outbreaks of scarlet fever disseminated by milk had not afforded further evidence than that the disease was produced by milk which was infective from the time of leaving the farm; and although the absence of any knowledge of the means by which it acquired this property had, after careful investigation, raised a strong presumption that the cow might in some way or other be responsible, the final link has been wanting which is required to complete the chain of evidence. It is this link which Mr. POWER'S Report now supplies; but it goes even beyond this, for it shows by circumstantial evidence of the most conclusive nature that the cows upon the Hendon farm were only capable of producing milk which possessed this property at a time when they were themselves suffering from a disease which is characterised by the appearance of vesicles and sores on the udder.

It is impossible here to do justice to the admirable and exhaustive argument by which Mr. POWER supports his conclusions but we may briefly narrate the circumstances of the outbreak which his inquiry brought to light.

Digitized by Google

The story is of a farm having three sheds, the milk from these sheds being received respectively by three retail vendors. Into the first of these sheds were admitted three cows newly arrived from Derbyshire, and which had been placed for a few days previously in a quarantine shed. These three cows were followed by four other newly arrived cows, which replaced the first in the quarantine shed, and were afterwards distributed, two in the first shed which had received the Derbyshire cows, and two in the second shed, where they remained for a short time and were then transferred to the first shed. Scarlet fever appeared among the customers of vendors receiving milk from the first two sheds, shortly after the admission of the newly arrived cows into the sheds with the other cows; among drinkers of milk from the first shed the disease occurred in large proportions and attacking them in increasing numbers; among the drinkers of milk from the second shed, first in small numbers, and then, after an interval, in larger proportions, the drinkers of milk from the third shed remaining free from disease until almost the end of the inquiry. Finally, a cow disease was found to have attacked the Derbyshire animals, and subsequently those which followed them, extending to other cows in the sheds in which they were placed. The appearance of the disease amongst the cows immediately preceded that of scarlet fever amongst the milk vendors' customers. The interruption in the prevalence of scarlet fever among the drinkers of milk from the second shed corresponded in point of time with the removal of the two newly arrived cows from the second to the first shed, while its recrudescence again corresponded with the appearance of disease among other cows in the second shed. The proof was already strong; but, as if to complete it, at the end of the inquiry the additional evidence was afforded of an invasion by scarlet fever of the drinkers of milk from the third shed immediately after the cows in this shed were attacked by the same disease as that which had affected the others.

In face of such evidence we are compelled to accept the conclusion that the disease of the cow was related to that of man as cause is to effect. It is true that this evidence is only circumstantial, but the correspondence in behaviour of the disease of the cows with that of the milk drinkers is too definite to have been a mere coincidence, and we have no hesitation in expressing our belief that we are at last brought face to face with the origin of scarlet fever. It is difficult not to anticipate a possible result of this addition to our knowledge of its etiology. The possibility of exterminating this disease will be at once apparent, and it is satisfactory to know that Dr. KLEIN'S services have been enlisted for the further prosecution of the inquiry on lines which the Report indicates. The consideration whether these expectations will be immediately realised must be left until Dr. KLEIN'S labours are ended and his report presented; but, under any circumstances, the facts which are already known will give fresh impetus to the study of animal in relation to human diseases.

We cannot close this article without bearing witness to the patience and perspicacity which have created these hopes. The excellence of the work of the Medical Department of the Local Government Board has long since placed this country foremost amongst those which have contributed to our knowledge of disease, and certainly no recent investigation in England better promises to maintain this high character, or to confer greater benefit on man, than that recorded in the Report of Mr. POWER here brought under review.

THE Croonian Lectures of the present year are mainly remarkable for the assiduity with which Dr. LATHAM has attempted to introduce into general medicine an intricate, though necessary, knowledge of some of the intimate chemical processes which are collectively classified under the physiologist's term of metabolism. Were we able to picture accurately the various stages of the chemical processes occurring in the normal integration and disintegration of protoplasm, we should be possessed of knowledge which it is no exaggeration to say would speedily place within our grasp the secrets of nature. As an attempt to propound some of the most important vital chemical changes, every member of the profession must fully appreciate Dr. LATHAM'S labours. But in the present state of physiological science his arguments can only be considered as more or less probably correct. Our information of the way in which a molecule of protoplasm or even albumen is built up is so vague and uncertain, that we have no solid groundwork whereon to build a superstructure. If, then, physiology is so unsettled, pathology must for all purposes be likewise indefinite. At the outset Dr. LATHAM appeals in large measure in support of his views to an ingenious analogy—first made, we believe, by PFLÜGER—between the properties of certain cyanogen compounds and those of living protoplasm. This analogy is very striking, and even if it does not actually represent the truth, it probably gives some idea of the difference between living and dead matter. It is a question of a difference in power, in potentiality. The chemical composition, the mere number of chemical atoms, is the same in urea and ammonium cyanate. Urea, however represents dead matter, more stable but less energetic than ammonium cyanate, which is the representative of living matter in that it possesses energy with instability. Dr. LATHAM suggests that albumens are structurally cyanalcohols combined with a benzene nucleus. The energy of albumens comes from their being cyanogen compounds. He shows how the various amide products of the animal economy may be built up in the laboratory by various chemical interchanges.

What is rheumatic fever? Clinically it consists in the development of various well-known symptoms. How may these symptoms be excited? We have for many years past been taught to believe that causes acting on the central or peripheral nervous system may give rise to joint changes having a close resemblance to those of subacute rheumatism. Is rheumatism a disease of the nervous system? The experiments of Dr. B. FOSTER have shown that the introduction of lactic acid into the animal economy may be followed by the production of a certain set of symptoms closely allied in appearance to those of rheumatic fever. Does the lactic acid act on the joint structures and vessels directly or through the intermediation of the nervous system? Dr. LATHAM adopts neither of these views. The Croonian lecturer believes that the *materies morbi* of rheumatism may induce the arthritic signs by its action on

Digitized by Google

the trophic centres presiding over the nutrition of the joints. Lactic acid is formed in excess, but must be regarded as a companion symptom with the other phenomena of rheumatic fever. Not that the acid itself is harmless; possibly it also induces symptoms on its own account. Dr. LATHAM fixes on uric acid as the irritant to the central nervous system in rheumatic fever. Where and how is the excess of uric acid formed? In order to follow this problem it is necessary to know that there are such bodies as amido-acids. One of these of most importance in our present connexion is amido-acetic acid, glycocoll, or glycocine. This acid enters into the formation of many important substances. By heating it and urea together uric acid can be obtained. Glycocine may be formed in excessive quantities in muscular tissue; combined with cholic acid it forms a salt of bile. The liver, therefore, secretes it thus in combination. Now, there are several other ammonia compounds—leucine, tyrosine, and taurin,—all of which are probably dealt with by the liver, which most likely converts them into urea. The capacity of the liver in this respect may vary for different ammonia compounds. Imagine that the glycocine is not transformed, or only partially so, whilst the other bodies are acted upon, then we should have urea and glycocine together; a conjunction not difficult to imagine, and which possibly actually occurs with the formation of uric acid. But there is the difficulty; such processes are possible, but have not been proved to occur. On this view the liver is the great offender; on it the "sluggish" liver of our forefathers receives a new interpretation. There are many ways, however, in which the imperfect metabolism of glycocine may be brought about. Take an ordinary febrile catarrh, in which we may suppose that there is an excessive production of amido-acetic acid (glycocine) in the muscles. It goes to the various glands of the body—liver, spleen, kidneys. Some of it gets converted into urea, and we hear no more of it. Other portions combine with urea to form uric acid, with more or less disturbance of the nervous system, according as the eliminatory organs are in good working order or not.

The vaso-motor system figures largely in Dr. LATHAM'S attempts to explain feverish colds, rheumatism, &c. The vaso-motor system, as has been said of statistics, can be made to prove anything; any physiologist will grant such a proposition. The lecturer pointed out that muscles and glands have special secretory and vasal nerves; urari paralyses the former in muscle and atropine in gland. The vessels may be dilated without increasing the secretion or metabolism, but still, as a rule, vaso-dilatation means excessive disintegration or descending metabolism. Taking this as a guide, we can easily follow Dr. LATHAM through the varying effects of exhaustion, paralysis, and stimulation of the various parts, cutaneous, muscular, and glandular, of the vaso-motor system. In rheumatism the (what Dr. MOXON would call) "Secretary of State for the Vaso-motor Department" is in a condition of exhaustion—it has loosened its reins of government; the local departments therefore run riot; or, in other words, there is excessive disintegration and vascular dilatation—the consequences as regards glycocine and the like we have above considered; at the same time lactic acid is formed in excess. In rheumatism, therefore, we cannot blame the liver; it does its ordinary share of work, but too much is put upon it, hence the uric acid and morbid irritation of the nervous system. But in gout it is another matter; the liver is primarily at fault; its secretory cells are not acting up to normal, either from defective innervation or inherent weakness. It is possible that glycocine and urea may be conjugated by the renal tissue, and thus lead to the formation of the slightly soluble ammonium urate, some of which may pass away into the general circulation and be transformed into the soda salt which is deposited in the joints of gouty subjects.

The far-reaching nature of Dr. LATHAM'S subject is still further witnessed by its inclusion of the kidneys, as well as the liver, nervous system, spleen, and general physiological chemistry. A good deal depends on the kidneys: if they are sound the uric acid is readily eliminated; if not, if there be renal inadequacy, then more of the *materies morbi* circulates widely, and so induces the arthritic and other symptoms of gout and rheumatism. It is easy to picture the action of the poison in the blood on the *locus minoris resistentiæ* of various individuals, or the same individual at different times, with the production of gout at the heart, at the toe, at the stomach, and so forth. The arguments in support of Dr. LATHAM'S views afforded by appropriate treatment of rheumatism, gout, and diabetes by salicylic and benzoic acids and colchicum are not the least interesting part of the Croonian Lectures.

AT its last meeting the College of Physicians decided by a large majority of votes that the reformed constitution which had been drawn up by Dr. C. WEST was unnecessary for the due performance of its functions. The grounds upon which Dr. WEST based his proposals were plausible enough. Briefly stated, they were to the effect that the junior Fellows are not represented upon the Council, and that their interests have little chance to be considered in a body which contains so small a proportion of members having any direct connexion with a hospital or medical school. He proposed, therefore, that three standing committees should be appointed to deal with questions concerning (1) education, (2) professional interests, (3) public interests; such committees to consist each of two members of Council and three other Fellows of not more than ten years' standing, the members to be nominated by the Council and elected by the Fellows. The duties of these committees would consist in considering, reporting, and suggesting measures to the Council upon the various topics referred to them or initiated by them in their several departments. In that way he deemed it would be possible not only to interest the junior Fellows in the work of the College, but enable the College itself to take a more active part in many public and professional subjects than it now does. The reply of the Council to these suggestions was to the effect that the present system of appointing committees as occasion arises is preferable to any scheme of standing committees; that there already exists a Committee of Education and Examination, composed of delegates of the two Colleges; whilst the subjects alluded to by Dr. WEST as falling within the sphere of the College could be more speedily and efficiently dealt with under the present system. It was also pointed out in the debate upon the

Digitized by Google

subject that on several occasions questions have been raised by junior Fellows, many of whom have also been placed on committees where their interests are concerned. That the claims of junior Fellows have, at least for some years past, been adequately considered was shown in the fact that they did not support Dr. WEST in his endeavour to remedy their supposed grievances. In point of fact, the constitution of the College of Physicians is at the present day far more democratic than is generally supposed. Two years ago the Council received a severe check in the reference to them of a nomination list which had been framed without due consideration to the claims of certain Members to the distinction of the Fellowship; and there is no question that in the same way there will always be found means for the expression of opinion by the body of Fellows when this runs counter to the views of the Council. Indeed, the powers of the Council are comparatively limited. Except in the matter of nominations to the Fellowship, the Council, and Examinership, that body can only deal with subjects which are brought under its notice at a Comitia of the College. The Council has no power to initiate; its function is merely executive. It is open to any Fellow of the College to bring forward resolutions, and to move the reference of matters either to the Council or to a special committee. We are far from saying that there is not room for some improvements in the machinery of the College, and especially in the somewhat effete methods of election without nomination, of which an instance was seen at the last Comitia. By the resignation of Sir H. PITMAN the College was called upon to elect a representative to the General Medical Council. Every Fellow present has the right of proposing whomsoever he thinks best fitted for such an office, and although doubtless the Council have already decided amongst themselves whom it would be best to support, that support is presumably bestowed in their individual capacity. The gentleman chosen on this occasion will undoubtedly represent the College with dignity and intelligence. He holds high office in the College, and that of itself may be an argument for his selection; but we can imagine that occasions might arise when the most suitable representative to sit upon a Council of Education like the General Medical Council should fail to be chosen by reason of the clumsy method of election at present in vogue. The same applies with even greater force to the election of a President of the College. These, however, are matters which concern the Fellows themselves, and we have no desire to meddle with them. Nor do they come under the head of Dr. WEST'S proposals, which, although rejected, will have at least served the useful purpose of informing the College of the duties devolving upon it, and of the manner in which it may, without any change in constitution, best seek to fulfil them.

A VALUABLE essay has just been contributed by Dr. W. H. GASKELL to the *Journal of Physiology* on the structure, distribution, and function of the nerves which innervate the visceral and vascular systems. The recognition of the functions of the true vaso-motor nerves is of quite recent date, commencing with the observations and experiments of CLAUDE BERNARD, BROWN-SÉQUARD, WALLER, and others, about the year 1848, as may be demonstrated by a reference to MÜLLER'S Physiology, who speaks only of their action on the heart; and to BROWN-SÉQUARD'S lectures, in which the development of the subject is traced. Modern research has shown that the sympathetic system of nerves consists of groups or centres of ganglion cells, connected by means of afferent and efferent nerves with the cerebro-spinal nervous system, and that through these a number of reflex actions may be excited, which powerfully influence the movements of the viscera and vessels, and with them the nutrition of each and every part of the body. Dr. GASKELL, in the essay referred to, limits himself to the efferent nerves, which he divides into three groups: the nerves of the vascular muscles, which may be either vaso-motor or vaso-inhibitory; the nerves of the visceral muscles, which may also be either viscero-motor or viscero-inhibitory; and, lastly, the glandular nerves. His researches have been made exclusively upon the dog; partly because of the close resemblance between the distribution of its nerves and that of the nerves of man, and partly because our knowledge of the functions of the majority of the visceral nerves is based upon experiments conducted upon this animal. The more important points that he has ascertained in regard to the structure of the visceral and vaso-motor efferent nerves, are that the visceral nerves constitute the white portion of the rami communicantes, and issue from the spinal cord in definite sacral, thoracic, and cervico-cranial regions. They then enter into the ganglia of the visceral nerves—that is, into the lateral chain of the sympathetic, and the ganglia on the main stems of the vagus and glosso-pharyngeal nerves. The vaso-motor nerves arise from a more limited portion of the central nervous system, and run, Dr. GASKELL believes, in the outflowing stream of visceral fibres which occurs between the second thoracic and second lumbar nerves, entering the lateral ganglia and there losing their medullary sheaths. This great chain might therefore most appropriately be termed the chain of vaso-motor ganglia, instead of its present title of main sympathetic nerve. There is no satisfactory evidence that vaso-motor—that is, vaso-constrictor—nerves join or are contained in the vagus or other cranial nerve.

Special examination of the central origin of the spinal accessory nerve, which governs the peristaltic contraction of the œsophagus, stomach, and intestines, shows that the fibres in part arise from the cells forming Clarke's column (which set forms a ganglionated root) and from a non-ganglionated root in connexion with the cells of the lateral nerves, and that they leave the central nervous system amongst the fine medullated fibres which issue from the upper part of the cervical region, and pass by way of the rami viscerales of the accessory and vagus nerves to the ganglion of the trunk of the vagus, where they become non-medullated. Proceeding by analogy, Dr. GASKELL considers that the nerves which arise from each spinal segment are formed by three roots—an anterior non-ganglionated root in connexion with the cells of the anterior horn, a posterior ganglionated root in connexion with the cells of the posterior horn, and a lateral root, which, like the fibres of the spinal accessory, are again divided into a ganglionated root in connexion with the cells of Clarke's columns, and a non-ganglionated root in connexion with the cells of the lateral horn. The motor nerves to the rectum, bladder, and uterus receive

Digitized by Google

a double set of motor fibres—one from the cerebro-spinal, the other from the sympathetic system. The cerebro-spinal nerves pass to the hypogastric plexus, and thence to the organs in question by those visceral branches of the second and third sacral nerves which form part of the pelvic splanchnics, and are known as the nervi erigentes. The sympathetic fibres, on the other hand, pass to the inferior mesenteric ganglion along the rami efferentes of that ganglion, and thence to the hypogastric plexus. The former therefore issue by the sacral stream of visceral nerves, the latter by the thoracic stream. The functions of these two sets are opposed: the pelvic splanchnics innervate the longitudinal fibres of the bladder, rectum, and uterus; whilst the circular fibres which effect peristaltic action are under the control of the hypogastric nerves or lower abdominal splanchnics.

In regard to the vaso-dilator nerves, the existence of which is now generally admitted on the strength of the inhibitory nerves of the heart and the effects of stimulation of the chorda tympani, the small petrosal nerves, and the nervi erigentes, Dr. GASKELL'S researches show that they are medullated and of fine calibre, and that they leave the central nervous system by the cervico-cranial and sacral rami viscerales; thence they pass into the distal ganglia, where they lose their medullated sheath.

Dr. GASKELL'S memoir thus throws much light on the connexions of the sympathetic with the cerebro-spinal nervous system, and holds forth a hope that it will not be long before the objects and functions of the tangled plexuses we now call the visceral plexus are unravelled and made clear.

DR. OLIVER WENDELL HOLMES will be welcomed in this country by the reading classes of the community especially, and by the masses generally. The former will recognise him as an impressive and instructive writer; the latter partly as a humourist, partly as an American, and partly as a man of mark whom it is right to know. The medical profession, however, has a particular reason for hailing our guest with exceptional cordiality. He is for us in England the embodiment of an idea—unhappily an idea which has very few remaining embodiments, which is fast dying out, and by its death leaving a body of cultured men deprived of one of its most potent claims on the respect and confidence of the educated classes. It is useless to disguise from ourselves that, in developing the professional and scientific elements of Medicine as a vocation, we have not only neglected, but almost wilfully, if not willingly, abandoned its once scholarly and literary characteristics. It may seem a hard thing to say, but never in the history of our art were those by whom it is practised at a lower ebb as regards general scholarship, in spite of the acknowledged excellence of their attainments as technists. It has been by throwing aside the weight of scholarship that professional distinction has been won. The highest places in medicine are no longer held by men who, having achieved success in scholarship at the universities, "went out," as the phrase used to run, in physic. The long-cherished traditions of intellectual culture have been almost swept away, and now a young man is educated for the calling of a physician or surgeon as he would be for any other department of enterprise or industry; and with a view to the utilisation of every available force of which his brain may be capable in the particular business before him, he is not only encouraged, but required, to abstain from what is called the dissipation of mind-power in profitless—that is to say, not directly profitable—activities.

Dr. OLIVER WENDELL HOLMES, who, it must be remembered, is representative of the last generation rather than of the present, comes to us as a survivor of the intellectual and literary type, upon which our contemporary development is held to be such a marked improvement. He is a medical practitioner, but before that he was, and above it he is still, a "man of letters." We welcome him in our midst specially in that character, and it will redound to our advantage as a section of the community if we bestow more than a passing thought on the position he occupies. It will be well if the attention of our students is directed to this man of mark while he is among us, and if they are even for one moment reminded of a type which would seem to be becoming extinct (in the home country at least)—the literary scientist. We are, of course, all too busy with our daily work to bestow much time on the literature of medicine, but if only so old-fashioned and simple a book as AIKIN'S "Biographical Memoirs of Medicine in Great Britain from the Revival of Literature to the Time of Harvey" could be read by the practitioner of this last quarter of the nineteenth century, he would rise from the perusal with a feeling not far removed from humiliation provoked by the contrast displayed between the social positions occupied by physicians and surgeons in earlier and recent times. The difference is mainly, if not wholly, due to the specialising tendency of modern culture—a tendency which shows itself, perhaps, more disastrously in connexion with medicine than with any other branch of scientific pursuit. Is it inevitable and final, this choice of a narrowed intellectual path for the practitioner of medicine? Must he certainly be an expert in the art of healing, and nothing besides? Before we answer this question, and while we are doing so, let us mingle with our cordial and brotherly welcome to Dr. OLIVER WENDELL HOLMES a spirit of appreciative criticism, and try to learn how far we are the gainers or the losers by a policy of neglecting, if not of contemning, the gifts that were cultivated in the old times this visit of our revered guest invites us to recall, and in the possession and full fruition of which he has attained to an age crowned with honours and cheered by troops of friends.

IT remains to be seen whether the leave-all and please-all kind of legislation represented in the Medical Bill of the Government is to have the easy passage which its authors intended and hoped for. Clause 13 gives power to any two Lords of the Privy Council to order the registration of as many foreign graduates as they please, and not only so, but gives their two lordships power to order the Medical Council to register foreign diplomas and foreign graduates, which and whom they have distinctly refused to register. This is rather hard upon a profession which has been accustomed practically to govern itself and to be considered liberal and independent. But there is a tone of decisive frankness about the clause and its subsections which seems to imply that business is meant. Subsection 2, which says the Privy Council may make such order, adds emphatically "*and such order shall be duly obeyed.*" It really looks as if

Digitized by Google

Sir LYON PLAYFAIR meant to provide the medical profession through the Medical Council with masters, notwithstanding the general air of innocence and non-interference which pervades the Bill. Is it in contemplation to increase freely the number of foreign graduates? We have never been illiberal in this matter. Our own graduates and those holding our diplomas turn up in every country, and we like to have their diplomas recognised, though we are often disappointed. But to give a *carte blanche* to two Lords of the Privy Council to override the deliberate judgment of the Medical Council on the merits of a foreign diploma or a foreign graduate is certainly rather a strong proceeding, and would have produced a protest from any Medical Council worthy to represent the medical profession. Sir LYON PLAYFAIR has not made any public admission of the error of his estimate of the waste of the profession, or of the fact that many hundreds are entering it every year in excess of the number required to fill the vacancies in its ranks caused by death or in other ways. But even Sir LYON PLAYFAIR will not maintain that we need, on the score of numbers, to have recourse to the admission of doubtful foreign degrees and graduates. Why, then, this imperious tone in the clauses providing for the recognition of foreign degrees against the judgment of the Medical Council?

But it must be admitted that though the new power of the Privy Council is more accentuated in the matter of compelling the Medical Council to do that which it does not approve in the matter of foreign degrees, this power is significantly expressed in other parts of the Bill; notably in Part III., Clause 18, under the head of Micellaneous Provisions. This clause gives power to the Privy Council (any two Lords of it, Clause 19), under certain conditions, to supersede the Medical Council at any time in any matter or question, in which the Medical Council has omitted to exercise its powers under the Medical Acts or in this Act. Now, the Medical Council being the powerless and the timid body it has hitherto been, the taking of such powers may seem not unreasonable. But the very taking them is, in our judgment, the gravest condemnation both of the Bill and of the Medical Council. The Medical Council ought to be a body so complete in its own powers, and so perfect in its own constitution, as that the claim of such powers by the Privy Council ought to be out of the question. But these clauses seem to say on the part of the Government: "We see the impossibility of that Council, with all its rival and competitive jealousies in full play, doing anything thoroughly, or settling the new questions which are likely to arise under Clause V. and other clauses, on broad and just principles. We feel our own want of courage to deal boldly and firmly with the reform of our examining bodies; so we shall insert in the tail end of the Bill clauses which give us the right to interfere, without the initiative of either the Council or the individual bodies, and compel them to do what they ought to do or what we think they ought to do." Even if the direct representation of the profession be increased to six, as is said to be likely, we cannot accept a Medical Council so condemned as this is to be by the threat of being constantly over-borne and superseded by the Privy Council. The Crown—that is, the Privy Council—has the nomination of six members of the Council to begin with. If that is not enough, let the Lord President himself, or the Vice-President of the Committee, have a seat in it, and let the number of rivalries and jealousies be reduced by collective representation. But do let us have a Council that has complete and independent powers within itself, without requiring the constant interference of the Privy Council.

The corporations feel aggrieved, it is understood, at the Universities having powers individually to give complete qualifications, while they (the corporations) must act in conjunction—saving those happy bodies, like the Apothecaries' Society, that are to co-operate with the Medical Council. It would be curious to see the resuscitation of the Apothecaries' Society, with new faculties and a diploma of moderate cost, superseding the more pretentious and costly parchments of the Royal Colleges. This is evidently one object of the Bill, or of Clause V., under which indeed we may have a great development and transformation of the rival system which now obtains and which is a scandal. In the absence of the Medical Council, which seems to have gone to sleep, this clause will probably receive the attention of the corporations.

Annotations.

"Ne quid nimis."

CONVOCATION OF THE UNIVERSITY OF LONDON.

ALTHOUGH the agenda paper of the annual meeting of Convocation on the 11th inst. was very full, the actual amount of business transacted was small. The most important subject—viz., the report of Mr. Magnus's committee upon a new scheme for the constitution of the University—was by leave withdrawn from presentation at this meeting, to be considered at a special meeting on the 25th inst. Certain resolutions affecting the constitution of the University, which were down in the names of Mr. Tyler and Mr. Spratling respectively, were also postponed, it being understood that they would be taken in the form of amendments to Mr. Magnus's scheme. Much time was occupied in the disposal of these matters, which came on after the House had been sitting about two hours. The proceedings commenced with the reappointment of Mr. Allen, LL.B., as clerk of Convocation, and the passage of a resolution approving of the action of the Annual Committee in forwarding a resolution to Mr. J. R. Storrar expressive of their deep regret at the death of Dr. Storrar, the late chairman of Convocation. The report of the Annual Committee was then received. It was resolved on the motion of Mr. Unwin, seconded by Mr. W. L. Carpenter, that a scientific degree suitable for engineering students should be instituted by the University, and a provisional scheme for this object, which had been drawn up by the Annual Committee, was approved and submitted to the Senate. On a motion by Dr. Benson, seconded by Mr. Kisch, that the regulations for degrees in Laws should be referred to the Annual Committee, an amendment, moved by Mr. Newson, to refer the subject to a special committee of seven, was carried. As, according to the standing orders, the members of the committee should have been nominated forthwith, a motion to suspend the standing order was put and carried, and the nomination deferred to the next meeting of Convocation. Dr. Baines moved that Convocation approve of the movement to celebrate the jubilee of this University, the first Charter of which was dated Nov. 28th, 1836. Mr. Bone seconded the motion, which was opposed by Mr. Hutton, who did not think the Uni-

Digitized by Google

versity would add to its dignity, but that it would detract therefrom, by such a celebration. It had not had fifty years even of teaching, but fifty years of examination, which had ended in a great dispute as to whether they were occupying their proper place as a university or not. After a short discussion, the motion was agreed to; but while discussing the terms of the resolution appointing a committee on the subject, the House was counted out.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

THE exceptionally severe and trying weather that prevailed during the first quarter of this year invests with more than usual interest the Registrar-General's report upon the health of England during that period. It appears that the annual death-rate during the quarter was 22·8 per 1000 of the estimated population, and exceeded by 0·6 the mean rate in the corresponding periods of the ten years 1876-85. These figures imply that between 5000 and 6000 persons died in England and Wales during the quarter who would have survived if the mean death-rate had not been exceeded. Only twice during the ten years referred to was the death-rate in the first quarter of the year higher than in the three months ending March last; it was 23·4 in 1876 and 24·9 in 1879. The lowest rate in the first quarter of any year on record was 19·5 in 1884. The excess in the death-rate last quarter mainly occurred in the rural districts. The death-rate in the 17,000,000 of persons living in the chief towns was 23·6 per 1000, whereas in the 11,000,000 living in the small towns and rural districts it did not exceed 21·6. Compared with the average rates in the first quarters of the preceding ten years, however, the excess of mortality in the rural rate last quarter was equal to 5·2 per cent., while it was but 0·4 per cent. in the chief towns. This may be partly due to the larger proportion of elderly persons in the rural population, upon whose mortality the effect of cold is most marked; it may, however, be in large measure attributed to the greater decline in recent years of urban compared with rural mortality, the result of improved sanitary condition. To this general improvement in the national health may, indeed, be attributed the apparently small excess in the general mortality in England last quarter, when compared with the mean mortality in the ten preceding corresponding quarters. During last quarter the temperature fell below the freezing-point of water on 51 of the 90 days: on 16 days in January, 17 in February, and 18 in March. The lowest reading of the thermometer on these 51 days showed a daily average of 5 degrees of frost. In the mild first quarter of 1884, when the death-rate did not exceed 19·4 per 1000, there were only 10 frosty days, with an average of 2·2 degrees of frost. The greatest amounts of cold in the first quarter of any of the 16 years 1870-85, measured in this manner, occurred in 1879 and 1881. In 1879 there were 49 frosty days, with an average of 3·8 degrees of frost; and in 1881 there were 40 frosty days, with an average of 7·0 degrees of frost. The English death-rate was 24·9 in the first quarter of 1879, and only 21·5 in the same period of 1881. It is evident, therefore, that the mere amount of cold does not afford a satisfactory explanation of the wide variations in winter mortality. It is worthy of note that during last quarter the death-rate in the twenty-eight large English towns showed comparatively little excess until nearly the end of February, notwithstanding the 16 frosty days in January and the 7 in the first half of February. The death-rate in these towns averaged only 23·5 per 1000 in the first eight weeks of the quarter, whereas the mean rate in the next four weeks was 27·6. It would appear that cold in March is much more fatal than in January, but far too little is yet known of the conditions which govern the widely varying effect of cold upon mortality.

LIGATURE OF ARTERIES IN CONTINUITY.

CERTAINLY the paper communicated by Messrs. Ballance and W. Edmunds to the Royal Medical and Chirurgical Society on the Ligature of the Larger Arteries in their Continuity was one of the most important of the present session. Perhaps its chief interest lay in the careful and extensive pathological investigation, but it has an evident direct bearing on surgical practice which could not fail to excite the interest and close attention of the surgeons present. The chief contention of the authors was that it is "neither necessary nor advisable" to ligature the vessel so tightly as to rupture the coats. It is necessary, however, to obliterate as nearly as possible the lumen of the artery. The object aimed at should be the excitement of just sufficient damage to cause a chronic or subacute arteritis, which leads to permanent occlusion of the vessel. The internal coats should not be ruptured for fear of opening up channels for septic absorption, and with a view to preventing such a degree of damage as would be followed by ulceration and subsequent danger from secondary hæmorrhage. If it were easily possible to excite just sufficient inflammation to secure the object in view by the means advocated, considerable progress would be made in arterial surgery. Mr. Savory, Mr. Holmes, and others appeared to doubt the possibility of obtaining the desired end by the method recommended when applied to the human subject. An examination of the specimens, both macroscopically and microscopically, which the authors brought forward, is amply sufficient to convince the most sceptical that the means employed in sheep and horses were adequate to the end in view. But here comes the rub. Can we argue from animal to man—from the arteries of sheep and horses to those of human beings? Theoretically we do not perceive why this should be impossible; but even the authors of the paper would probably admit that this is a question which must be submitted to the test of a prolonged experience in the operating-theatre and wards of hospitals for human beings. One point on which the authors commented was the undesirability of attempting to rupture the internal coats of diseased arteries when these have to be deligated in their continuity. Every surgeon must feel the immense importance of the question; for assuredly a benefit of no mean order would be conferred on individuals with diseased arteries if a ligature could be so applied as to be sufficient to incite an inflammatory process adequate to effect the occlusion of the lumen of a diseased artery, and without being so firmly tied as to rupture its internal coats.

MEDICAL STUDENTS AND INFECTIOUS DISEASES.

MEDICAL students in London have for some time been unfortunate in regard to their opportunities for studying acute infectious diseases. The hospitals of the Metropolitan Asylums Board, which are the chief institutions where these studies could be most successfully prosecuted, have been closed against them; but the Managers have at length learned that the public must eventually suffer from the inability of the profession to properly exercise duties which require an intimate acquaintance with infectious disease unless facility is given for their study, and they have therefore put themselves in communication with the Local Government Board with a view to the valuable material their hospitals contain being made available for educational purposes. The Local Government Board have, in reply, pointed out that the section of the Act of Parliament authorising the Managers' hospitals to be used for clinical instruction has been repealed. At a meeting of the Managers held on Saturday, it was resolved that the several infectious disease hospitals under their control should be made available for this purpose, and that the Local Government Board be

Digitized by Google

urged to obtain from Parliament all the necessary powers. Medical knowledge would probably gain much if the boards of management of other Poor-law institutions would follow the example thus set them. Charcot has shown how much may be learnt from a study of the chronic diseases which especially find their way into institutions which are provided for the old and infirm; in London there is a vast wealth of material for study, but which is left untouched, mainly owing to the absence of the use for educational purposes of the institutions containing it. The decision of the Metropolitan Asylums Board may lead to this being better understood.

PATHOLOGY IN THE BIRMINGHAM SCHOOL.

AT the opening of the Summer Session the Rev. W. H. Poulton, the warden of Queen's College, announced that the Council had, at considerable expense, organised a special department for pathological research and tuition. The local institutions have always been rich in morbid specimens, and for some years a distinguished young pathologist has been a member of the resident staff at the General Hospital; but the systematisation of the study of morbid anatomy has been a recognised want in the local school. It has now been supplied by the appointment of Professor Gilbert Barling, who has organised the new pathological department in a very complete manner. The lectures will be given at stated hours in the laboratory, which, for purposes of study and original research, is fitted with stands for thirty students. Microscopes, reagents, and sections are provided for them, and the Professor will be assisted by the medical tutor, Dr. Hogben. The summer course will include anomalies in the distribution of the blood within the vessels; retrogressive disturbances of nutrition, hypertrophy, hyperplasia, inflammation, tumours, and the infective granulomata. A general description will be given of the schizomycetes, and practical classes arranged for pathological study of matters directly related to clinical work. Altogether, the new pathological department at Queen's College, Birmingham, marks a distinct and very important advance.

THE GORDON BOYS' HOME.

WE have much satisfaction in recording the successful establishment and progress, as a part of our national work, of the Boys' Home, which recalls the memory of the late General Gordon. The memorial could hardly have taken a form of greater public usefulness, or one more harmonious with the wishes, the character, and the whole life and actions of the unpretending hero of Khartoum. If there is anything in the history of General Gordon which more than another impresses the reader, it is his singular fitness in emergencies—his appropriateness, we may say, to some of the most critical needs of his time. We seem to notice the same quality in the lives of other great men, in all such more or less, but in none perhaps in so remarkable a degree. Wherever Gordon was needed, he was found; wherever found, his influence was felt and was fruitful of benefit. Whether in China, fortifying the only available form of law and order, and giving direction to the future of that empire which we cannot now estimate; in the Soudan, maintaining justice, promoting the love of liberty, protecting the helpless; or at home, employing his leisure obscurely and wisely for the most neglected of his own countrymen,—he was instinctively and essentially the man for the work. He has been spoken of as a fatalist, though he always repudiated the term. Some belief in destiny no doubt he had, but this did not imply the blind sense of a future which for him was aimless, but a perception of the design and working of a Higher Power with whom he sought to act. It is not therefore surprising that Gordon found his own place in that design. It is to our mind peculiarly characteristic of the man, and suitable in his memorial, that it should have accurately met one of the greatest social necessities of our time. The potential future of a nation is in its young men. Upon their type, their tendencies, and belief its course will chiefly depend. Upon them necessarily also the forces of any time, its perplexities, temptations, and responsibilities will chiefly act; and nothing could be more desirable than that the name and principles of this later Bayard should be perpetuated in an effort to secure the best interests of his young fellow-countrymen. We therefore commend most heartily to public consideration the memorial scheme, which is under the presidency of His Royal Highness the Prince of Wales.

EFFECT OF BITTERS ON DIGESTION.

DR. CHELTSOFF, chief of Professor Botkin's clinic, thinks that extracts of the so-called "pure bitters," which are usually prescribed with the view of stimulating the secretion of gastric juice and of aiding digestion, so far from having any beneficial effect of that kind, are absolutely injurious, inasmuch as they retard the digestive functions. He has made a series of experiments with extracts of aurantium, gentian, trifolium, absinthium, calumba, cascarilla, and quassia on (1) gastric digestion, and the secretion of gastric juice; (2) pancreatic digestion and the secretion of pancreatic juice; (3) the secretion of bile; (4) fermentation; and (5) nitrogenous metamorphosis. The conclusions at which he arrived were that bitter extracts, even in small doses, interfere with artificial gastric digestion, and also with the gastric digestion of animals, but not to so great an extent. Large doses of bitter extracts diminish the secretion of gastric juice, though small doses effect a slight and transitory increase of it, the digestive power of the fluid being, however, in all cases diminished. Bitter extracts have no effect on the secretion of pancreatic fluid, but they nevertheless retard hypogastric digestion. The action of bitter extracts on the secretion of bile is various; extract of absinthium, extract of trifolium, and large doses of extract of cetrarin, slightly increases it, usually at least, but not invariably; while extract of quassia, extract of calumba, and small doses of extract of cetrarin, have no effect at all. Bitter extracts have no anti-fermentative effect, and do not hinder suppuration. Lastly, assimilation of nitrogenous substances is diminished by the use of these extracts.

BULLETINS AND PARAGRAPHS.

IT is only natural that there should be public announcements of the illnesses which befall prominent members of society. Nor is there anything to complain of in the issue of such notifications. More than this, no possible objection can exist to the signing of bulletins by medical men, when it is a matter of moment that the opinion expressed should be promulgated on the authority of the practitioners in charge of the case. The objections we have from time to time urged against newspaper intimations as to the state and treatment of sick personages have been based on particular grounds. Either the announcements have been needlessly issued or they have been of the nature of advertisements, or they have been so drawn up as to be unintelligible or misleading. Speaking generally, we see many and grave reasons why "paragraphs" which are not bulletins should be issued at all. In any case we do not think they should contain the names of practitioners of medicine. If bulletins are needed, let them be written by the medical men in attendance and signed by them. Paragraphs which announce that a distinguished person has been treated by So-and-so, successfully or otherwise, are objectionable in the highest degree. It is enough for the information of the

Digitized by Google

public that the fact of progress, or, in the case of an operation, of success, should be intimated. The introduction of the name of the attendant or operator cannot possibly have other than one purpose—namely, the glorification of the individual named. With reference to a recent announcement to the effect that a distinguished member of the judicial bench had been successfully operated upon by two surgeons simultaneously, the form of the notice would in itself be sufficient proof that the paragraph was not indited by a professional hand. We are, however, in a position to state that the notice in question was issued without the knowledge of the surgeons named.

THE LORD CHIEF JUSTICE AND UNQUALIFIED ASSISTANTS.

THE remarks of the Lord Chief Justice in the trial, at the Central Criminal Court recently, of Mr. A. W. Head, who was charged with the manslaughter of Henry Hibbert, are of a character to be pondered, if we may not question them. He declined to define culpable neglect. He said that the question of being a licentiate of a College or not, having a qualification or not, was a point of difference of which the law of England took no notice in respect of the question of competent skill. So much the worse, we say, for the law of England. The Lord Chief Justice further observed that the very fact that Dr. Money had employed his assistant was evidence of the assistant's competence—"otherwise Dr. Money would not have employed him." This is the most extraordinary deliverance on the subject of medical qualification which we remember to have heard. It seems to dispose of the necessity of all medical authorities and examining boards, and to frank all unqualified assistants acting under the ægis of medical men. After such remarks, we are prepared to find the Judge very tender in his judgment of Mr. Head. Fatty heart was difficult of diagnosis even to the skilled physician; and although the defendant did not verbally correct the erroneous instructions about the medicine, he wrote a label in the plainest hand. It was not necessary to maintain that the defendant had brought the highest skill to the case. All that was necessary was that he should have brought reasonable skill. After such deliverances the jury of course found a verdict of "Not guilty," and the defendant was discharged. The defendant is to be congratulated on having such a statement of the law of competence and skill, not only from the judgment-seat, but from the Lord Chief Justice of England. We will not pretend to be satisfied with it, or to think it satisfactory in the public interest; but the law generally, and that regulating medical practice, is so bad all round, that possibly the Lord Chief Justice's judgment may be justified.

CONNEXION BETWEEN SPLENIC TUMOUR AND THE UTERINE FUNCTIONS.

DR. SKORCZEWSKI describes in the *Przeglad Lekarski*, a Polish medical journal, a peculiar case of splenic tumour which had a distinct relation to the generative organs. A woman aged twenty-six, after a difficult labour four years ago, experienced pain in the left hypochondrium, and in the course of a few days noticed a tumour in the abdomen, which rapidly attained to the size it was when first seen by Dr. Skorczewski. It then occupied nearly the whole abdomen, being of an ovoid form, the long axis being transverse. It was hard, with smooth thick edges, and could be displaced upwards to the extent of a hand's-breadth above the symphysis pubis. The urine was normal; also the number of blood-corpuscles. Quinine and arsenic produced no effect. Electricity was then tried, and after a course of the interrupted followed by another of the constant current, occupying together some three weeks, the tumour had diminished so much that when pushed up under the left ribs it only extended about a hand's-breadth below them. The patient's general condition, too, had become decidedly better. Menstruation, lasting four days, then occurred, and simultaneously the tumour again increased to its original dimensions, and the woman's general condition became worse. Neither electricity nor other methods of treatment which were tried produced any fresh diminution in the tumour or any improvement in the general condition. The connexion between the splenic tumour and the functions of the generative organs was evident enough, but no explanation of this connexion seems to have suggested itself to the author.

HER MAJESTY'S INSPECTOR OF VIVISECTION.

THE announcement of the appointment by the Home Secretary of Mr. J. Eric Erichsen, F.R.S., to the post of Her Majesty's Inspector of Vivisection, under the provisions of the "Cruelty to Animals Act" of 1876, affords a fitting opportunity for an expression of regret that the country should lose through ill-health the services of one who for the past ten years has discharged the duties with a carefulness, highmindedness, and right feeling which those who know Mr. Busk best can most fully appreciate. Her Majesty's Inspector of Vivisection is one of those official personages on whom the public light shines sometimes fiercely, and his relations with the medical profession are both useful and important, requiring the exercise of some diplomacy. That vivisection is necessary for the progress of science we have always held; that it should be guided and directed by those best competent to judge of the value of proposed investigations we equally regard as just in the cause of humanity. In Mr. Busk the Government had, in combination with the Association for the Advancement of Scientific Medicine by Research, two advisers on whose judgment it could rely in carrying out the spirit of the law. It appears from Mr. Busk's report for the past year that of the 53 persons who held licences in England and Scotland during any part of the year 44 performed experiments. The total number of experiments performed was about 800. Of these 210 were done under the restrictions of the licence alone, and 82 lecture demonstrations under similar restrictions, but also under certificates permitting experiments in illustration to lectures, anæsthetics being necessary; 382 were performed under special certificates for experiments without anæsthetics, and 128 under certificates dispensing with the obligation to kill the animal before recovering from anæsthesia. Of the large number (382) performed without anæsthetics, no fewer than 328 consisted, so far as any operative proceeding was concerned, in simple inoculation or hypodermic injection, either with some morbific virus or for the purpose of therapeutic inquiry, and in which the administration of an anæsthetic, to which all animals have a great repugnance, would only entail needless annoyance and distress.

SHOP SEATS FOR COUNTER-SERVERS.

IT has been suggested by the *St. James's Gazette*, and we warmly support the proposal, that a clause should be introduced into Sir John Lubbock's Bill to compel shopkeepers to provide seats for their *employés*. Something more than this is needed—namely, that they should be further required to sanction the use of the seats when provided. As a matter of fact, we have reason to believe that the objection to provide seats pales into insignificance beside the objection to shop-assistants sitting. Both shopkeepers and customers look upon the fact of a young man or woman sitting as a proof of laziness. While this feeling exists it is in vain to contend about seats.

ROYAL MEDICAL BENEVOLENT SOCIETY.

THE twenty-third festival of the Royal Medical Benevolent College took place on Tuesday evening in the Venetian Chamber of the Holborn Restaurant, Sir Andrew Clark, Bart., occupying the chair. The gathering was a large one, about a hundred medical men and laymen being present, and was fairly representative of the various branches of the profession. The Chairman proposed in graceful terms "The health of the Queen," dwelling on the importance of preserving a spirit of loyalty amongst all classes. Dr. E. Waters, of Chester, proposed "The Army, Navy, and Reserved Forces," to which General Sir L. Pelly, M.P., and Admiral Sir Anthony Hoskins replied. The latter mentioned that Dr. Walter Dickson (who was present) and himself started on their first voyage in the same ship many years ago. The toast of "The Reserved Forces" was acknowleged by Dr. Trend, of Southampton. The toast of the evening was proposed by the Chairman, who entered into the details of the working of the institution at some length. In connexion with it are fifty pensioners, twenty-four of whom reside in the College, and are between sixty and eighty years of age; the remaining twenty-six live at their own homes. The school contains fifty foundation scholars, the orphans of medical men, who are lodged, boarded, clothed, and educated. There are, besides, 150 resident scholars, mostly the sons of medical men, who pay nearly enough to cover their expenses; and, in addition, a few day scholars are received from the neighbourhood. Whenever vacancies occur there are a great number of applicants to fill them. The Chairman stated that he believed the work of the institution was exceptionally well done. The total cost per annum was £5000, to meet which they had an income, steadily diminishing, of £3800; a special effort was therefore necessary. Of the 16,000 members of the medical profession, he regretted to say not more than one-fifth interested themselves in the College. This was, he said emphatically, a disgrace both to the successful and the unsuccessful members of the medical profession; and he trusted that this stigma would be speedily obliterated. Subscriptions were subsequently announced amounting to about £4000. The toasts of "The Chairman," "The Head Master,' and "The Honorary Local Secretaries" were then honoured. The proceedings were much enlivened by a well-chosen selection of music interspersed between the toasts. This consisted of choruses and solos from "The Pinafore," and two part-songs, "Integer Vitæ" and "Beware." Mr. Trelawney Cobham, Dr. Lavies, Mr. J. W. Y. H. Lavies, and Mr. G. Anderson Critchett were most successful in their songs, and Mr. W. Ganz presided with his well-known skill at the piano. The arrangements for the dinner were in every way satisfactory. We may add that the annual voting papers for pensionerships and scholarships in the College have just been issued to the subscribers, from which it appears that there are three vacancies for pensioners and twenty-three candidates, only three of whom have been subscribers; there are two vacancies for scholarships and fifty-seven candidates, only two of whom have been subscribers. When will the great advantages of this excellent institution be better appreciated by the profession?

PIPE v. BRICK SEWERS.

FOR some time past we have heard complaints as to the construction of brick sewers in various portions of Paddington instead of the more economical and, under the special circumstances we are considering, the more efficient method of laying down glazed pipe sewers. Thus we are informed that for some four to nine houses in one street a brick sewer 3 ft. 9 in. by 2 ft. 6 in. has been constructed, and Mr. Mark Judge, in bringing the matter prominently before the inhabitants of the parish, points to this as involving a useless expenditure, and he reminds those whom he addresses of the well-known axiom of sanitary science that sewers should be as small as possible, having due regard to the work they have to do. This, we have generally understood, was universally accepted as a rule in connexion with sewer construction. If a sewer is larger than is necessary, the tendency is to reduce the rapidity of the flow of sewage, to favour the deposit of contents, and so to lead to decomposition and the resulting foul effluvia from the ventilators. On this ground alone it is to be hoped that those who ask the vestry to hold their hands in this matter will receive a favourable hearing, and that the practice heretofore in vogue, of building large brick culverts where small glazed-pipe sewers would apparently suffice, will not be continued without some formal explanation of the circumstances which are regarded as justifying it.

HOW DOES NITROUS OXIDE ACT?

THE dictum of Claude Bernard that nitrous oxide does not cause anæsthesia as the result of asphyxia, but by an altogether different mechanism, was accepted as the basis of an interesting and careful paper read by Dr. Dudley Buxton before the Odontological Society of Great Britain. It is suggested that nitrous oxide may be taken as in all probability entering the blood by forming a loose combination with either the oxyhæmoglobin or the globulins and other albuminous bodies. It then passes to the nervous centres and gives rise to subjective exhilaration, acting in fact as a stimulant. If an individual be watched whilst in the act of inhaling nitrous oxide, it will be found, urges Dr. Buxton that the respirations are simply an exaggeration of the normal—quite regular, but hurried in rhythm and increased in depth. There is nothing in the nature of the expiratory convulsions with which one is so familiar in the case of the lower animals dying from asphyxia. The author maintained that he narcotised his patients before the oxygen was exhausted—and, he submitted, a long while before.

"HYSTERICAL FEVER."

SINCE the application of the thermometer to the study of disease, the question of animal heat has assumed an importance that it did not possess before; but at the present time physiologists are not quite agreed as to the mechanism by which its production is governed, and several points require elucidation in considering the production and regulation of the normal heat of the body before we can take the work of the physiologist and utilise it for the study of medicine. The physiologist, however, often receives aid in his studies from the pathologist—the experiments of nature throw light on the experiments of the laboratory. Thus the work of the physiologist brought him to think that the production of animal heat is under the control of the central nervous system in much the same way as its regulation, but the exact proof of this position is wanting. Pathology, however, steps in and supplies the want. It says there is a disease consisting in a functional disturbance of the nervous system accompanied by an increase of temperature. Several cases of this sort have been recorded—viz., of hysteria with a high temperature, the latest of which was a case related by Dr. Debove to the Société Médicale des Hôpitaux, in which the patient, having been under observation for some time, had exhibited, besides her neurosis, occasional elevations of temperature. In the month of November of last year this elevation became continuous, and 39·5° C. was recorded in the axilla night and morning; during December 40° C. was the number, and during the latter part of the month 41° C.; during January, up till the 24th day of the month the thermometer was

Digitized by Google

always above 41° C., and then it gradually sank to the normal by the 29th day. No lesions of the internal viscera could be discovered, but each evening about seven o'clock an hysterical attack came on, which lasted till one o'clock in the morning. But perhaps the most remarkable feature of the case was the slightness or general absence of difference between the morning and evening records. Anyone glancing at the numbers would perceive that this was no ordinary record of disease temperature, and perhaps it will be well to bear this in mind, because it is very easy to see what a dangerous weapon we are introducing into practice when we use the term "hysterical fever." Many are the elevations of temperature for which it is very hard to find an adequate cause, and to comfortably sink back on such a term for these cases would be most disastrous. After this three months' elevation of temperature the convalescence was as rapid as the fall, which tends to show, as Dr. Debove points out, that hyperthermia in itself is not such a source of danger as some think, and that increased heat will not by itself produce lesions in internal organs. A further lesson we may learn from the case, that the differential diagnosis between epilepsy and hystero-epilepsy by the temperature, as pointed out by Charcot, is not absolute.

SIR DYCE DUCKWORTH.

WE understand that Dr. Dyce Duckworth, Treasurer of the Royal College of Physicians of London, and Chairman of the Building Committee of the new Examination Hall of the Colleges of Physicians and Surgeons, the foundation-stone of which was recently laid by Her Majesty the Queen, has received the honour of knighthood. We offer our hearty congratulations to Sir Dyce Duckworth on the honour which has come to him. He is a distinguished medical graduate of the Edinburgh University; he has done much good work in pathology, medicine, and medical literature. His general character for sound judgment and good-heartedness, and his many-sided relations to the profession and to its leading corporations, make the honour conferred on him a matter of satisfaction to the profession. For the same reasons we feel glad that Sir Dyce Duckworth has been charged with the honourable duty of representing the College of Physicians of London in the Medical Council.

A PRECURSOR OF PASTEUR.

AN interesting volume might be compiled under the title of "Medicine's forgotten Worthies," in which few chapters would be more attractive than one devoted to Dr. Eusebio Valli, a Tuscan physician, who died seventy years ago. He was born in 1755 at Casciana, and his first professional laurels were won at Smyrna during a visitation of the plague. We next hear of him in France, where he held a post on the medical staff of the "Cablys" regiment, with which he sailed to Hindostan in 1783. Six years thereafter he returned to Italy, where he was associated intimately, as friend and coadjutor, with the great Alessandro Volta. Then he was appointed to the chair of Clinical Medicine in Mantua, whence he repaired in 1803 to Constantinople, again to study the plague, which was decimating the inhabitants. After its cessation he was once more in Italy and in Mantua, where he resumed his clinical prelections; and next we find him accompanying the French arms to Dalmatia. Thence he journeyed to Spain, and finally to America, where for the third time he encountered the plague, to which, however, he fell a victim on Sept. 24th, 1816. Among his writings is a most instructive account of the "Plague in Constantinople," in which he makes incidentally the following observations:—"When at Leghorn, in 1790, I communicated rabies to several animals by inoculating them with saliva taken from a hydrophobic dog. Inoculating other animals with the same saliva, corrected with the gastric juice of the frog, I found that none of them contracted rabies. Then I treated with this same gastric juice the son of the widow Rosselmini of Pisa and a maid-servant of the household, both of whom had been bitten by a foxhound which was suffering from hydrophobia. This inoculation neutralised the poison, and by the same means I cured a case of snake-bite, and also modified the variolous contagium, so as to generate a malady without cutaneous eruption, non-malignant and free from danger." This curious passage would have been lost to the historian of medicine but for the duteous care of the Cavaliere Giuseppe Valli of Ponsacco, a descendant of Dr. Eusebio Valli, who, after much research, compiled from documents unpublished or forgotten an interesting memoir of the Tuscan physician, which first saw the light in 1881. An appreciative review of this work appeared in our contemporary *Lo Sperimentale* of Florence, from the pen of its conductor, Dr. Angelini Filippi, and attention has again been drawn by the Tuscan school to Valli's treatment of hydrophobia by counteractive inoculation as a remarkable episode in the series of experiments which have culminated in the method of M. Pasteur.

PTOMAINE IN CHEESE.

IN the course of the year 1884 more than three hundred individuals inhabiting the State of Michigan experienced symptoms of poisoning after having partaken of a certain kind of cheese. In many of them the symptoms were of grave import, the medical attendants seriously discussing the possibility of poisoning by such irritants as arsenic, and indeed, prescribing the hydrated oxide of iron on that view. Vomiting, first of aqueous fluids, afterwards tinged with blood, was accompanied by severe diarrhœa. Constriction about the throat, epigastric pains, white fur on the tongue, soft irregular pulse, and cyanosed face were also observed. Fortunately none of the cases terminated fatally. The cheese examined by M. Vaughan had nothing peculiar in its taste or odour. On a fresh section numerous drops of a feebly opalescent liquid were to be seen, and micrococci existed in abundance in it. An alkaloid was extracted from the solid part of the cheese. Placed upon the tongue, it imparted an acid and burning sensation, soon followed by dryness of the throat and nausea. Absorbed in small quantity, it caused diarrhœa. M. Vaughan names it "tyrotoxicon," and obtained half a gramme of it from fifteen kilogrammes of cheese.

DUST AND REFUSE NUISANCES.

LONDON is threatened with another dust nuisance, for a wharf has been secured off Fermoy-road in the parish of Paddington, and the dust of Chelsea is to be removed there for the purposes of being sifted. The ratepayers in the neighbourhood very properly declare that if any dusting business is to be carried on in this populous district, it will soon become a nuisance and be dangerous to public health; and, in view of the importance of the subject, a special effort was made at the last meeting of the Paddington vestry to bring the matter forward. But the vestry adjourned for three weeks! A correspondent in the *Daily News* again asks the question why London householders should not follow the example set them in Paris, and place their house refuse every night in the street, whence it is easily removed in the early morning by the proper authorities. We presume the answer is to be found in the influence which dust contractors can bring to bear upon our local authorities; dust removal is now subject to a trades interest; at some times of the year it answers the contractor's purpose to remove house refuse, at others he has no immediate use for the dustbin's contents, and neglects to carry out the duty he is paid to perform. Doubtless.

Digitized by Google

if the removal of refuse were regarded only from the public health point of view, it would be found a more economic method to fill the dust-cart as rapidly as possible, and for this purpose the regular and systematic call for the refuse of every house would enable this to be accomplished much more readily than if the dustman were to continue, as at present, to make his irregular perambulation through the streets and only assist those householders who may chance to hear his cry, and be willing and able to submit to the blackmail which he levies as if by right.

SANITARY WORK IN ST. LUKE'S.

A CASE recently heard by Mr. Barstow at the Clerkenwell Police-court gives evidence of the need for the active enforcement of the provisions of the Sanitary Acts in the parish of St. Luke's. A summons had been taken out against the owner of premises known as the City of London Baths, Golden-lane, which had been converted into dwellings for poor people. Dr. Yarrow, the medical officer of health, gave a pitiful account of the condition of these buildings. There were, he said, within them twenty-three closets in a dirty state, all without water-supply; twenty-five rooms which were dirty and required whitewashing; some of the drains were stopped, while others were open; in the basement were two or three hundred cartloads of the most offensive refuse; ashes, instead of being deposited in bins, of which there were none, were heaped in many cases on the stairs. Dr. Yarrow asked for the premises to be closed, a request with which Mr. Barstow complied; the new Chatham-garden-buildings had been erected near, and the people, occupying the "Baths" could easily obtain at a low price the necessary accommodation. While we may express our satisfaction at the termination of conditions so disgraceful, we are none the less led to wonder how any premises could have been so neglected. Two or three hundred cartloads of offensive material cannot have accumulated in a brief space of time. We are forced to the conclusion that either the inspectorial staff is insufficient or that the vestry have been unwilling to comply with the recommendations of their officers. We trust that Dr. Yarrow, who has not long been appointed, will be able to reorganise the sanitary administration of this thickly populated parish.

THE VALUE OF A POST-MORTEM EXAMINATION.

AN adjourned inquest was held at the Town Hall, Hull, on May 6th, touching the death of Ellen Jane Jackson, a married woman. It appears that deceased some five weeks after her confinement—from which she had recovered—was seized with pain in the lower part of the abdomen, and that Mr. Swarbrick, an unqualified medical man, was called in to attend her. In the opinion of the latter the case was one of obstruction of the bowels, and, acting upon his diagnosis, he administered croton oil as a purgative. Subsequently the symptoms became more alarming, so much so, in fact, that it seemed clear that peritonitis had supervened. To alleviate this Mr. Swarbrick ordered opium and calomel, but in spite of this Mrs. Jackson died. Prior to her death she expressed her belief that Mr. Swarbrick's treatment was at fault; in fact, she went so far as to say that that gentleman had murdered her. The allegation was repeated by the husband, and this, strengthened by statements made by Dr. W. Ballingall, who was called to see deceased shortly before her death, that "there are symptoms of irritant poisoning," and "the cause of death is dark and mysterious," caused the coroner to order an inquiry, although Mr. Swarbrick had issued a certificate of death. This certificate bore the signature "Charles Eyre Councillor," a qualified medical man with whom Mr. Swarbrick had up to May 1st acted as partner or assistant. During the hearing of the case it transpired that Mr. Swarbrick possessed blank certificates of death signed by Dr. Councillor; but the particular one in question, although it bore Dr. Councillor's name, seems to have been signed by Mr. Swarbrick. The post-mortem examination was conducted by independent medical men. It revealed acute inflammation of the right ovary, with consequent peritonitis. From the appearances observed the medical witnesses could not say that the treatment had accelerated death, nor that other modes of treatment would have succeeded in saving Mrs. Jackson's life. The jury upon this returned a verdict that death resulted from peritonitis. Assuming that the exact nature of the affection could have been diagnosed, it would certainly not have been appropriate to administer strong purgatives; but the difficulty in making out the exact primary lesion in the presence of peritonitis is always great. The peritonitis itself would cause constipation, and this might lead to the supposition that the case was one of obstruction of the bowels. Such mistakes are not infrequent. It was not shown that Mr. Swarbrick had been guilty of carelessness, much less of culpable negligence. We are therefore satisfied that the finding of the jury was an equitable one. Nevertheless, we must express our disapproval of the practice, which unfortunately is too common, of unqualified medical men attending patients and giving death certificates bearing the signature, or what appears to be the signature, of a qualified medical man who has never seen the case at all. In the present instance it appears that Mr. Swarbrick signed the certificate in Dr. Councillor's name; but in extenuation of the irregularity, it must be allowed that there was an inducement in the fact that he had previously been in possession of blank certificates—ready for filling-in,—which bore the real signature of Dr. Councillor.

THE CHOLERA IN ITALY.

DURING the week ending May 12th cholera has continued to prevail in Italy, and it has unfortunately enlarged its area of distribution. In the town and province of Brindisi 52 fresh cases and 18 more deaths have taken place, the disease showing some tendency to diminution during the past two days of the week. But the port town of Bari, situated some seventy miles higher up the Adriatic coast, has also become infected, the fresh attacks and deaths notified as having occurred during the two days May 9th and 10th reaching 61 and 21 respectively. No fresh news as to the prevalence of the disease at Vicenza has come to hand since May 5th, when two cases and three deaths were announced as having occurred on that and on the preceding day. But in the city of Venice fresh cases and fatal attacks are steadily maintained, the former varying daily from 9 to 13 and the latter from 3 to 8. In all, 62 cases and 25 deaths were reported as having occurred during the week.

HEALTH AND ATHLETICS.

IT would be superfluous to state that athletes are generally, as they ought to be, the healthiest of mankind. This is the rule, and it follows that deaths incurred by athletic exercise are usually the result of accidents which may with due care be avoided. There are exceptions, however, and among such must be numbered a young man who is reported to have died suddenly at Rockwell College, Cashel, from heart disease, after winning a race. Such a sad occurrence, though rare, is probably not unique. As we write we can recall a nearly similar instance of sudden death. The moral is obvious, yet it may very possibly pass unheeded by many who would do well to consider it. Athletic men are not prone to trouble themselves with valetudinarian fancies, and we certainly have no idea of intro-

Digitized by Google

ducing them to this unprofitable line of thought. At the same time, it would be well if all such, before inaugurating a course of severe bodily effort, were to assure themselves that no vital flaw entailed a wise abstinence upon them. Boys at school are apt to be wholesomely free in the use of their muscular powers, and gain thereby in strength and resolution far more than they lose by fatigue. Yet it is most necessary that the exceptions among them also should be known and suitably restrained when necessary by their masters. With respect to heart disease, the question of strain is a most important one, especially since the latent weakness may not be apparent under ordinary exertion. It is surely no more than reasonable to make some allowance for an organ which, though unsound, is often capable, if protected from heedless risk, of passing successfully through the work and worry of an ordinarily active life.

POST-MORTEM EXAMINATIONS IN CRIMINAL CASES.

IT is not long since we took occasion to insist upon the desirability, nay, the necessity, of having a thorough post-mortem examination made in all cases where the death might entail a criminal charge. We are glad to find our views have received the judicial sanction and support of Mr. Justice Fitzjames Stephen, who at the present Stafford Assizes took occasion to say, in regard to a charge of wilful murder by shooting, that a post-mortem examination should have been made so that the exact cause of death might have been ascertained and recorded. It is only common fairness to the accused that the medical evidence which may be adduced at the trial should, as far as possible, relate to ascertained facts. Medicine is not an exact science, and many issues of life and death will ever remain enigmatical; but this is just the reason why every endeavour should be made to clearly distinguish between what is certain, what probable, and what possible.

PHOTOGRAPHING THE UTERINE CAVITY.

A SWISS physician describes a plan of introducing wadding tampons and laminaria tents into the uterus, by which he has succeeded in dilating the organ to such an extent as to be able, by means of reflectors, to get a complete view of the whole cavity in cases of carcinoma, fibrous polypi, fibromata, and endometritis. Not being content with ocular inspection, he has also contrived to obtain photographs of the cavity. New inventions for uterine exploration, medication, and instrumentation are often of a somewhat hazardous nature, but we tremble to think of the future of some female patients if photographing the interior of the uterus should ever become one of the medical fashions of the day.

SMALL-POX HOSPITAL PROVISION.

THE Metropolitan Asylums Board are evidently weary of waiting for the consent of the Local Government Board to erect at Gore Farm, Darenth, a new small-pox hospital for convalescent patients. Sir Edmund Currie naturally pointed out at their meeting on Saturday that it was necessary for the Managers to complete their plans before the next epidemic prevalence of this disease, but the difficulty with the Local Government Board is probably less the unwillingness to allow the expenditure of public money than to determine the best method in which this money can be laid out. The aggregation of cases of small-pox has been definitely shown to be attended by disastrous results, and the continued investment of large sums in the same manner as heretofore is not, in face of this evidence, in accordance with common sense. The Managers are without responsible advice in this matter, and will doubtless, if necessary, shelter themselves under this plea, but the Central Board are differently circumstanced in this respect, and will obviously have to adopt some other course than that which has been attended by so many misfortunes. Certainly the fact is very evident that the outside relations of these institutions can no longer be neglected. It is impossible that they should only be thought of as temporary homes for sick persons; their influence upon the public health of the metropolis must be considered in all its details, and for this purpose it is necessary that the question of dealing with small-pox in London should be made the subject of further study, and ample means provided for watching the effects of any action which results from the conclusions to which these Boards may come.

THE LATE DR. AUSTIN FLINT.

THE *New York Medical Record* of April 24th contains a memoir of Dr. Flint by A. Jacobi, M.D., President of the New York Academy of Medicine; also a paper entitled "Reminiscences of Professor Austin Flint." It is natural that the friends and countrymen of the deceased physician should not "let die" his virtues and his work, which leave such a model for future physicians in his and in all countries. Dr. Flint was English in his descent from Thomas Flint, a Puritan, who emigrated from Derbyshire to Concord, Mass., in 1638. His father, grandfather, and great-grandfather were physicians in Massachusetts. On our side, we shall remember Dr. Flint, not only for his English blood, but for his contributions to medicine, his fine form and face, and his genial and frequent visits to us, which we had come to regard as a sort of annual treat.

COMPLETE QUALIFICATIONS FOR COMPLETE EXAMINATIONS.

IF the unsatisfactory Medical Bill of the Government is to be proceeded with, a strong attempt is likely to be made to secure a recognition of the full qualification of those who have been examined in all branches of the profession by any one corporation or university. The idea that a man ought to go to two corporations to pass practically two similar examinations has its origin in consideration for, not the benefit of, the public, but of the corporations. And yet Sir Lyon Playfair proposes virtually to continue this injustice by requiring one corporation to join another, even if its examinations be complete—as, say, in the case of the Royal College of Physicians of London. This is to legalise injustice.

THE HOSPITAL SUNDAY.

IT is to be hoped that the reluctance of one or two hospitals to take an active part in organising local meetings in the week preceding Hospital Sunday will be overcome. Dr. Wakley's proposals have been heartily adopted by the Hospital Sunday Fund, and especially by its most active members. And it would be a pity to see anything like apathy on the part of leading hospitals.

ASEPTIC PREPARATIONS.

SMALL glass capsules, hermetically sealed, according to the *Pharmaceutical Journal*, are coming much into use for the storage and preservation of various fluids. M. Limousin proposes to employ them for keeping solutions for hypodermic use. The capsules, with long capillary tubes, are first sterilised by heating for some time at a temperature of about 200° C., and may then be filled in the ordinary manner, or by injecting with the hypodermic syringe and sealed in the flame of the spirit lamp or Bunsen burner. When required for use, the point is broken and the fluid transferred to the syringe by one slow stroke of the piston.

PROPOSED CHALLENGE SHIELD FOR THE VOLUNTEER MEDICAL STAFF CORPS.

AN effort is being made to raise the sum of £40 for the purpose of obtaining a Challenge Shield for the Volunteer Medical Staff Corps, the trophy to be competed for by the members of the corps, and to be presented to the company that is considered to be most fit to receive it. The shield will be competed for annually, and, although considered as the general property of the corps, will be retained by the company who may have gained it for that year. Should a greater sum be subscribed than is asked for, either a second prize will be given or a more expensive shield than the one now contemplated will be ordered. Subscriptions (which are limited to one guinea each person) to the amount of £21 have already been received.

ITALIAN HOSPITAL AT CONSTANTINOPLE.

Il Morgagni (1st inst.) gives a description of the hospital which was erected in 1876 by the Italian Government in the Tophané quarter of Constantinople. The sum expended was £12,000, and the institution covers an area of 3800 metres facing the sea. The *personnel* consists of two paid medical officers, fourteen sisters of charity, and four male attendants. The chapel is an architectural gem. Public and private wards, lifts, bath-rooms, and a constant supply of fresh and salt water are provided. Paying patients are admitted, with reduced terms for those of Italian nationality. In 1884 the male patients numbered 309; the females, 41; and the deaths 28. An income of about £400 was derived from the paying patients, about one-third of the total expenditure, exclusive of medical attendance. The balance was defrayed by the Italian Ministry of Foreign Affairs. A lunatic asylum, adapted for twenty patients, and the consular prison, adjoin the hospital.

"NO EVIDENCE" OF INSANITY.

IT matters little practically that in a recent case of shooting the plea of insanity was not set up, although the behaviour of the prisoner was so strange that the Lord Chief Justice commented on the fact that no legal evidence had been offered. The accused, on conviction, was sentenced to imprisonment for eighteen months with hard labour, so that he will be under observation. Disastrous results might have occurred had he chanced to be acquitted. It is clearly necessary that something should be done to ensure the consideration of this question of sanity or insanity in every case before a prisoner is arraigned. We hold that the preliminary issue of responsibility ought logically to be already determined when the secondary issue of guilt is raised.

CENTENARIANS.

PROFESSOR HUMPHRY (Cambridge) is engaged in collating for publication the reports which friends have been good enough to send him respecting centenarians; and he will still be glad to forward a form for particulars to any member of the profession who will kindly take the trouble to fill it up from his knowledge of a person who has attained or passed the age of a hundred years.

FOREIGN PROFESSORIAL CHANGES.

PROFESSOR HERMANN EMINGHAUS of Dorpat has accepted the Professorship of Psychological Medicine in Erlangen. Professor Rühle of Bonn, who has just returned from six months' leave in Italy, resumes his lectures during the present summer semester. Dr. R. Hirzel, Extraordinary Professor of Pharmacy in Leipsic, has accepted an appointment at Jena. Professor Sohnke of Jena has been appointed Professor of Physics in Munich. Dr. Adolph Schenkl has been appointed Extraordinary Professor of Ophthalmology in the German Medical Faculty at Prague. This university has to lament the death of Dr. E. Linnemann, Professor of Chemistry. Dr. Ovsyannikoff, who has been for many years Professor of Physiology at the University of St. Petersburg, and was formerly Professor in Kazan, has retired.

HOW TO DETECT ACETONE IN URINE.

IT is stated by Mons. P. Chautard that the presence of acetone in urine or pathological liquids may be readily detected by adding a drop of an aqueous solution of magenta decolourised by sulphurous acid to the suspected liquid, when, if acetone is present, a violet colour is produced, the intensity of which is proportional to the amount present. In dilute solutions the colouration does not appear until after four or five minutes; if the amount of acetone is very minute, the urine or other liquid may be distilled, the first portion that comes over being examined. In this way a very minute proportion of acetone may be detected.

THE next half-yearly dinner of the Aberdeen University Club, London, takes place on Wednesday, the 19th inst., at the Holborn Restaurant. The Right Hon. Lord Watson, formerly M.P. for the University, will preside; and among the guests expected to be present are the Principal (Dr. Geddes), Sir Peter Lumsden, and Sir Donald Stewart.

THE spread of venereal disease amongst the native population and white settlers at the Cape is exciting great attention in the colony, the reports of the district surgeons which were recently laid before the local Parliament containing an appalling account of the ravages of the disease in its most malignant and loathsome forms.

THE ceremony of unveiling the statue by Mr. Brock, A.R.A., of the late Sir Erasmus Wilson, will take place at the Royal Sea-bathing Infirmary, Margate, on Tuesday, the 25th inst., at 1.30 P.M. Sir James Paget, Bart., will present it to the Infirmary on behalf of Lady Wilson.

THE Medical Society of London has awarded the Fothergillian Gold Medal to Dr. Strahan, of Belfast, whose essay is entitled "The Nature and Varieties of the Fevers prevalent in the United Kingdom."

THE deaths are announced of Dr. Nicolai Voronzovski, Professor of Operative Surgery in Moscow, and of Dr. Rud. Monnier, Emeritus Professor of Anatomy in Val-de-Grace.

THE use of calf lymph for vaccination has been made compulsory in the Grand Duchy of Baden, from March 1st.

CITY ORTHOPÆDIC HOSPITAL.—The thirty-fourth anniversary festival of this hospital was held on the 6th inst., the chair being occupied by H.R.H. the Duke of Cambridge. During the past year 2590 cripples have received treatment, and the total number of patients since the charity was established in 1851 is 48,900. The financial condition is highly satisfactory, the receipts having during 1885 exceeded the expenditure by £175. Donations and subscriptions to the amount of £1000 were announced by the secretary.

MR. LE PAGE, a surgeon in Salford, has recovered damages, amounting in the aggregate to £2100, as compensation for injuries and loss sustained by him owing to an accident on the Lancashire and Yorkshire Railway, the particulars of which we gave at the time of its occurrence.

A REVIEW OF THE PRESENT SYSTEM OF MEDICAL EDUCATION IN LONDON.

By W. MOXON, M.D.

I SUPPOSE it will be allowed that education does not exist for the benefit of universities, but universities for the benefit of education. Graduation, the special endowment of universities, exerts a fascinating and powerful attraction in the encouragement of learning. A degree is the thorough student's proper reward. The hope of it is his worthiest ambition. A degree is due to him after he has passed through a sufficient course of methodised study. This truth is universal to universities. What is graduation? This is no idle question, because the true signification of a word may be buried with its derivation, and its proper meaning may be utterly forgotten so as to be denied to the very things which the word was intended to signify, and that at a time when the word is wanted as a just sanction. Surely, the idea involved in graduation is the fixing of steps or grades in a systematic course of learning which the graduate passes through in obedience to rules of method laid down by the degree-giving body or university.

This idea of graduation is no mere play on words, and the meaning of graduation should not be forgotten when a degree such as M.D. Brussels, &c., is given to those who have taken no methodical steps under the governance of the university that gives the degree. At present we witness a strange and most unfair and unjust anomaly. A degree, which properly means a token of graduate progress, is given—say at Brussels—where no steps of progress were prescribed or demanded; and this degree is given for learning which was obtained by a well-ordered system of steps of progress in London, steps prescribed by so-called "colleges" in London which are able to prescribe the steps and ensure the learning, but cannot grant the degree. It is not contended that the learning tested at Brussels is insufficient to justify the degree, and the degree of M.D. Brussels is held to be valid in this country.

In London we have graduation without degrees. The student of medicine in the metropolitan schools is conducted by the Royal Colleges of Physicians and Surgeons through a graduate's course of teaching and of examinations, and he is rewarded with the same title which the father obtained for a tithe of that training which the son has to undergo—a title which no longer suffices for the requirements of general practice. The result is to blight the spread and elevation of medical education in this vast city. Public attention should be concentrated on the causes of this anomaly, so that a flagrant injustice may be swept away. Systematic and graduated education in medicine has developed itself in the curricula of the Royal Colleges. It is now necessary that this should be duly recognised, and that the right of conferring degrees in due proportion to methodised attainments should in a fitting manner be attained by the colleges. Thirty years ago the system of medical instruction in London hospitals was as crude as the system of examination at the Royal Colleges was undeveloped. At that time the student spent, very much as he liked, a period of three years in preparing for an examination for the membership of the College of Surgeons and for the licence of the Apothecaries' Company, the diplomas usually taken. The examination consisted of questioning *vivâ voce* by four examiners, who severally inquired into the candidate's knowledge, each for a period of a quarter of an hour. These quarter-hours spent by the candidate without interval at four successive tables summed up into an hour of more or less equitably agreeable conversation, and the hour's talk thus put together served as the only test of the candidate's fitness for the diploma of the college. It is not fair that the graduated course of instruction and examination now in force should give no better reward than the diploma so obtained thirty years ago.

The old system may perhaps have had some occasionally valuable advantages. It left men of genius to the play of their own energies, so that the man of energetic genius had a freer field. And men of no great general power had three years of comparative quiet all to themselves, in which to gather information, if and when they pleased, in the manner best suited to their particular lines of mental progress, if any. For although lectures had to be signed up, yet attendance was less necessary than signature in the matter of these lectures. To those who approve of freedom in study it might appear that these were the happy days. A man had time to arrange his knowledge into ready accordance with the purposes he must keep in view in the duties of practice. There was leisure for the process of pondering and ascertaining the relative gravity of the considerations he had to undertake. But there is no time for pondering now; indeed, the word has gone almost out of use with the loss of what it signified in more static times. If things had remained as they were thirty years ago, there would be no call for medical degrees from the Royal colleges. But the time of freedom is over. Men are severely trained now at the London medical schools, and they claim their due reward. The whole system has advanced to university proportions. The student is compelled to take in large supplies of science, not for mere direct use and purpose in his vocation, but imparted as means of mental culture. The curriculum is one of utility duly adorned; it amounts to university graduation in all but the title conferred, and now a title is claimed.

Thirty years ago the systems of the Royal Colleges had none of the characters of university training. There was no division into stages, no tutorship, no plan of study pursued step by step under supervision, with examinations to ascertain the thoroughness of the several gradations. There was nothing to give the signification of the term "graduation," and to ensure the developmental soundness of the graduate's progress. But all this is changed, so that at the present day it would be difficult to say what is really the difference between the course of study pursued by the student of a London hospital and the course of study followed by a medical undergraduate at a Cambridge college. There are good and indifferent students at both. Learning is not always thorough at either, but an average man at one or the other has the same things to learn in the same way. It must be remembered, too, that thirty years ago physical science had not any of its present university recognition. It was looked upon as not liberal education. In the last thirty years a great revolution has occurred in the university value of the several branches of learning, so that at Cambridge and elsewhere degrees are obtained almost solely in such sciences as are taught equally well in a parallel systematic course at the London schools of medicine. Thus it is true that not only have the Royal Colleges, with the London medical schools, actually developed in the last thirty years a university system, but in the same period the Cambridge and other university systems have been adopting the same lines as those of the Royal Colleges and London schools. In fact, the so-called Royal Colleges are not colleges; a college is a teaching body; the Royal Colleges are examining bodies, which govern the medical teaching colleges and schools of the metropolis. They are out of kind amongst colleges, much in the same way as the ugly duckling was out of kind amongst proper ducklings.

Is it not simply true that the system of teaching and examination now in force in the medical schools and in the Royal Colleges of Physicians and Surgeons is in fact and in deed a graduated course such as everywhere else leads to the conferment of a degree? A "teaching university" for medicine already exists in London. The teachers of the London schools are practically all of them Fellows of the Royal Colleges. In these Colleges they or their chosen representatives compose to a large extent the deliberative body which acts as a board of studies in that faculty of medicine which the Colleges constitute in fact, though not in name. Either directly, or but little indirectly, the teachers prescribe the lines of study and of examination. The examiners are chosen from amongst their number. Besides those actually engaged in teaching, the deliberative body or board of studies comprises the most experienced and distinguished leaders in medicine and surgery in the metropolis—men whose character has secured, and may be trusted to further ensure, the maintenance of a proper standard of requirement in the examinations. We thus have in the Royal Colleges a university organisation, so far as regards the medical faculty, complete in itself; and the relation of this organisation to the London University is significant. In fact, the examiners in the medical faculty of the London University are practically the very same persons as those who examine at the Royal Colleges, and the same persons as those who teach at the London schools.

Digitized by Google

The *personnel* is practically identical. They are the same persons, scattered in the schools, gathered in the Royal Colleges, and represented as a small minority by a few of their number at the London University. Already, in fact, the course of study and examination at the Royal Colleges represents the Pass degree in London Medical University education, and the London University degree represents the Honours degree. So that it might appear easy to arrange for the required extension of medical graduation in London by some form of union devised to incorporate the Royal Colleges in the existing London University, seeing that the *personnel* of the two institutions as regards the medical faculty is practically identical, and that all are moved by the same aims and interests for the benefit of the study of medicine in London. But those members of this *personnel* who are employed at the London University are subject to the power and tendencies of that University, and in fact their own views and the views of the body of metropolitan medical teachers have no more than a small and fractional influence there.

The London University is not free from the conditions of its origin, which conditions must be kept in mind in considering the services that it fulfils. The object of those who first moved in its formation was to found a teaching university. The original shares—some of them I now hold in hand, they are of no present or prospective pecuniary value—were subscribed in order to make provision of university education for such persons as, not being members of the Church of England, were at that time excluded from privileges at Oxford and Cambridge. The history of this attempt is very instructive. The forces under whose play the project came into action succeeded in completely dividing its issue into two distinct and separate institutions. One of these institutions represented the teaching part of the scheme, and now stands in Gower-street as University College, London; the other institution was the University of London, which represented the degree-giving part of the scheme, and now stands in Burlington-gardens. These two institutions, which are twin offspring of a divided germ, have been borne apart and made more and more separate. History represents tendency. The line of development which the University of London has pursued was determined by the pressure under which it entered into existence. This pressure was weighty. The Universities of Oxford and Cambridge and the College of Surgeons brought all the power they could to suppress it. From 1830 to 1835 the hopes of its parentage were deferred. When at last a body was formed with the requisite privilege and means of granting degrees, that body owed its constitution largely to the hitherto successful opposition of those who had feared easy rival degrees.

Under vast pressure a Senate of great weight had been brought together. One main principle on which this Senate was composed appears to have been of the nature of a guarantee that the Nonconformists did not get their degrees easily. This principle of guarantee led to the elevation and maintenance of a lofty standard of requirement. And though the Charters of 1850, 1858, and 1863 brought some modifications into the growing University, yet the University itself has not only remained under the influence of that Senate of guarantee, but it has achieved exalted distinction in very consequence of the elevation of standard which the high level of examination determined by that Senate has ensured to the degrees conferred by the London University. And now this elevation is the distinctive and unalterable character of the London University degrees. The function of the University has been developing before it in all the phases of its growth. Its progress has been upwards, always demanding more and more attainment in those who would belong to it. Its standard is the edge of the unattainable to ordinary class-men, the wholly unattainable to ordinary pass-men. At some point all ordinary candidates are sure to come to grief. The Senate cannot turn away from the history and lower the character which has brought the University into such repute. The Senate is bound by the requirement which it has itself created, and which it alone can fulfil. This demand is for such a degree as (1) shall be attainable by all English subjects, irrespective of the mode and place of tuition; (2) shall be attained only through a very high standard of acquirement. In the plastic stages of its first origin the embryo University refused local connexion and limitation. It declined to be turned to ordinary uses, such as the use which the Oxford, Cambridge, and other Universities fulfil in giving Pass degrees to men whose academic virtues do not include superior power of answering "stiff" questions. It refused to give degrees as the natural reward of a graduate course to men of ordinary ability, as other universities do. The full-grown London University cannot now localise its wide sphere of operation, nor stoop to common mould. If it lost its universal character and became a town affair, it would wholly forsake the means of its present elevation, and would fall. No friends of the University will take measures that could only issue in restricting its range to the metropolis and lowering its standard to ordinary levels.

Let it be sufficiently understood that the metropolis has within itself, independently of the London University, and already in separate operation and waiting to be combined in common action, all the machinery for a local university. The separate parts want only union, recognition, and a name. With the Royal Colleges of Physicians and Surgeons as a Medical Faculty, with University and King's Colleges as a Faculty of Arts, and with a Faculty of Science developed from the Kensington and Jermyn-street Schools—already there is a Faculty of Music with right of conferring degrees,—why should not an "Albert University" take its place on the Embankment?

THE GERMAN MEDICAL CONGRESS.

(*Continued from p. 896.*)

THE subject of the Pathology and Treatment of Diabetes Mellitus was opened in a paper by Dr. STOCKVIS (Amsterdam), who began by showing that the problems of its etiology had become more complex than was supposed when Claude Bernard discovered the glycogenic function of the liver. Diabetes depends on a deeper disturbance than glycosuria and glycæmia, and its final explanation will not be found until the whole of the nutritive processes of the organisms, its organs, and cells are known. It is due to changes in several organs—at least, in the intestine, liver, and muscles,—and must be regulated by a central organ as yet undetermined. Several points were touched upon. 1. *The relations of diabetes to albuminuria.* The latter is generally considered as due to the increased work thrown upon the kidneys, and is regarded as a late symptom; but Professor Stockvis finds it in all cases in amount proportionate to the severity of the case. Often albumen appears to alternate with sugar, the reason being that, owing to the polyuria, albumen is difficult to detect in the period of severe glycosuria; so that, when both glycosuria and polyuria subside, the albumen seems suddenly to appear. In other cases careful examination is needed to bring the diabetes to light, owing to the predominance of albuminuria. The symptom is not explained by mere variations in blood-pressure in the kidneys, such as are produced in experimental glycosuria. It may depend upon changes in the albumen of the blood, or more probably upon renal changes. Various conditions are described, from simple catarrhal nephritis to the contracted kidney, as well as hyaline degeneration of the secreting epithelium. The glomeruli are probably the regions the denutrition of which gives rise to albuminuria, and the foreign matter circulating in the blood acts as an irritant. Thus acetone, aceto-acetic acid, butyric acid, and grape-sugar, when introduced into the veins, excite albuminuria. Prognostically, albuminuria is by many regarded as a very fatal complication, but Bence Jones considered that it was better to have both diseases together than diabetes or nephritis separately. Two kinds of cases may be distinguished. In the one albuminuria occurs in small degree during glycosuria, and becomes more marked on the disappearance of the latter, and later entirely disappears. This variety is of no consequence. In the second variety the albuminuria, previously marked, persists, and is indicative of nephritis after the disappearance of the diabetes. This occurs in one-third of all cured cases of diabetes; but the renal disease can hardly be considered as the cause of the cure of the diabetes. Treatment is governed by general therapeutic principles, especial attention being directed to strengthen the cardiac power and to regulate digestion. 2. *Diabetic coma* has excited much attention since Kussmaul's writings twelve years ago. Excluding intercurrent

Digitized by Google

diseases, as pneumonia &c. diabetics usually die in one of two ways—(1) with all the phenomena of collapse, slight somnolence, and toxic symptoms, without sweetish odour of the breath, without acetonæmia and diacetonæmia, or (2) with predominance of toxic symptoms. The first form is to be ascribed to cardiac failure, and ought not to be regarded as self-intoxication. In the second form there are always volatile products in the urine—acetone, diacetic acid, &c. This is the special coma diabeticum, with symptoms pointing to profound disturbance of the central nervous system by auto-intoxication. A sudden accumulation of noxious material in the body can only be brought about by its sudden increase, and especially by hindrance to its excretion. Such conditions would occur through nephritis, and therefore in diabetic coma there is invariably albuminuria with all kinds of casts. It is nothing but a special form of uræmia, the differences depending on the special conditions giving rise to them. When large quantities of grape sugar are injected into the blood of animals the breathing is affected as in diabetic coma. These rare cases of coma without albuminuria must be ascribed to a sudden enormous increase of tissue disintegration, which the healthy kidney cannot cope with. Death by coma is more frequent than by bacillary phthisis in diabetes. It favours no age or sex, and occurs equally in so-called severe and slight cases. But when there is marked pulmonary phthisis diabetic coma never occurs. In the first form fatigue plays a great part; the second variety is especially excited by excesses, which derange digestion and promote the formation of abundance of toxic substances. These materials do not depend upon an animal diet, but their precise source is yet undetermined. As to treatment, the first variety calls for cardiac tonics; in the second, or true diabetic coma, although there is no really rational method of dealing with it, the most important measures lie in prophylaxis—diet, purgation, and strengthening the heart-power. 3. *The dietetic treatment of diabetes*, of which the chief direction is a diet of albumen and fat, taking care not to overburden the stomach, and absolute withholding of carbohydrates. Milk, whether pure or skimmed, is forbidden; only curds allowed. Milk sugar has been held to be harmless, but this is at least doubtful. Worm Müller thought that in the diabetic it is converted into grape-sugar, whereas, in the healthy, copious milk-drinking is followed by slight excretion of lactose in urine. Recent researches prove that in health it appears in the urine partly as lactose and partly as glucose and galactose, in the slightly diabetic as large quantities of the latter, and but small amount of lactose, so that there is no essential difference. Abstinence from food for twenty-four hours with a view to diminish the excretion of sugar has no curative effect. Exercise is strongly recommended, especially in corpulent diabetics, with much uric acid in the urine; but excess is here also to be avoided. Mental rest is of chief importance. Dr. HOFFMANN (Dorpat) said that in the definition of the disease glycosuria cannot be separated from diabetes, in which there are no invariable anatomical changes. Hence various forms of diabetes are distinguished. Although "pancreatic diabetes" must be discarded, yet one may recognise a "neurogenic diabetes" as distinct from the "constitutional." He had collected eighty cases in which diabetes was ascribed to cerebral and spinal concussion and other traumatism, cases which agreed in the fact of injury, lack of heredity and prodromal nerve disorder, absence of tendency to furunculosis or arthritis; no polyphagia or polydipsia; no cataract; cases not of long duration, and often terminating in recovery. Every grade, from the mildest glycosuria to the severest diabetes, is represented in this series. Contrasted with such cases is the diabetes of the corpulent, with furunculosis, cataract, arthritis, very chronic course, and rare recovery. In treatment, too, the division into the accidental and constitutional groups is desirable, and is more valuable than that into mild and severe cases. The accidental forms —where curable—yield to animal diet; the constitutional, although showing an abatement of glycosuria upon such diet, exhibit other symptoms which are unfavourably affected by the restriction. Tonics—as iron, cod-liver oil, and quinine, and above all the Carlsbad cure—are suitable. Alkalies, of value in some cases, are useless or harmful in others. Opiates have latterly unfortunately been placed in the background, but their value is undeniable; only small doses should be given. Salicylic acid can be used with advantage in mild cases; in some cases it must be cautiously prescribed.—Dr. VON MERING (Strasburg) advocated muscular exercise, the muscles utilising the sugar and sparing the nitrogenous material; in one case five or six hours' heavy work produced a diminution in the urinary sugar from 50 to 5 grammes.—Dr. FINKLER (Bonn) had failed to induce glycosuria by ligature of the pancreatic duct or extirpation of the gland, by intravenous or intraperitoneal injection of pancreatic ferment. If diabetes is connected with the digestive function there must be other factors than lack of secretions. Some have attributed it to diseases of the cœliac plexus, and changes are often found therein. That the nervous system has to do with diabetes is shown in the reflex production of glycosuria by stimulation of the intercostal nerves, as well as other experiments proving that sensory nerves act reflexly upon the conversion of carbohydrates.—Dr. BINZ (Bonn) said he had found that injection into the blood of dogs and cats of neutral or faintly alkaline sodic butyrate caused coma and fatal paralysis. This was not due to concentration of the blood, for the same amount of sodic chloride or acetate gave rise to no such symptoms. The research confirmed the views of those who regarded oxybutyric acid as one of the causes of diabetic coma.—Dr. BAUMLER (Freiburg) pointed out that albuminuria of diabetes was of various pathogenesis and import; in some cases —fatal from carbuncle or pneumonia—the albuminuria was due to a bacterial nephritis. In the diabetes of the corpulent it may be due to chronic changes in the vessels, heart, &c. He asked for reports on the effect of von Duhring's treatment, consisting in the free administration of carbohydrates.—Dr. HERTZKA (Carlsbad) pointed out that diabetes was not a disease, but a symptom like icterus, and was evoked by manifold lesions, especially of the nervous systems. A man may therefore be a diabetic without excreting sugar. The dermatoses which precede glycosuria depend on the diabetic diathesis.—Dr. NAUNYN (Königsberg) had seen the best results from restricted animal diet, and had not observed any ill effects from it.—Dr. SCHNEE (Carlsbad, Nice) related a case of diabetes in a child whose father had suffered from syphilis. It was cured by mercurial treatment. Encouraged by this case he had prescribed mercury in seventy other cases, and in fifty-three the diabetes was cured.

A paper was then read by Dr. v. MERING upon Experimental Diabetes, in which, after alluding to previous work which indicated the part played by the glycogenic function of the liver, he described experiments with a glucoside—*phloridzin* ($C_{21}H_{21}O_{10}$), extracted from the root-cortex of fruit trees,—which, taken into the stomach, excites diabetes, in proportion to the dose administered. Whilst curare fails to produce glycosuria in starving animals, phloridzin succeeds; and to show its independence of the liver, he administered the substance to animals in whom the hepatic function had been destroyed by phosphorus. Sugar appeared in the urine in such animals, and also in geese after the liver had been extirpated. In starvation diabetes from phloridzin is accompanied by increased excretion of urea; in animals kept on flesh diet there is no such increase; and in this respect, as well as in the amount of sugar in the blood, this form of artificial diabetes differed from the actual disease. The author believed that renal changes formed an important factor in glycosuria.

Dr. FINKLER (Bonn) read a paper on the Treatment of Diabetes by Massage. In thirteen cases there was notable diminution in the amount of urinary sugar—e.g., from 400 to 120 grammes per diem,—the favourable result being attributed to increased metabolism. These results were obtained on a mixed diet, and the method was one suitable for patients incapable of active muscular exercise.

Professor STOCKVIS, in his reply, strenuously advocated restriction to animal diet, from which he had never seen any ill effects; but the diabetic should be careful not to over-eat himself, for derangements of digestion are dangerous.—Dr. HOFFMANN also replied, and pointed out in reference to v. Mering's experiments that phloridzin is a glucoside, and might therefore yield sugar directly.

Dr. RUMPF (Bonn) read a paper upon Syphilitic Diseases of the Vascular System. He pointed out that, whereas Heubner regarded disease of the intima as specific, Köster and Friedländer described arteritis obliterans as proceeding from an affection of the vasa vasorum, and therefore commencing in the media; whereas Baumgarten considered the adventitia to be the seat of such disease. A case was described which exhibited the rare condition of a gumma growing in the wall of the basilar artery causing thrombosis. Allusion was also made to forms of diffuse syphilitic infiltration. In

Digitized by Google

some specimens bacilli were found, but were regarded as associated with the regressive changes, and not as pathogenic.—Dr. LITTEN remarked that syphilitic vascular disease has no special characters. The anatomical changes were the same as those observed in chronic nephritis, and produced experimentally. The chief change is an endarteritis, which leads to obliteration of the channel, and the pathological result depends on the functional importance of the affected artery. A special feature in disease of the cerebral vessels is the rapidity with which cure follows mercurial inunction.—Dr. RUMPF replied by pointing out that his case was not one of simple chronic endarteritis, but of a gumma due to the localised action of the virus.

Dr. KNOLL (Prague), read a paper on Respiratory Innervation. According to Langendorff and Nitschmann the automatic respiratory centre resides in the spinal cord, the medulla having only a regulating function; the arrest of breathing on separation of the medulla being attributed to stimulation of depressor fibres; but the more recent experiments of Rosenthal tend to confirm the older notion that the respiratory centre is situated at the end of the calamus scriptorius. The centre is stimulated mainly through the blood, but whether from excess of carbonic acid or lack of oxygen is an open question. The subject of so-called blood-apnœa by excess of oxygen was discussed, the excitability of the centre being lowered thereby. The notion of a special heat-dyspnœa was rejected, it being shown that clinically there may be very high temperatures without any influence upon respiration. The nerve-paths of respiratory stimuli were enumerated, and the reflex effects of irritation of the nasal and laryngeal mucous membranes especially mentioned. Traube's view that excess of carbonic acid in the lungs causes a centripetal irritation of the vagus is disproved by the fact that the presence of carbonic acid in the lungs does not excite inspiratory movements.

Dr. UNNA (Hamburg) read a paper on Leprosy. Mention was first made of the fact observed by Lutz that the bacillus leprœ is really composed of rows of cocci, and should therefore be termed streptococcus, and that by employing various combinations of reagents (iodine, iodide of potassium, hydrochloric acid, peroxide of hydrogen) in Gram's method of staining, it was found that only when there was free or nascent iodine the coccus structure become manifest. Reference was also made to the treatment of leprosy by an ointment made with reducing agents, especially pyrogallic acid (10 per cent.), followed by icthyol.—Dr. TOUTON (Wiesbaden) stated that he had been enabled to demonstrate lepra-bacilli within cells and even within the lumen of sweat glands. He also asked whether Dr. Unna had examined the blood for bacilli, and whether such observations were made during or in the intervals of the eruption of lepra-nodules. He did not agree with Dr. Unna's histological methods, which were also characterised by Dr. NEISSER (Breslau) as unsuitable, and their results as incorrect and artificial.

(To be concluded.)

DR. RICHARDSON'S LECTURES ON ANIMAL OR VITAL MECHANICS.

MATERIALS FOR CONSTRUCTION.

THE second lecture of the above course, delivered on Monday, the 10th inst., before the Society of Arts, was devoted to the subject of the materials used by Nature in her mechanical works. These, the lecturer said, were so distinctive that we might from them form a fair conception of the physical condition of the planet at the time when natural mechanics began to have an existence. The number of parts entering into the natural constructions—fewer than those used by man in his works—were considered by the lecturer, first from their elementary forms and afterwards from the compounds produced by the elemental combinations. The elements used by Nature were divided into four groups:—(*a*) The gases: oxygen, hydrogen, nitrogen. (*b*) The non-metallic solids: carbon and sulphur. (*c*) The metals: calcium and iron. (*d*) The metalloid: phosphorus. The respective uses of these elements were briefly defined, with the explanation of an experiment made by Dr. Richardson in 1869, in which all the elements, except the carbon, that formed the body of an animal, a smelt, were dispersed, by the immersion of the body of the dead animal under molten lead. The carbon remained intact, and floated to the surface of the molten lead in the precise form of the animal, as its mechanical elementary skeleton, the solid basis of its construction. The uses of the elements are fairly known, except in regard to the metal iron. Iron, the lecturer said, is essential to some physical vital purpose, but what that purpose is he could not venture to state. It had been thought that iron had some relation to the colour of the chief fluid of animal organisms, the blood; iron had been supposed to be a carrier of oxygen; he had himself supposed that it might be a conductor of an electrical current; but against each and all of these views there were objections which at present were unanswerable.

From the elements Dr. Richardson passed to the compound structures formed by elemental combinations and used by Nature in her mechanics. He classified such compounds for study into seven great groups: (1) The gelatinous; (2) the resistant or bony; (3) the contractile—muscular; (4) the transparent—lenses and humours; (5) the receptive—nervous centres, screens, and cords; (6) the elastic—elastic tissue, wherever distributed; and (7) the aqueous—blood, fluid secretions, fluid excretions. The organs and mechanisms made or formed from the compounds thus specified were now passed under review, and by the electric light there was shown on the screen a large number of illustrative designs, many of them direct photographs from the natural parts themselves. Under the first division of compound structures the membranous structures were surveyed as investments, as valves, as tubes, and as basements; they were followed by views of ligaments, cartilages, tendons, and fascia, and so on through the other groups, osseous, muscular, lenticular, nervous, and elastic. In the course of the verbal descriptions which accompanied the illustrations, the lecturer indicated how the character of a structure might be changed by the introduction into it of even one new element, such as sulphur or phosphorus. He dwelt also on what may be called the natural choice or selection of elements for particular objects, as the light, malleable, strong metal calcium for the composition of the solid resistant structure of bone. He exhibited a carefully prepared table in which the elements used by man in his mechanical inventions were shown to exceed in number those of Nature, while including all that she uses in her work; then, dwelling on the notion of the ancient philosophers, that natural mechanisms were made out of four elements—air, water, earth, and fire,—he explained that in a general sense the ancients were correct: for air yielded oxygen and nitrogen; water yielded oxygen and hydrogen; the earth yielded oxygen, calcium, sulphur, phosphorus, iron, and carbon—altogether the material elements most wanted; while fire, or the motion which puts these elements into work, completes the series, and yields that endowment of vital property which leads to structure, form, independent action, motion of dead matter, life itself as manifested in its varied and infinite phenomena.

A DAY WITH PASTEUR.

WE have been favoured by Dr. G. H. Brandt with the following description of a visit he recently paid to M. Pasteur at the École Normale:—

As rabies and Pasteur are the order of the day, it may be interesting to many of your readers to know how things are carried out at the École Normale. The patients, who have come from different parts of France and from abroad, reside in small hotels and lodging-houses in the neighbourhood, and have to come every morning at eleven o'clock to the laboratory to be inoculated. I am sorry to say that the waiting-room and inoculating-room are very small and very crowded, not only with patients, but with a number of medical men who come to witness the proceedings. Pasteur is at the door with his list in hand calling out for the patients of the different series who have to be inoculated. Series No. 1 is that which has to be inoculated for the first time, No. 2 for the second time, and so on. At one end of this small room is a table on which stand different glasses covered with a piece of gutta-percha sheeting, which contain the different

Digitized by Google

solutions of virus in sterilised broth. The inoculator has two assistants—one fills and hands him the syringe, the other helps the patient. To avoid the trouble of undressing, the patients lift their shirt from over the left side, thus exposing the left flank; the inoculator seizes the skin, lifts it up, plunges the needle deeply into the areolar tissue, and presses the piston down to the end. One gramme of attenuated virus is thus lodged under the skin. One hundred and ten patients go through this operation every morning. The first inoculation is made with virus that has been kept in broth for fourteen days, the second inoculation with virus of thirteen days, and so on, until at the end of ten days a virus of five days' attenuation is used. This completes the ten inoculations, which are supposed to be sufficient to preserve the patient from hydrophobia. In the cases of the Russians who were so severely bitten by a wolf, M. Pasteur thought it right to repeat the series of ten inoculations three times over. I saw the photographs of the unfortunate inhabitants of Smolensk, who were completely disfigured by the fearful lacerations of the face; one of them, a priest, had his under lip torn away; another had still a fang of the wolf stuck in his malar bone; these are still alive, but, as you know, three have since died. It is well to mention that these unhappy men only reached Paris fifteen days after the bites. *Déjeuner* puts an end to the morning work, and at 2 P.M. M. Pasteur is in his laboratory, surrounded by medical men from all parts of the world—Americans, Russians, Germans, Swiss, Portuguese, &c. We first went to the basement, where the rabbits are kept in wire cages—some to be inoculated, others which have been operated on; of these there are three or four dying or dead. The mode of death in the rabbit is quite different from that of man—they die of paralysis, without a struggle; however, in some very rare instances you see a rabbit die of symptoms resembling those found in the human being. Two dead rabbits are taken up daily to the laboratory. The spinal marrow is taken out, and cut into pieces about four inches long; one end is attached to a piece of fine wire, the other end of the wire being fixed to an appropriate stopper, and placed in a prepared glass bottle. The preparation of the bottle consists in heating it to about 150° C., cotton-wool being placed in the mouth, and at another opening at the bottom of the bottle. A thick layer of caustic potash covers the bottom of the bottle. A few hours after the piece of medulla has been placed in the bottle it acquires a glazed appearance, as if it had been varnished. A piece of this spinal cord is placed in sterilised broth and kept for fourteen days; this serves for the first inoculation, as mentioned above. The operation of inoculating the rabbits is done in the following way: A healthy rabbit is placed on a board lying on his abdomen; his hind legs are fastened to two lateral pegs, and the same is done to the fore-paws. The hair is cut off his head to the extent of about half-a-crown. Chloroform is given until the animal is quite insensible. A clean incision is made lengthways with a sharp bistoury, previously dipped in a solution of carbolic acid. The lips of the wound are kept apart with an eye speculum or dilator, any blood is mopped up with fine blotting-paper dipped in carbolic acid solution, and a revolving trephine is placed perpendicularly on the bone; in a few turns a small disc of bone of about the size of a threepenny piece is cut through, and extracted with a curved needle, also disinfected. The dura mater is thus exposed. A fine Pravaz needle is then inserted under the membrane, and two or three drops of a strong virus-solution is injected. The speculum is removed, the skin sewn up, the ligatures undone, and the rabbit is allowed to come to, and is placed in his cage. On the seventh day the rabbit begins to feel the effects of the inoculation, and dies invariably on the tenth day. Two rabbits are thus inoculated every day, and two die every day, so that a supply of virus is kept up for inoculating rabbits and patients.

Nothing can exceed the politeness and kindness of M. Pasteur in explaining and answering our numerous questions. He is completely wrapped up in his subject, and, contrary to what has been hinted by some authors, keeps nothing hidden from anyone. He generally finishes by saying, "Gentlemen, I have told you everything I know, you have seen all I do, and now you know as much as I do." As we were questioning him, a paper was shown him in which there was a paragraph which said, "We can place no reliance on M. Pasteur's work, as so many cases of rabies appear many months—eighteen, twenty, and even twenty-four—after the bite of a mad dog." To this M. Pasteur answers: "This is not good reasoning, for statistics show that the great majority of cases have an incubation period of from twenty to sixty days. Cases of rabies happening before the twentieth day are very rare, and those after the sixtieth day are still more rare, so that our treatment includes the majority of cases. Six months have elapsed since young Meister was bitten by a mad dog and treated by my system; he is alive and well. So that it is not fair to condemn a treatment because time has not allowed the extremely rare cases of long incubation to show the result of our treatment. Statistics also show that there are about fifteen cases annually of hydrophobia admitted into the Paris hospitals, followed by fifteen deaths. Since we have begun our treatment there has been only one case admitted; this case was not inoculated, and death was the result." To the unbelievers M. Pasteur says: "Wait; time will reveal many facts connected with this question; and it is only by continued experiments and constant observations, carried on for a considerable time on hundreds of cases, that we shall be able to arrive at positive and definite results."

It is satisfactory to know that no evil results have followed the numerous inoculations already made. Several of M. Pasteur's students have inoculated themselves with attenuated virus, and, barring a slight red areola formed over the seat of puncture, no unpleasant symptom has ever shown itself.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Balsall Heath Urban District.—In so far as vital statistics are concerned this district has a satisfactory record for 1885. On a population of 22,495 the general death-rate was 14·3 per 1000, that for the principal zymotic diseases was 0·9, and infants under one year only died at a rate of 10 per 100 births registered. But Balsall Heath is not always so circumstanced. Thus during the previous year the zymotic rate reached 4·15 per 1000, and Dr. Leslie Phillips urges his authority not to be deterred from providing a proper hospital for infectious diseases by reason of a temporary cessation of the diseases for which such provision is intended. As a matter of fact, it is precisely at such times that hospitals can be best and most economically constructed; those erected under emergencies cannot be properly considered in their details, and the hurry leads to extravagance. Some few non-fatal attacks of the infectious fevers occurred, and opportunity was taken to secure the remedy of such faulty sanitary conditions as they were found to be associated with. Water is unfortunately still derived from surface wells, but eleven of them were closed during the year, their contents being considered unfit for human consumption.

Middlesex and Herts combined Districts.—For the twelfth time Dr. C. E. Saunders presents an annual report on this important district, and it is satisfactory to read an expression of opinion to the effect that it is doubtful whether any body of combined authorities can show a better record of work than has been performed in this district during the past ten years. Such work has secured a great general improvement of health, the mortality from the more preventable diseases has been diminished, and by the improvement of dwellings much additional comfort has been secured. During the past decennium the general death-rate has been reduced from 18·6 per 1000 to 16·4 on a population of some 90,000, which represents, during that period, a saving of some 1800 lives. In the *Barnet Rural District* the sanitary state of South Mimms remains very unsatisfactory, nothing of a permanent remedial nature having been effected, but in other parts of the district benefit has resulted from the laying on of the Colne Valley water. In the *Barnet Urban District* we are glad to learn that improvement has been effected in the matter of supplying the closets with water, for the defects in this respect have in the past led to much nuisance from stagnation of offensive contents in the sewers. No death occurred from diarrhœa during the past year—a result which may be, at least in part, attributed to the improvements effected in the matter of scavenging. The *East Barnet Valley Urban District* maintains its reputation

Digitized by Google

for healthiness. There has been no fatal case of zymotic disease due to any local circumstances, and great improvements have been effected in the ventilation and the automatic flushing of the sewers; but the need for disconnexion of house drains in some parts of the district is still great. In the *Berkhampsted Rural District*, water is much needed at Long Marston, but hitherto the cost has been found to be prohibitive. The infectious hospital in this district has again been found to be useful for the purposes of the *Tring Urban District*, where the authority contract for its use. In this latter district some progress is being made with regard to the disposal of the sewage, but it is evident that Dr. Saunders thinks the interference of the inspector of the Local Government Board, who considered under-draining of the purification area to be an unnecessary expense, as a mistaken act of the central authority, and he points out in this connexion that the lower part of the area is already water-logged. Diphtheria occurred at Apsley End in the *Hemel Hempsted Rural District*, and the need for sewers in the town which gives its name to the district is becoming a more and more pressing matter. New buildings and their plans are well looked after by the authority. In the *Watford Rural District* the diphtheria prevalence which occurred in this portion of Hertfordshire caused ten deaths. The need for water was much felt in Abbotts-Langley, but a company are now about to meet that want. Certificates under the Public Health (Water) Act are always required in the case of new dwellings before they are allowed to be occupied. The *Welwyn Rural District* is one of the least populous of the rural districts in the kingdom, and it had a death-rate of only 6·8 per 1000 during the past year. Old houses are faulty by reason of dampness, and waterclosets not properly provided with water so affect the sewers that the latter stand in need of some means for their automatic flushing. Indeed, a public water service for Welwyn town is a prominent sanitary want. In the *Hendon Rural District*, Pinner suffered from imported small-pox, and the roadways about Harrow station render the neighbourhood scarcely habitable. Houses are found unfit for habitation in several villages and hamlets of the *St. Albans Rural District*, where accommodation for the working classes is much needed. But the authority have no bye-laws, and hence have no control over building operations. Action under the Labouring Classes Lodging-houses Acts is suggested in order to meet a pressing want. It will thus be seen that in the various districts we have referred to all the more pressing sanitary requirements are brought prominently before the authorities concerned, and that skilled advice is always available to secure the removal of such conditions as tend to the injury of public health in the combined area. Excellent work results from time to time, and further improvements are almost continuously being carried out.

Bollington Urban District.—We are glad to learn that the question of providing Bollington with a proper water-supply bids fair to be at last dealt with. It is a matter that has been allowed to drag itself over a somewhat long series of years, but an engineer has now advocated an entirely new gravitation scheme, which is regarded as more satisfactory than any of the schemes formerly submitted. Some cases of diarrhœa during the past year are regarded by Mr. Allen as having been associated, in point of causation, with impure water or defective drainage—conditions which, as far as is found practicable under existing circumstances, are removed on detection. Amongst the nuisances dealt with are some "badly-drained ashpits." Any drain to an ashpit is bad, and we trust the remedy applied has been to raise the floor of the ashpit well above the level of the surrounding soil, and then to cover it with a roof. In this way wetness of contents, and the resulting offensiveness, will be avoided, and no need will exist for any attempt at drainage.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6177 births and 3585 deaths were registered during the week ending May 8th. The annual death-rate in these towns, which had been equal to 19·8 and 20·2 per 1000 in the preceding two weeks, further rose last week to 20·6. During the first five weeks of the current quarter the death-rate in these towns averaged 20·2 per 1000, and was 3·2 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·6 in Derby, 14·7 in Norwich, 15·7 in Wolverhampton, and 16·5 in Huddersfield. The rates in the other towns ranged upwards to 26·0 in Portsmouth, 28·3 in Preston, 28·8 in Bolton, and 29·1 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 382 and 364 in the previous two weeks, were 367 last week; they included 141 from whooping-cough, 114 from measles, 41 from diarrhœa, 32 from "fever" (principally enteric), 21 from diphtheria, 18 from scarlet fever, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Huddersfield; whereas they caused the highest death-rates in Portsmouth, Bolton, and Preston. The greatest mortality from whooping-cough occurred in Salford, Birkenhead, and Brighton; and from measles in Oldham, Portsmouth, Bolton, and Preston. The 21 deaths from diphtheria in the twenty-eight towns included 9 in London, 3 in Liverpool, and 2 in Halifax. No death from small-pox was registered either in London or in any of the twenty-eight large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had slowly increased in the previous six weeks from 7 to 19, had further risen to 27 at the end of last week; 11 cases were admitted to these hospitals during the week, against 6 and 3 in the preceding two weeks. The Highgate Small-pox Hospital contained 2 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 319 and 296 in the previous two weeks, rose again last week to 309, but were 44 below the corrected average. The causes of 83, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Blackburn, Cardiff, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Bristol, Hull, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 20·5, 20·7, and 23·1 per 1000 in the preceding three weeks, declined again to 22·3 in the week ending May 8th, but exceeded by 1·7 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·3 in Paisley and 17·8 in Edinburgh and Leith, to 26·1 in Glasgow and 27·9 in Perth. The 550 deaths in the eight towns showed a decline of 21 from the numbers returned in the preceding week, and included 20 which were referred to whooping-cough, 17 to measles, 12 to diarrhœa, 8 to scarlet fever, 2 to diphtheria, 2 to "fever" (typhus, enteric, or simple), and 1 to small-pox; in all, 62 deaths resulted from these principal zymotic diseases, against 34, 46, and 51 in the preceding three weeks. These 62 deaths were equal to an annual rate of 2·5 per 1000, which was 0·4 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 15 and 21 in the previous two weeks, were 20 last week, of which 15 occurred in Glasgow and 4 in Aberdeen. The 17 deaths from measles showed a further increase upon recent weekly numbers, and included 13 in Edinburgh and 3 in Leith. The 8 fatal cases of scarlet fever also showed an increase upon the numbers in recent weeks, 7 being returned in Glasgow. The deaths attributed to diarrhœa, which had been 9 and 6 in the previous two weeks, rose last week to 12, and were double the number in the corresponding week of last year; 4 occurred in Dundee, 2 in Aberdeen, and 2 in Perth. The deaths referred to "fever" and to diarrhœa were considerably below the average, and the fatal case of small-pox occurred in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 100 and 123 in the previous two weeks, declined again last week to 108, and were 9 below the number returned in the corresponding week of last year. The causes of 73, or 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·3 and 24·4 per 1000 in the preceding two weeks, rose again to 27·8 in the week ending May 8th. During the

Digitized by Google

first five weeks of the current quarter the death-rate in the city averaged 27·5 per 1000; the mean rate during the same period did not exceed 19·0 in London and 18·6 in Edinburgh. The 188 deaths in Dublin last week showed an increase of 23 upon the number in the previous week, and included 14 which were referred to the principal zymotic diseases, against 16, 8, and 13 in the preceding three weeks; 7 resulted from whooping-cough, 4 from diphtheria, 2 from diarrhœa, 1 from "fever" (typhus, enteric, or simple), and not one either from small-pox, measles, or scarlet fever. These 14 deaths were equal to an annual rate of 2·1 per 1000, the rates from the same diseases being 2·1 in London and 3·3 in Edinburgh. The fatal cases of whooping-cough, which had been 4 and 5 in the previous two weeks, rose last week to 7. The 4 deaths referred to diphtheria also exceeded the numbers in recent weeks, and raised the number of fatal cases of this disease recorded in the past five weeks to 8, whereas only one was registered in the first quarter of this year. Seven inquest cases and 7 deaths from violence were registered. The deaths both of infants and of elderly persons exceeded the numbers returned in recent weeks. More than a quarter of the deaths were registered in public institutions. The causes of 20, or nearly 11 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

THE Queen has been pleased to give and grant unto Arthur James Wharry, Esq., Surgeon-Major in the Egyptian Army, Her Majesty's Royal licence and permission that he may accept and wear the Insignia of the Fourth Class of the Order of the Medjidieh, which His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan, has been pleased to confer upon him in recognition of his services whilst actually and entirely employed beyond Her Majesty's dominions with the Egyptian Army.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General William Henry Muschamp is granted retired pay, with the honorary rank of Surgeon-General; Surgeon-Major William Elgee, half-pay, is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major and Honorary Brigade Surgeon Owen William George, M.D., has been permitted to commute his retired pay.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of December 30th, 1884, Surgeon John Jennings has been placed on the retired list of his rank.

The following appointment has been made:—Surgeon Percy E. Maitland to the *Lion*.

INFANTRY MILITIA.—3rd Battalion, the Sherwood Foresters (Derbyshire Regiment): Surgeon W. A. Walker is granted the honorary rank of Surgeon-Major.

YEOMANRY CAVALRY (Dorset).—Surgeon G. W. Daniell is granted the honorary rank of Surgeon-Major.

ARTILLERY VOLUNTEERS.—1st Dorsetshire: The following officer is transferred from the 1st Hampshire Artillery Volunteer Corps, on its division into two corps—viz., Acting Surgeon P. W. G. Nunn, to be Acting Surgeon.—2nd Sussex: The following officers to be transferred from the 1st Sussex Artillery Volunteer Corps, on its division into two corps—viz., Surgeon R. V. Skinner, to be Surgeon; Acting Surgeon H. Colgate, M.D., and Acting Surgeon H. Habgood, M.D., to be Acting Surgeons.—3rd Lancashire: John Joseph Neville, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—4th Lancashire: John Alexander Mackenzie, Gent., M.B., to be Acting Surgeon; Surgeon William Hoyle resigns his commission.—24th Middlesex: Acting Surgeon H. M. Crookshank resigns his appointment.—2nd Perthshire (the Perthshire Highland): Acting Surgeon John Mackay, M.B., to be Surgeon; Acting Surgeon Peter McCallum resigns his appointment.—2nd Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Surgeon J. W. Taylor, M.D., is granted the honorary rank of Surgeon-Major.—1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment): Surgeon and Honorary Surgeon-Major W. R. H. Barker resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.—1st Dumfries: Thomas Davidson, Gent., M.B., to be Acting Surgeon.—18th Lancashire (Liverpool Irish): Surgeon J. Finegan, M.D., is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE SCHOOL BUILDINGS OF WILLIAM HUNTER.

To the Editor of THE LANCET.

SIR,—It is not long since you recorded the demolition of John Hunter's house at Earl's Court. In a few days the whole of the "school buildings" built by William Hunter in 1768 in Great Windmill-street—which you allowed me to describe in THE LANCET of Sept. 27th, 1884—will be removed to make way for the new thoroughfare from Piccadilly to Holborn. Yesterday I was in the Museum, which I first entered as a student some years ago. That room, the theatre, and dissecting-room will soon be only a matter of history. These buildings were used as a school until 1835. Here taught William Hunter, Hewson, Cruickshank, Baillie, Wilson, Brodie, Charles Bell, Herbert Mayo, and Cæsar Hawkins. For three years after the majority of the teachers migrated to St. George's Hospital in 1830, and Mayo to King's College in 1831. Mr. Gregory Smith, who died a few weeks ago, lectured for three years subsequently; he was the head of the school in Little Windmill-street. The dwelling-house, now a foreign café, still remains; it was built at the same time as the schools. Here William Hunter lived and died. He was succeeded by Dr. Baillie, who lived in it until 1799, when he resigned as physician to St. George's Hospital, and went to live in Lower Grosvenor-street, where he died in 1823. Mr. Wilson was the last connected with the school who lived in the house. This neighbourhood had long been a medical centre. Sir John Shadwell, physician to three sovereigns, lived in Great Windmill-street for many years, and died there in 1747. Dr. Willis, who attended the children of James II, when Duke of York, lived in St. Martin's-lane, and died there in 1675. Dr. Denman lived in Queen- (now Denman-) street, and delivered lectures on midwifery in his own house for many years. I should be glad to be informed where John Hunter lived after his return to England in 1763, until he succeeded his brother in Jermyn-street in 1768. I have heard that it was in Golden-square, but I can nowhere find any record of it.

I am, Sir, yours truly,

May, 1886. CHARLES HAWKINS.

"ROTHELN: A POINT OF DIAGNOSIS."

To the Editor of THE LANCET.

SIR,—Having just passed through an attack of the above complaint, perhaps it would be interesting to your readers to have an account of it, especially as it confirms the statement of Dr. Glover in your issue of the 24th ult. as to the implication of some of the cervical glands previously to the appearance of the rash.

On Tuesday, March 23rd, I visited a young patient who had the disease in a mild form, and having seen her only the once, can accurately give the incubation period in my own case—viz., seven days. On the following Thursday (March 25th) I felt a stiffness at the angle of the jaw on both sides, and, having a case of mumps at the time, I laughingly said to a friend that I hoped I was not going to have mumps, little thinking at the time that I was in for another infectious disorder. The stiffness continued, and on Friday, the 26th, I noticed that two or three of the glands on both sides were swollen and tender. This stiffness about the neck and tenderness of the glands continued until the rash made its appearance. On Tuesday evening, March 30th, I felt rather out of sorts, and had considerable aching of the eyes. I passed a fair night, and was able to do my work the next day, though feeling it an exertion. The aching of the eyes increased, so about midday I took a dose of quinine, thinking it was neuralgic, but without relief. At 7 P.M. I had a distinct rigor, and at 7.30 went to bed feeling very unwell, the pain in the eyes being very intense and shooting to the back of the head; I was also very hot and feverish. After passing a very restless night, I was astonished to find myself with a rash on the face, neck, and shoulders, which rapidly spread over the whole surface of the body except the hands and feet; the pain of the eyes was not relieved by the appearance of the rash. Next morning, Friday, April 2nd, the rash was

Digitized by Google

at its height, the face swollen, conjunctivæ injected, and the throat, soft palate, and gums puffed and sore; the hard palate was also very rough to the tongue and tender, and I feel confident I had the same rash in my mouth and throat as I had externally. On Saturday the rash was fast fading, the aching of the eyes had diminished, and the stiffness of the neck had disappeared; and on the following Monday I got up for a short time, though feeling very shaky; it was on that day that I first noticed desquamation taking place on the face. Nothing remains to be said except that I made a rapid convalescence. I am Sir, yours faithfully,

Mill-hill, N.W., May 5th. W. STROVER.

AMENDMENT OF THE PENAL CLAUSES.

To the Editor of THE LANCET.

SIR,—The following clause in the Medical Amendment Act of 1884 has unfortunately been omitted in the present Act:—

"On and after the said appointed day, if any person who is *not* a registered medical practitioner, and who practises or professes to practise, or publishes his name as practising medicine or surgery for gain, or who receives any payment for practising medicine or surgery—*(a)* uses the designation of or represents himself to be a physician, surgeon, doctor, or apothecary; or *(b)* uses any designation or description denoting that he is qualified by law to practise medicine, surgery, or midwifery,—he shall, on summary conviction, be liable to a penalty not exceeding twenty pounds."

It is too much to expect at present the passing of a law to prevent unqualified persons practising either medicine or surgery; indeed it is doubtful whether such a law will ever be passed; but it is not too much to expect, or indeed to demand, that legally qualified members of the medical profession shall have their titles protected by law. At present a quack can assume any title that he may feel disposed to adopt, provided that he does not pretend to be *registered;* and the burden of disproof, often well-nigh impossible, lies upon those who take action thereon. By the insertion of the above clause this assumption is rendered impossible. It is intended to bring the subject before Sir Lyon Playfair (and other members of Parliament who have expressed themselves favourable to this clause) before the Bill reaches the committee stage, on Monday, the 17th inst., and if necessary petition the House of Lords in favour of the clause. All members of the profession who are in favour of its insertion will greatly assist if they will signify their acquiescence to me *without delay* either by post-card or letter.

I am Sir, yours &c.,

Liverpool, May 11th, 1886. ARTHUR WIGLESWORTH.

*** We entirely sympathise with the purpose of those who have drawn the above clause. Mr. Wiglesworth is chairman of the Liverpool Medical Defence Association, and speaks on the strength of much experience of the weak points in the clauses of the present Act. A Bill with a similar object is already before the House, introduced by Mr. John Morgan Howard, member for the Dulwich division of Camberwell. This Bill further contains a clause meant to suppress dispensaries which purport to be conducted by registered practitioners and are worked chiefly by unqualified assistants. This is a great evil, and needs more stringent legislation than we either have or are likely to get. The clause of Mr. Howard's Bill is perhaps a little too sweeping, but it is in the right direction. Practitioners who approve of the clause to which attention is drawn by Mr. Wiglesworth will do well to signify their approval by post-card to him.—ED. L.

ROYAL COLLEGE OF PHYSICIANS.

To the Editor of THE LANCET.

SIR,—The election this year of Fellows to the College of Physicians disappoints those who had hoped for an extension of it on a generous scale to the older Members. Your kindness allowed of attention being drawn to this proposition as early as last October, but possibly then too late to affect the recent election. If so, the sexennium of our present President might at its close be gracefully signalised by liberal selection to the fellowship of the older Members, the length of whose hospital experience, as well as entrance to the College, may measure within a decade of his own, and most of whom were Members before the youngest of the recently elected Fellows had been born. Be it understood, however, no fault is found with the early elections, but it is felt to be desirable as well as equitable, since the College has ceased to be merely metropolitan and become national, that its status of fellowship should be placed within the reach of industry and integrity after a reasonable term of membership. I am, Sir, yours truly,

May 10th, 1886. A MEMBER PRIOR TO 1859.

"AFTER-CARE" OF MENTAL CONVALESCENTS.

To the Editor of THE LANCET.

SIR,—Your previous kindness in calling attention in your columns to the need of "after-care" on behalf of many poor and friendless mental convalescents induces me to trouble you with another brief communication.

In succession to Lord Shaftesbury, who took much interest in the subject of "after-care," and attended several successive anniversaries of the Association, Lord Brabazon has accepted the office of President. Several well-known physicians, specially experienced in the treatment of mental maladies, have evinced personal interest in a project for fostering the convalescence of persons recovering from these disorders. It is intended, when the amount of funds permit the undertaking, to open a "home," both for the reception of a few convalescents and also as a centre of the Society's operations. Lord Shaftesbury expressed an opinion that such a home was necessary. No existing convalescent home (among more than 200) professes to receive persons recovering from general mental derangements. Many homes, by their rules, exclude this class of convalescents from the benefits which they provide for persons convalescing from ordinary maladies. It should be borne in mind that there are more than 60,000 patients (of whom the majority are women) in county asylums and kindred institutions. Many are physically as well as mentally invalided, requiring, on leaving asylums, "after-care" at least equally as much as convalescents from ordinary hospitals. Contributions would be received by Dr. Clay Shaw, hon. treasurer, Banstead, Sutton, Surrey; or by the Union Bank of London, Argyll-place, W. I would gladly reply to any communication.

I am, Sir, yours truly,

H. HAWKINS, Hon. Sec.

Chaplain's House, Colney Hatch, N., May 10th, 1886.

*** We heartily wish this very useful and humane enterprise success.—ED. L.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SUNDERLAND INFIRMARY.

THE spring meeting of the North of England Branch of the British Medical Association having been held at Roker (a pleasant watering-place in the vicinity of Sunderland) on the 21st ult., the Honorary Medical Staff of the Sunderland Infirmary invited the members to the infirmary, and entertained them to luncheon. Between eighty and ninety members availed themselves of the invitation and inspected the infirmary, which contains accommodation for 150 beds, and was much admired. The new wing has now been opened nearly two years, and was built in accordance with the most advanced ideas of hospital construction, and cost £10,700. The admissions of patients is untrammelled by any subscriber's recommendation, and a small sub-committee sits to see that improper persons are not admitted. This change from ticket to free admission has now been tried for eight years, has worked admirably, and has had the special effect of bringing to the infirmary acute medical cases. There is another feature that might be mentioned in connexion with the Sunderland Infirmary—namely, that for the last fourteen years it has been nursed by the sisters from the Protestant Deaconesses' Training Hospital, Tottenham, and the unanimous feeling of the Committee of Management and of the medical officers is that the nursing and management of the

Digitized by Google

sisters are highly satisfactory, and their self-denying labours above all praise. Another pleasing feature in connexion with the infirmary, which proves the success of its popular arrangements, is that the working classes contribute liberally.

NEW BATHS AND WASHHOUSES IN NEWCASTLE.

The corporation have erected, just lately, three sets of public baths and washhouses in different districts of the city, and two of these have been completed, and were opened by the mayor the other day. The arrangements are of the most modern and complete description, and the cost of the three establishments will be about £30,500. Each set of buildings contains one large swimming-bath, sixty feet in length and thirty feet in width. These baths are lined with white glazed tiles. Persons will not be permitted to enter the baths until their feet have been washed, and for this purpose a small foot-bath, with hot and cold water, is fitted up.

THE SANITARY CONDITION OF SCHOOL BUILDINGS.

The Corporation of Tynemouth have lately had a searching inspection of the whole of the schools of the borough carried out by the Corporation officials in conjunction with Mr. J. P. Spencer, C.E., of this city, and have published in a detailed report on the whole of the schools in the borough, both private and public, which goes to show that out of forty-five schools dealt with only two are stated to be in a satisfactory condition, the remaining forty-three, including the board schools, being all more or less defective in sanitary arrangements. The report contains in each case practical recommendations for remedying the defects, and the required alterations are in many instances being promptly carried out.

SANITARY DEFECTS IN HOUSES.

A builder in Newcastle having contracted to deliver a house in good sanitary condition to a merchant here, upon the occupation taking place one of the family suffered very severely from blood-poisoning, which led to an examination of the house drains; these were found to be very defective, and in the opinion of medical men clearly accounted for the illness. Legal proceedings were commenced for damages, which the builder found it prudent to arrest by the payment of £500. A few instances of this nature would do much to further a correct estimate of house sanitation in the "building mind."

NEWCASTLE SICK CHILDREN'S HOSPITAL.

The committee appointed by the Corporation have presented a report recommending a lease to be granted to Mr. John Fleming, of this city, of ground belonging to the Corporation in the suburbs, whereupon to erect a new children's hospital, Mr. Fleming having offered to erect the hospital and also to completely furnish it. It is to contain from sixty to eighty beds, and will probably cost not less than £16,000. There is at present a vacancy for a physician to the hospital, and in view of the expansion of the charity, there is likely to be more than usual competition for the post, as it will no doubt afford a good field for work and a certain introduction to practice. So far, the following are pursuing a very active canvass:—Dr. Coley, who is at present assistant physician, and has filled that post for four years; Dr. Limont, who is one of the physicians to the Newcastle Infirmary; and Dr. W. Robertson, of this city.

Newcastle-on-Tyne, May 11th.

EDINBURGH.

(From our own Correspondent.)

ROYAL HOSPITAL FOR SICK CHILDREN.

THE post of extra assistant-physician to this hospital, vacant through the resignation of Dr. Dyce Fraser, has been bestowed upon Dr. R. Mackenzie Johnston.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

At the last meeting of this Society, held on the 5th under the presidency of Dr. Batty Tuke, a large number of interesting specimens and cases were exhibited and some valuable papers read. A fifth was added to a series of cases recorded by Dr. Bruce of the deleterious effects of the inhaled fumes of bisulphide of carbon. In all the patients the same series of symptoms has been observed, the symptoms being chiefly those of alarming disturbances in the cerebrum, as evidenced by profound aberrations in the functional activity of the organs of special sense, with a general loss of trophic activity. The symptoms, though so serious in their aspect, disappear rapidly when the patient is removed from the vitiated atmosphere in which he has been working, and it seems that after his removal there is a steady process of elimination carried, on which relieves the system of the poison, leaving the patient perfectly restored to his lost or aberrant functions in from two to three weeks.—In an interesting paper Dr. Sloane communicated to the Society the results of a series of observations on the relationship which exists between the presence of goitre and the occurrence of pregnancy or menstruation. He drew attention to the frequency of a considerable enlargement of the thyroid tumour taking place in each of these conditions a corresponding diminution in bulk following their cessation; and he is inclined to think that these phenomena are in intimate connexion with some hæmopoiëtic function of the thyroid which becomes specially accentuated during the two conditions in which the enlargement of the gland is noticed. In the discussion which followed considerable doubt was thrown upon Dr. Sloan's view of the probable explanation of the phenomena, but his careful statistics received due credit as an important addition to the literature of the subject.—Dr. Byrom Bramwell read a paper describing a case of Meningeal Cerebral Hæmorrhage, occurring in a hæmophilic subject as the result of a fall. After a prolonged course, during which at first hemiplegia, and later optic neuritis were leading symptoms, the patient made a very good recovery, the paralyses having completely disappeared, and the sight being all but fully restored.

Edinburgh, May 11th.

GLASGOW.

(From our own Correspondent.)

UNIVERSITY REFORM.

DURING the last few years a great deal has been said and written about the reform of our system of university teaching, and the agitation with this end in view has been justified by reference to the many evils which are sure to grow up in the absence of a healthy competition in such teaching. Throughout the whole of the controversy it has been assumed, too hastily it seems, that the professors as a body were against any change in the existing system. It has come, therefore, with the shock of a pleasant surprise to find the General Council of Glasgow University adopting, by an overwhelming majority, a scheme of teaching reform which may be pronounced thoroughly radical or even revolutionary, and to find that this scheme is introduced and warmly supported by the professorial party. The plans so ably defended by Prof. Edward Caird at the last meeting of the General Council may be shortly described as having for their object intra-mural expansion as distinguished from unlimited extra-mural teaching. It is suggested that there should be a widening of the curriculum and a greater choice of subjects for the M.A. degree; that various new chairs should be instituted (modern languages, history, political economy, education, &c.); that in the Faculty of Medicine a chair of pathology and a lectureship on mental diseases should be at once founded; that, in addition to the present chairs, junior professorships and lectureships in the subjects already taught in the University should be instituted as required, the lectures of all these professors or lecturers qualifying *pro tanto* for degrees; that while due provision is made for present life interests, all class fees should go into a common fund, and that all the teachers should be paid by fixed salaries. The scheme here sketched is a tolerably close imitation of the German system, the extraordinary professors, professors, and *privat docenten* of Germany being represented by the professors, junior professors, and lecturers. How far it is capable of application to Scottish university life is not yet clear; but meanwhile it has given rise to much discussion and speculation. On the whole, it has been well and even warmly received, the principal malcontents being those engaged in extra-mural teaching with whose work it seems

Digitized by Google

to some extent to interfere. On the other hand, the professors and assistant professors, and generally all those who have the welfare of the University at heart, have given the plan their warm support. Unfortunately the General Council has no executive power—it can only deliberate and advise; but it seems certain that in any alterations to be made in the government of our universities effect will be given to the expressed wishes and convictions of the members of the Senate and the majority of the University graduates. Further, the government of any one Scottish university is very much bound up with the government of the other three, and thus cannot be readily altered. Again, the monetary difficulty is one which will not be easily overcome; it does not seem very practicable to take the teacher's "fixed salaries" out of a fee fund, which from its very nature is itself anything but a fixed quantity. Visions of private munificence, and even of substantial Government aid, are now floating before the minds of the more enthusiastic advocates of the measure; it is to be hoped that they are not doomed to disappointment.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual elections for President, Vice-President, Secretary, and Council will shortly take place. There are at present two candidates in the field for the Vice-Presidency, which will then be vacated by Mr. Stokes—viz., Mr. Corley, Lecturer on Surgery in the Carmichael Medical College, and Dr. Frazer, late Examiner in the College of Surgeons; and it is believed that both gentlemen will go to the poll. Among the candidates for Council I may mention the name of Mr. Kendal Franks.

ADDRESS AND PRESENTATION TO DR. JAMES MOORE, LURGAN.

This gentleman was recently presented with a very handsome silver salver, having an appropriate inscription, by his friends from Dungiven, where he formerly practised, as a mark of esteem and affection. The salver was accompanied with an address illuminated on vellum. It must be very gratifying to Dr. Moore that these gifts were subscribed to by members of all classes, creeds, and parties.

DUBLIN ORTHOPÆDIC HOSPITAL.

A grand military and fancy dress ball will be held on the 24th inst. in aid of the funds of this institution. The ball will be under the patronage of the Lord-Lieutenant and the Countess of Aberdeen, the Prince and Princess Edward of Saxe-Weimar, and other distinguished persons. Last year an entertainment of a similar kind took place, and as a result a very considerable sum was obtained for the hospital.

COUNTY DONEGAL INFIRMARY.

Two sections of the new infirmary at Lifford have been completed within the past two years; and the third and last section has now been commenced. This latter is for females, and will contain three wards, with nurses' rooms, operating theatre, bath rooms, &c. The wards will be thoroughly ventilated, and it is intended to line the walls for five feet above the ground with white glazed brick, and the remainder and the ceilings in cement, so as to avoid all risk of infection by absorption, while all can be kept clean by washing with soap and water.

BARRINGTON'S HOSPITAL, LIMERICK.

The managing committee of this institution met last week and made the following appointments:—Visiting Physicians: Drs. Holmes and Graham. Visiting Surgeons: Messrs. Robert Barry, M. O'Connor, John Holmes, and M. J. Nolan. Consulting Physicians: Drs. M. J. Malone, Myles V. Bourke, and George Myles. Consulting Surgeons: Messrs. Thomas Kane, R. R. Gelston, T. J. Gelston, and F. W. Connor. Resident Physician: Dr. George Browning.

BELFAST WORKHOUSE.

The half-yearly report of the Local Government Board inspector of this workhouse is a very satisfactory one, and the management now in operation is giving general satisfaction. During the past half-year the inmates have been healthy, and the town has been free from any epidemic disease. The addition to the lunatic department is now nearly finished, and it is believed that it will answer the purpose for which it was erected. The report speaks highly of the general condition of the workhouse.

Dublin, May 11th.

PARIS.

(From our own Correspondent.)

DEATHS OF DR. HENRI LEGRAND DU SAULLE AND DR. LOUIS-ANTOINE GILLEBERT DHERCOURT.

ON Friday morning I received a notice of the death of Dr. Henri Legrand du Saulle, which occurred as his residence in Paris on Wednesday, the 5th inst., after only two days' illness, from cerebral congestion. He was only fifty-six years of age. The deceased physician was a distinguished member of the profession, and held a high position in Paris, as may be seen by his titles: Physician to the Salpétrière Asylum, Principal Medical Officer of the Prefecture of Police, Expert to the Tribunal Courts, Member and one of the Founders of the Society of Medical Jurisprudence, former President of the Medico-Psychological Society of Paris, and Officer of the Legion of Honour. After having edited the "Gazette des Hôpitaux" for seven years in conjunction with the late Professor Trousseau, he founded with Drs. Gallard and Devergie the Société de Médecine Légale. He was the highest authority in France on mental and nervous affections, on which subjects he published several works. Among them may be cited, "La Folie devant les Tribunaux," "Les Manuel Pratique de Médecine Légale," and "Le Délire des Persécutions." The last-named work was inspired by the events of the second siege of Paris in 1871. It contains an interesting description of the psychological aspect of the Commune, and the author explains in vivid terms how the Parisians, the women particularly, were terror-stricken. With minds thus unhinged, and being also under the influence of drink, the Communists were incited to commit the horrible crimes that are ascribed to them. The funeral of Dr. Legrand du Saulle took place on Saturday last, the service being performed at the Cathedral of Notre Dame, in the presence of a large assembly, where the learned societies to which the deceased belonged, the prefecture of police, and the magistrature were officially represented. After the service the body was conveyed to the Cemetery of Montparnasse, where it was temporarily deposited for further removal to his native town.

Another well-known physician, Dr. Louis-Antoine Gillebert Dhercourt, has just passed away. He died at Enghien, near Paris, where he had settled in practice during the whole of his professional career, and where he will be very much missed by the invalids who resort to that watering-station during the summer. The deceased was seventy-eight years of age; he was President of the Medical Society of Paris.

M. PASTEUR.

In completion of his report, submitted about a month ago to the Academy of Medicine, M. Pasteur read another at the meeting of last week, in which he expressed himself as follows: "On April 12th last the number of persons inoculated for hydrophobia was 726; at the present moment (April 4th) it is 950. Since the time that that report was presented I have had a confirmation of what I then stated—viz., that the mortality caused by the bite of rabid wolves was very considerable. Very frequently this mortality is 100 per cent., and the duration of the incubation is always very short, being sometimes only thirteen or fifteen days. Very frequently also this duration does not exceed eighteen to twenty days, the bite of the dog being rarely of such short duration. Six deaths have occurred among those who have been inoculated, without including the little girl Pelletier, who died at the commencement of these inoculations. The six cases were Russians, five of whom were men bitten by wolves, and the other a woman bitten by a mad dog, all of whom died of hydrophobia, and in whom also the wounds were of a very grave nature. These statistics present a great deception to hostile persons—such, for instance, as the anti-vaccinators. This is my profound conviction, and I believe that there can be no possible doubt regarding the method, as the persons adverse to it cannot contest the results which I have indicated, any more than the experiments which repose on the *ensemble* of these results."

Paris, May 11th.

Digitized by Google

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council held on Thursday last, Mr. Bruce Clarke attended and received the Jacksonian Prize.

The President, Vice-Presidents, and Mr. Marshall, representative of the College in the General Medical Council, were appointed to take any action which they may deem requisite in regard to the Medical Acts Amendment Bill.

The report of the Council of the Royal College of Physicians with reference to the title of Doctor, which has been laid before that College, was brought before the Council, and referred to the consideration of the Committee already appointed to report upon.

The resignation of Mr. Henry Moon, Examiner in Dental Surgery, was received with regret.

Mr. Marshall was reappointed representative of the College in the General Medical Council for five years from the 9th of June next.

Information was received from the Foreign Office of an International Congress on Hydrology and Climatology to be held in Biarritz in October next.

A letter was read from the Chancellor of the University of Adelaide, requesting recognition of the course of lectures of that University for the First and Second Examinations. This was referred to the Committee of Management.

Obituary.

TIMOTHY LEWIS, M.B., OF NETLEY.

IT is with much regret we announce the death of the above-named gentleman, which took place on the 7th inst., at his residence, Bywood, Woolston, after a brief illness, extending over a week only. The late Surgeon-Major Lewis was assistant professor of pathology in the Army Medical School, to which institution and to the medical staff of the army his death will be a great loss. Dr. Lewis's reputation as a scientist was European; as a microscopist he was *facile princeps*. Less than a fortnight ago the Council of the Royal Society included his name in the list of those recommended for election as Fellows in June next in recognition of his original investigations and contributions to science. When he passed through the Army Medical School as a probationer for the Medical Department of the Army, the professors recognised his aptitude for scientific investigation, and, along with Dr. David Cunningham, a probationer from H.M.'s Indian Medical Service, brought his name under the notice of the Secretary of State for War. The professors recommended that both the gentlemen named should be sent to Germany for a few months' training under some of the most accomplished pathological *savants* of that country. To this the Secretaries of State for War and India consented, and by the recommendation of the professors both gentlemen were sent to India, chiefly with a view to carry out investigations on the cause of cholera. This cause is yet one of Nature's secrets, which has evaded the researches of the ablest men who have sharply interrogated her; but while they failed to discover what was the main object of their search, like the brothers in the fable who dug in the garden for hidden treasure which was not there, their researches and labours were fruitful in other discoveries, with which the names of Lewis and Cunningham will, in the annals of science, be imperishably associated. The deceased gentleman was an occasional and highly valued contributor to our columns. It is needless to add that his death has caused profound grief in the great establishment to which he belonged, and of which he was so great an ornament. He had only just reached his forty-fifth year of age, and has left a widow and two children to mourn their loss.

DR. JOHN D. HAYWARD, of Liverpool, has, we understand, obtained a prize offered some two years ago by Dr. Prater for essays on the subject of Hydrophobia.

MEDICAL NOTES IN PARLIAMENT.

Medical Officers at Suakim.

IN the House of Commons on the 7th inst., Mr. Herbert Gladstone, in reply to a question by Mr. M. Henry, stated that three medical officers serving at Suakim had died, and that ten had been invalided. The medical officers of the British army were being removed from Suakim, as the British garrison was withdrawn.

The Rating of Charities.

On the 11th inst. Sir Julian Goldsmid brought in a Bill to exempt charities and hospitals from local rates.

Small-pox in Prisons.

In reply to Mr. Stanley Leighton, Mr. Childers stated that it was perfectly true that two prisoners suffering from small-pox had been removed from Shrewsbury Gaol to the Atcham Workhouse, a distance of five miles. He had no reason to doubt that the removal was, under the circumstances, expedient, and that all proper care was taken in the case. The prison is at present undergoing partial reconstruction, and there is no available space for the insulation of a case of this nature; moreover, the workhouse infirmary at Atcham is used for infectious cases, including small-pox cases. In reply to a further question, Mr. Childers said that it would partly depend on the condition of the prison whether, if a prisoner was affected with disease of this kind, he should be removed. In the present case it would clearly have been wrong to keep him in prison.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen, having passed the required examination, were admitted Members of the College on the 6th inst.:—

Birch, Edward Alfred, M.D. Brussels, Exmouth.
Dalton, Norman, M.D. Lond., Bentinck-street, Manchester-square.
Gerard, John, M.B. Aberd., Keppel-street, Russell-square.
Harris, Thomas, M.D. Lond., Mosley-street, Manchester.
Jones, Henry Lewis, M.B. Camb., Barnard's-inn, Holborn.
Lyon, Thomas Glover, M.D. Camb., King-street, Cheapside.
Neale, John Headley, M.B. Edin., Leicester.
Pearce, Walter, M.B. Lond., St. Mary's Hospital.
Pope, Frank Montague, M.B. Camb., Leicester.
Rutherfoord, Henry Trotter, M.B. Camb., Bedford-gardens, Kensington.

The following gentlemen were admitted Licentiates of the College on the 6th inst.:—

Baker, Walter Robert, Pine Villa, Quex-road, Kilburn.
Barrett, Robert Hasby, Elms-road, Dulwich.
Barrett, Sidney Edward, London House, Stepney.
Berrill, Alfred, Olton, Birmingham.
Bidwell, Lawrence, Lee-terrace, Blackheath.
Bonnefin, Fernand Henry, St. Paul's-road, Camden-square.
Buckell, Edward, Romsey.
Chisholm, Murdoch, Paris-street, Lambeth.
Clark, Francis William, Fairfield-road, East Croydon.
Clay, William Rudolph, Westwick-gardens, Hammersmith.
Coker, Owen Cole, Uxbridge-road.
Colquhoun, William Brooks, Evering-road, Upper Clapton.
Copeman, Sydney Arthur Monckton, York-road, Lambeth.
Daly, Stephen Joseph, Monastervin, Ireland.
Davidson, Harold, Claremont-road, Forest-gate.
Davis, George William, College of Medicine, Newcastle-on-Tyne.
Davis, Weston Peel, Gloster-terrace, Bayswater.
Dickinson, Charles, Sloane-street.
Dobson, Leonard Chas. Talbot, Holmesdale, Grange-park, Ealing.
